You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ←
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can specify many of the options described in this section either in an instance, or at a global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <QSF variable name> <value>
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <QSF variable name> <value> \  
-to <instance name>
```

If the <value> field includes spaces (for example, “Standard Fit”), the value must be enclosed by straight double quotation marks.

## Initial Compilation Settings

The Quartus Settings File variable name is used in the Tcl assignment to make the setting along with the appropriate value. The Type column indicates whether the setting is supported as a global setting, an instance setting, or both.

 This chapter refers to timing settings and analysis in the Quartus II Classic Timing Analyzer. For equivalent settings and analysis in the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* or the *Switching to the Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

Table 8–13 lists the Quartus Settings File variable name and applicable values for the settings discussed in “Initial Compilation: Required Settings” on page 8–3.

Setting Name	Quartus Settings File Variable Name	Values	Type
Device Setting	DEVICE	<device part number>	Global
Use Smart Compilation	SPEED_DISK_USAGE_TRADEOFF	SMART, NORMAL	Global
Optimize IOC Register Placement For Timing	OPTIMIZE_IOC_REGISTER_PLACEMENT_FOR_TIMING	ON, OFF	Global
Optimize Hold Timing	OPTIMIZE_HOLD_TIMING	OFF, IO PATHS AND MINIMUM TPD PATHS, ALL PATHS	Global
Fitter Effort	FITTER_EFFORT	STANDARD FIT, FAST FIT, AUTO FIT	Global
Router Effort Multiplier	ROUTER_EFFORT_MULTIPLIER	Any positive, non-zero value	Global
Router Timing Optimization level	ROUTER_TIMING_OPTIMIZATION_LEVEL	NORMAL, MINIMUM, MAXIMUM	Global
Final Placement Optimization	FINAL_PLACEMENT_OPTIMIZATION	ALWAYS, AUTOMATICALLY, NEVER	Global

## Resource Utilization Optimization Techniques (LUT-Based Devices)

Table 8–14 lists the Quartus Settings File variable name and applicable values for the settings discussed in “Resource Utilization Optimization Techniques (LUT-Based Devices)” on page 8–25. The QSF variable name is used in the Tcl assignment to make the setting along with the appropriate value. The Type column indicates whether the setting is supported as a global setting, an instance setting, or both.

Setting Name	QSF Variable Name	Values	Type
Auto Packed Registers (1)	AUTO_PACKED_REGISTERS_ <device family name>	OFF, NORMAL, MINIMIZE AREA, MINIMIZE AREA WITH CHAINS, AUTO	Global, Instance
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Optimization Technique	<device family name>_OPTIMIZATION_ TECHNIQUE	AREA, SPEED, BALANCED	Global, Instance
Speed Optimization Technique for Clock Domains	SYNTH_CRITICAL_CLOCK	ON, OFF	Instance
State Machine Encoding	STATE_MACHINE_PROCESSING	AUTO, ONE-HOT, MINIMAL BITS, USER-ENCODE	Global, Instance
Preserve Hierarchy	PRESERVE_HIERARCHICAL_BOUNDARY	OFF, RELAXED, FIRM	Instance
Auto RAM Replacement	AUTO_RAM_RECOGNITION	ON, OFF	Global, Instance
Auto ROM Replacement	AUTO_ROM_RECOGNITION	ON, OFF	Global, Instance
Auto Shift Register Replacement	AUTO_SHIFT_REGISTER_RECOGNITION	ON, OFF	Global, Instance
Auto Block Replacement	AUTO_DSP_RECOGNITION	ON, OFF	Global, Instance
Number of Processors for Parallel Compilation	NUM_PARALLEL_PROCESSORS	Integer between 1 and 4 inclusive	Global

**Note to Table 8–15:**

(1) Allowed values for this setting depend on the device family that is selected.

## I/O Timing Optimization Techniques (LUT-Based Devices)

Table 8–15 lists the QSF variable name and applicable values for the settings discussed in “I/O Timing Optimization Techniques (LUT-Based Devices)” on page 8–97. The QSF variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Setting Name	Quartus Settings File Variable Name	Values	Type
Optimize IOC Register Placement For Timing	OPTIMIZE_IOC_REGISTER_PLACEMENT_FOR_TIMING	ON, OFF	Global
Fast Input Register	FAST_INPUT_REGISTER	ON, OFF	Instance
Fast Output Register	FAST_OUTPUT_REGISTER	ON, OFF	Instance
Fast Output Enable Register	FAST_OUTPUT_ENABLE_REGISTER	ON, OFF	Instance
Fast OCT Register	FAST_OCT_REGISTER	ON, OFF	Instance

## Register-to-Register Timing Optimization Techniques (LUT-Based Devices)

Table 8–16 lists the QSF variable name and applicable values for the settings discussed in “Register-to-Register Timing Optimization Techniques (LUT-Based Devices)” on page 8–52. The QSF variable name is used in the Tcl assignment to make the setting along with the appropriate value. The **Type** column indicates whether the setting is supported as a global setting, an instance setting, or both.

Setting Name	Quartus Settings File Variable Name	Values	Type
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Perform Gate Level Register Retiming	ADV_NETLIST_OPT_SYNTH_GATE_RETIME	ON, OFF	Global
Allow Register Retiming to trade off $t_{SU}/t_{CO}$ with $f_{MAX}$	ADV_NETLIST_OPT_RETIME_CORE_AND_IO	ON, OFF	Global

**Table 8–16. Register-to-Register Timing Optimization Settings (Part 2 of 2)**

Setting Name	Quartus Settings File Variable Name	Values	Type
Perform Physical Synthesis for Combinational Logic	PHYSICAL_SYNTHESIS_COMBO_LOGIC	ON, OFF	Global
Perform Register Duplication	PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION	ON, OFF	Global
Perform Register Retiming	PHYSICAL_SYNTHESIS_REGISTER_RETIMING	ON, OFF	Global
Physical Synthesis Effort	PHYSICAL_SYNTHESIS_EFFORT	NORMAL, EXTRA, FAST	Global
Fitter Seed	SEED	<integer>	Global
Maximum Fan-Out	MAX_FANOUT	<integer>	Instance
Manual Logic Duplication	DUPLICATE_ATOM	<node name>	Instance
Optimize Power during Synthesis	OPTIMIZE_POWER_DURING_SYNTHESIS	NORMAL, OFF EXTRA_EFFORT	Global
Optimize Power during Fitting	OPTIMIZE_POWER_DURING_FITTING	NORMAL, OFF EXTRA_EFFORT	Global

### *Duplicate Logic for Fan-Out Control*

The manual logic duplication option accepts wildcards. This is an easy and powerful duplication technique that you can use without editing your source code. You can use this technique, for example, to make a duplicate of a large fan-out node for all of its destinations in a certain design hierarchy, such as `hierarchy_A`. To make such an assignment with Tcl, use a command similar to [Example 8–1](#).

#### **Example 8–1. Duplication Technique**

```
set_instance_assignment -name DUPLICATE_ATOM \
    high_fanout_to_A -from high_fanout_node \
    -to *hierarchy_A*
```

## **Conclusion**

Complex designs have complex requirements. Methodologies for fitting your design and for achieving timing closure are fundamental to optimal performance of your design. Using the Quartus II design optimization methodology closes timing quickly on complex designs, reduces iterations by providing more intelligent and better linkage between analysis and assignment tools, and balances multiple design constraints including multiple clocks, routing resources, and area constraints.

The Quartus II software provides many features to achieve optimal results. Follow the techniques presented in this chapter to efficiently optimize a design for area or timing performance, or to reduce compilation time.

Feb. 2004 v1.0	Initial release.	—

## Introduction

The Quartus® II software offers power-driven compilation to fully optimize device power consumption. Power-driven compilation focuses on reducing your design's total power consumption using power-driven synthesis and power-driven place-and-route. This chapter describes the power-driven compilation feature and flow in detail, as well as low power design techniques that can further reduce power consumption in your design. The techniques primarily target Arria™ GX, Stratix® and Cyclone® series of devices, and HardCopy® II devices. These devices utilize a low-k dielectric material that dramatically reduces dynamic power and improves performance. Stratix III and Stratix II devices include new, more efficient, logic structures called adaptive logic modules (ALMs) that obtain maximum performance while minimizing power consumption. Cyclone III and Cyclone II devices offer the optimal blend of high performance and low power in a low-cost FPGA.

For more information about Stratix III architecture, refer to the *Stratix III Device Handbook*.

Altera provides the Quartus II PowerPlay Power Analyzer to aid you during the design process by delivering fast and accurate estimations of power consumption. You can minimize power consumption, while taking advantage of the industry's leading FPGA performance, by using the tools and techniques described in this chapter.

For more information about the PowerPlay Power Analyzer, refer to the *PowerPlay Power Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Total FPGA power consumption is comprised of I/O power, core static power, and core dynamic power. This chapter focuses on design optimization options and techniques that help reduce core dynamic power and I/O power. In addition to these techniques there are additional power optimization techniques available for Stratix III devices. These techniques include:

- Selectable Core Voltage
- Programmable Power Technology
- Device Speed Grade Selection

For more information about power optimization techniques available for Stratix III devices, refer to application note *AN: 437 Power Optimization in Stratix III FPGAs*.

## Power Dissipation

This section describes the sources of power dissipation in Stratix II and Cyclone II devices. You can refine techniques that reduce power consumption in your design by understanding the sources of power dissipation.

Figure 9-1 shows the power dissipation of Stratix II and Cyclone II devices in different designs. All designs were analyzed at a fixed clock rate of 200 MHz and exhibited varied logic resource utilization across available resources.

**Figure 9-1. Average Core Dynamic Power Dissipation**

**Notes to Figure 9-1:**

- (1) 112 different designs were used to obtain these results.
- (2) 93 different designs were used to obtain these results.
- (3) In designs using DSP blocks, DSPs consumed 5% of core dynamic power.

As shown in Figure 9-1, a significant amount of the total power is dissipated in routing for both Stratix II and Cyclone II devices, with the remaining power dissipated in logic, clock, and RAM blocks.

In Stratix and Cyclone device families, a series of column and row interconnect wires of varying lengths provide signal interconnections between logic array blocks (LABs), memory block structures, and digital signal processing (DSP) blocks or multiplier blocks. These interconnects dissipate the largest component of device power.

FPGA combinational logic is another source of power consumption. The basic building block of logic in Stratix III and Stratix II devices is the ALM, and in Cyclone III and Cyclone II devices, it is the logic element (LE).

For more information about ALMs and LEs in Stratix III, Stratix II, Cyclone III and Cyclone II devices, refer to the respective device handbook.

Memory and clock resources are other major consumers of power in FPGAs. Stratix II devices feature the TriMatrix memory architecture. TriMatrix memory includes 512-bit M512 blocks, 4-Kbit M4K blocks, and 512-Kbit M-RAM blocks, which are each configurable to support many features. Stratix III TriMatrix on-chip memory is an enhancement based upon the Stratix II FPGA TriMatrix memory and includes three sizes of memory blocks: MLAB blocks, M9K blocks, and M144K blocks. Cyclone II devices have 4-Kbit M4K memory blocks and Cyclone III devices have 9-Kbit M9K memory blocks.

## Design Space Explorer

The Design Space Explorer (DSE) is a simple, easy-to-use, design optimization utility that is included in the Quartus II software. The DSE explores and reports optimal Quartus II software options for your design, targeting either power optimization, design performance, or area utilization improvements. You can use the DSE to implement the techniques described in this chapter.

Figure 9–2 shows the DSE user interface. The **Settings** tab is divided into **Project Settings** and **Exploration Settings**.

**Figure 9–2. Design Space Explorer User Interface**

The **Search for Lowest Power** option, under **Exploration Settings**, uses a predefined exploration space that targets overall design power improvements. This setting focuses on applying different options that specifically reduce total design thermal power. You can also set the **Optimization Goal** option for your design using the **Advanced** tab in the DSE window. You can select your design optimization goal, such as optimize for power, from the list of available settings in the **Optimization Goal** list. The DSE then uses the selection from the **Optimization Goal** list, along with the **Search for Lowest Power** selection, to determine the best compilation results.

By default, the Quartus II PowerPlay Power Analyzer is run for every exploration performed by the DSE when the **Search for Lowest Power** option is selected. This helps you debug your design and determine trade-offs between power requirements and performance optimization.

For more information about the DSE, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*.

## Power-Driven Compilation

The standard Quartus II compilation flow consists of Analysis and Synthesis, Fitter, Assembler, and Timing Analysis. Power-driven compilation takes place at the analysis and synthesis and Fitter levels. Power-driven compilation settings are divided in the **PowerPlay power optimization** list on the **Analysis & Synthesis Settings** page, and **PowerPlay power optimization** on the **Fitter Settings** page. The following section describes these power optimization options at the analysis and synthesis and Fitter levels.

### *Power-Driven Synthesis*

Synthesis netlist optimization occurs during the synthesis stage of the compilation flow. The optimization technique makes changes to the synthesis netlist to optimize your design according to the selection of area, speed, or power optimization. This section describes power optimization techniques at the synthesis level.

The **Analysis & Synthesis Settings** page allows you to specify logic synthesis options. The **PowerPlay power optimization** option is available for the Arria GX, Stratix and Cyclone families of devices, and MAX<sup>®</sup> II devices (Figure 9–3).

To perform power optimization at the synthesis level in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Analysis & Synthesis**. The **Analysis & Synthesis** page appears.
3. In the **PowerPlay power optimization** list, select your preferred setting. This option determines how aggressively Analysis and Synthesis optimizes the design for power.

Figure 9–3. Analysis & Synthesis Settings Page

Table 9–1 shows the settings in the **PowerPlay power optimization** list. You can apply these settings on a project or entity level.

Settings	Description
Off	No netlist, placement, or routing optimizations are performed to minimize power
Normal compilation (Default)	Enables power optimizations as long as they are not expected to reduce design performance
Extra effort	Enables you to perform additional power optimizations which can reduce design performance

The **Normal compilation** setting is turned on by default. This setting performs memory optimization and power-aware logic mapping during synthesis.

Memory blocks can represent a large fraction of total design dynamic power as described in “[Reducing Memory Power Consumption](#)” on [page 9–23](#). Minimizing the number of memory blocks accessed during each clock cycle can significantly reduce memory power. Memory optimization involves effective movement of user-defined read/write enable signals to associated read-and-write clock enable signals for all memory types ([Figure 9–4](#)).

**Figure 9–4. Memory Transformation**

[Figure 9–4](#) shows a default implementation of a simple dual-port memory block in which write-clock enable and read-clock enable signals are connected to V<sub>CC</sub>, making both read-and-write memory ports active during each clock cycle. Memory transformation effectively moves the read-enable and write-enable signals to the respective read-clock enable and write-clock enable signals. By using this technique, memory ports are shut down when they are not accessed. This significantly reduces your design’s memory power consumption. For more information about clock enable signals, refer to “[Reducing Memory Power Consumption](#)” on [page 9–23](#). For Stratix III devices, the memory transformation takes place at the Fitter level by selecting the **Normal compilation** settings for the power optimization option.

In Stratix III and Cyclone III devices, the specified read-during-write behavior can significantly impact the power of single-port and bidirectional dual-port RAMs. It is best to set the read-during-write parameter to “Don’t care” (at the HDL level), as it allows an optimization whereby the read-enable signal can be set to the inversion of the existing write-enable signal (if one exists). This allows the core of the RAM to shut down (that is, not toggle), which saves a significant amount of power.

The other type of power optimization that takes place with the **Normal compilation** setting is power-aware logic mapping. The power-aware logic mapping reduces power by rearranging the logic during synthesis to eliminate nets with high toggle rates.

The **Extra effort** setting performs the functions of the **Normal compilation** setting and other memory optimizations to further reduce memory power by shutting down memory blocks that are not accessed. This level of memory optimization may require extra logic which can reduce design performance.

The **Extra effort** setting also performs power-aware memory balancing. Power-aware memory balancing automatically chooses the best memory configuration for your memory implementation and provides optimal power saving by determining the number of memory blocks, decoder, and multiplexer circuits needed. If you have not previously specified target-embedded memory blocks for your design’s memory functions, the power-aware balancer automatically selects them during memory implementation.

Figure 9–5 shows an example of a  $4\text{K} \times 4$  (4K deep and 4 bits wide) memory implementation in two different configurations using M4K memory blocks available in Stratix II devices. The minimum logic area implementation uses M4K blocks configured as  $4\text{K} \times 1$ . This implementation is the default in the Quartus II software because it has the minimum logic area (0 logic cells) and the highest speed. However, all four M4K blocks are active on each memory access in this implementation, which increases RAM power. The minimum RAM power implementation is created by selecting **Extra effort** in the **PowerPlay power optimization** list. This implementation automatically uses four M4K blocks configured as  $1\text{K} \times 4$  for optimal power saving. An address decoder is implemented by the altsyncram megafunction to select which of the four M4K blocks should be activated on a given cycle, based on the state of the top two user address bits. The altsyncram megafunction automatically implements a multiplexer to feed the downstream logic by choosing the appropriate M4K output. This

implementation reduces RAM power because only one M4K block is active on any cycle, but it requires extra logic cells, costing logic area and potentially impacting design performance.

There is a trade-off between power saved by accessing fewer memories and power consumed by the extra decoder and multiplexor logic. The Quartus II software automatically balances the power savings against the costs to choose the lowest power configuration for each logical RAM.

**Figure 9–5. 4K × 4 Memory Implementation Using Multiple M4K Blocks**

Memory optimization options can also be controlled by the `Low_Power_Mode` parameter in the **Default Parameters** page of the **Settings** dialog box. The settings for this parameter are **None**, **Auto**, and **ALL**. **None** corresponds to the **Off** setting in the **PowerPlay power optimization** list. **Auto** corresponds to the **Normal compilation** setting and **ALL** corresponds to the **Extra effort** setting, respectively. You can apply PowerPlay power optimization either on a compiler basis or on individual entities. The `Low_Power_Mode` parameter always takes precedence over the Optimize Power for Synthesis option for power optimization on memory.

You can also set the `MAXIMUM_DEPTH` parameter manually to configure the memory for low power optimization. This technique is the same as the power-aware memory balancer, but it is manual rather than automatic like the **Extra effort** setting in the **PowerPlay power optimization** list. You can set the `MAXIMUM_DEPTH` parameter for memory modules manually in the megafunction instantiation or in the MegaWizard® Plug-In Manager for power optimization as described in

“Reducing Memory Power Consumption” on page 9–23. The `MAXIMUM_DEPTH` parameter always takes precedence over the Optimize Power for Synthesis options for power optimization on memory optimization.

*Power-Driven Synthesis Experiment for Stratix II Devices*

In this experiment for Stratix II devices, three designs are compiled with the Quartus II software using **Normal compilation** and **Extra effort** settings in the **PowerPlay power optimization** list. The default setting for Fitter is **Normal compilation**. Table 9–2 shows resources used in the power-driven synthesis experiment.

**Table 9–2. Resources Used in the Power-Driven Synthesis Experiment for Stratix II Devices**

Design Name	Settings	ALUT	Register	Memory Bits
Design 1	Normal compilation	8,941	9,150	293,856
	Extra effort	8,954	9,151	293,856
Design 2	Normal compilation	28,169	12,148	1,009,920
	Extra effort	28,817	12,297	1,009,920
Design 3	Normal compilation	5,376	2,809	153,864
	Extra effort	5,559	2,813	153,864

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–6 shows that the power-driven synthesis reduces memory power consumption by as much as 68% in Stratix II devices.

**Figure 9–6. Memory Blocks Power Savings Using the Power-Driven Synthesis for Stratix II Devices**

## Power-Driven Fitter

The **Fitter Settings** page enables you to specify options for fitting (Figure 9-7). The **PowerPlay power optimization** option is available for Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II devices.

To perform power optimization at the Fitter level, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Fitter Settings**. The **Fitter Settings** page appears.
3. In the **PowerPlay power optimization** list, select your preferred setting. This option determines how aggressively the Fitter optimizes the design for power.

Figure 9–7. Fitter Settings Page

Table 9–3 lists the settings in the **PowerPlay power optimization** list. These settings can only be applied on a project-wide basis. The **Extra effort** setting for the Fitter requires extensive effort to optimize the design for power and can increase the compilation time.

<b>Settings</b>	<b>Description</b>
Off	No netlist, placement, or routing optimizations are performed to minimize power
Normal compilation (Default)	Enables power optimizations as long as they are not expected to reduce design performance
Extra effort	Enables you to perform additional power optimizations that can reduce design performance

The **Normal compilation** setting is selected by default and performs DSP optimization by creating power-efficient DSP block configurations for your DSP functions. For Stratix III devices, this setting, which is based on timing constraints entered for the design, enables the Programmable Power Technology to configure tiles as high-speed mode or low-power mode. Programmable Power Technology is always turned **ON** even when the **OFF** setting is selected for the Fitter PowerPlay power optimization option. Tiles are the combination of LAB and MLAB pairs (including the adjacent routing associated with LAB and MLAB) which can be configured to operate in high-speed or low-power mode. This level of power optimization will not have any affect on the fitting, timing results, or compile time. Also, for Stratix III devices, this setting enables the memory transformation as described in “[Power-Driven Synthesis](#)” on page 9–5.

For more information about Stratix III power optimization, refer to *AN 437: Power Optimization in Stratix III FPGAs*.

The **Extra effort** setting performs the functions of the **Normal compilation** setting and other place-and-route optimizations during fitting to fully optimize the design for power. The Fitter applies an extra effort to minimize power even after timing requirements have been met by effectively moving the logic closer during placement to localize high-toggling nets, and using routes with low capacitance. However, this effort can increase the compilation time.

The **Extra effort** setting uses a Signal Activity File (.saf) or Verilog Value Change Dump File (.vcd) that guides the Fitter to fully optimize the design for power based on the signal activity of the design. The best power optimization during fitting results from using the most accurate signal activity information. Signal activities from full post-fit netlist (timing) simulation provide the highest accuracy because all node activities reflect the actual design behavior, provided that supplied input vectors are representative of typical design operation. If you do not have a Signal Activity File (from simulation or other source), the Quartus II software uses assignments, clock assignments, and vectorless estimation values (PowerPlay Power Analyzer Tool settings) to estimate the signal activities. This information is used to optimize your design for power during fitting.

Only the **Extra effort** setting in the **PowerPlay power optimization** list for the Fitter option uses the signal activities (from Value Change Dump File or SAF) during fitting. The settings made in the **PowerPlay Power Analyzer Settings** page in the **Settings** dialog box are used to calculate the signal activity of your design.

For more information about Signal Activity Files and Verilog Value Change Dump Files, and how to create them, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

*Power-Driven Fitter Experiment for Stratix II Devices*

In this experiment for Stratix II devices, three designs are compiled with the Quartus II software using the **Normal compilation** and **Extra effort** settings in the Fitter for the PowerPlay power optimization list. The default setting for Analysis and Synthesis is **Normal compilation**.

Table 9-4 shows resources used in the power-driven Fitter experiment.

<i>Table 9-4. Designs Used in the Power-Driven Fitter Experiment for Stratix II Devices</i>		
<b>Design Name</b>	<b>ALUTs (Normal Compilation)</b>	<b>ALUTs (Extra Effort)</b>
Design 1	21,435	21,363
Design 2	19,035	18,970
Design 3	5,335	5,328

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9-8 shows that the power-driven Fitter technique reduces power consumption by as much as 19% in Stratix II devices.

**Figure 9-8. Power Savings Using the Power-Driven Fitter for Stratix II Devices**

## Recommended Flow for Power-Driven Compilation

Figure 9–9 shows the recommended design flow to fully optimize your design for power during compilation. This flow utilizes the power-driven synthesis and power-driven Fitter options. On average, you can reduce core dynamic power by 16% with the extra effort synthesis and extra effort fitting settings, as compared to off settings in both synthesis and Fitter options for power-driven compilation.

**Figure 9–9. Recommended Flow for Power-Driven Compilation**

### Area-Driven Synthesis

Using area optimization rather than timing or delay optimization during synthesis saves power because you use fewer logic blocks. Using less logic usually means less switching activity.

#### *Area-Driven Synthesis Experiment for Stratix II Devices*

In this experiment for Stratix II devices, five designs are compiled with the Quartus II software in two ways. First, the designs are compiled optimizing for area. The same designs are then compiled optimizing for speed. The power optimization settings for synthesis and fitting are set to **Off**.

Table 9-5 shows ALUT usage in the area-driven synthesis experiment.

Design Name	ALUTs (Area Mapping)	ALUTs (Speed Mapping)
Design 1	5,682	8,553
Design 2	16,986	17,783
Design 3	36,554	36,312
Design 4	4,717	5,820
Design 5	15,947	15,978

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9-10 shows that the area-driven technique reduces power consumption by as much as 31% in Stratix II devices.

**Figure 9-10. Power Savings Using Area-Driven Synthesis for Stratix II Devices**

#### *Area-Driven Synthesis Experiment for Cyclone II Devices*

In this experiment for Cyclone II devices, five designs are compiled with the Quartus II software in two ways. First, the designs are compiled optimizing for area. The same designs are then compiled optimizing for speed.

Table 9–6 shows LE usage in the area-driven synthesis experiment.

Design Name	LEs (Area Mapping)	LEs (Speed Mapping)
Design 1	13,020	16,429
Design 2	13,317	13,636
Design 3	5,384	5,690
Design 4	33,640	40,008
Design 5	21,409	22,988

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–11 shows that the area-driven technique reduces power consumption by as much as 15% in Cyclone II devices.

**Figure 9–11. Power Savings Using Area-Driven Synthesis for Cyclone III and Cyclone II Devices**

## Gate-Level Register Retiming

You can also use gate-level register retiming to reduce circuit switching activity. Retiming shuffles registers across combinational blocks without changing design functionality. The **Perform gate-level register retiming** option in the Quartus II software enables the movement of registers across combinational logic to balance timing, allowing the software to trade off the delay between timing critical and non-critical timing paths.

Retiming uses fewer registers than pipelining. Figure 9–12 shows an example of gate-level register retiming, where the 10 ns critical delay is reduced by moving the register relative to the combinational logic, resulting in the reduction of data depth and switching activity.

**Figure 9–12. Gate-Level Register Retiming**

Gate-level register retiming makes changes at the gate level. If you are using an atom netlist from a third-party synthesis tool, you must also select the **Perform WYSIWYG primitive resynthesis** option to undo the atom primitives to gates mapping (so that register retiming can be performed), and then to remap gates to Altera® primitives. When using the Quartus II integrated synthesis, retiming occurs during synthesis before the design is mapped to Altera primitives.

For more information about register retiming, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

### *Gate-Level Register Retiming Experiment for Stratix II Devices*

In this experiment for Stratix II devices, three designs are compiled with the Quartus II software in two ways. First, a netlist from a third-party synthesis tool is compiled. Then, the same netlist is compiled after selecting the **Perform WYSIWYG primitive resynthesis** and **Perform gate-level register retiming** options.

Table 9–7 shows resource usage results.

Design Name	WYSIWYG and Register Retiming	ALUTs	Registers	DSP Blocks	Memory
Design 1	No	2,051	691	0	16
	Yes	1,882	731	0	16
Design 2	No	123,909	40,070	0	0
	Yes	95,593	39,816	0	0
Design 3	No	6,354	6,019	64	3,584
	Yes	7,496	5,970	64	3,584

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–13 shows that the combination of WYSIWYG remapping and gate-level register retiming reduces power consumption by nearly 6% in Stratix II devices.

**Figure 9–13. Power Savings Using Retiming for Stratix II Devices**

#### *Gate-Level Register Retiming Experiment for Cyclone II Devices*

In this experiment for Cyclone II devices, three designs are compiled with the Quartus II software in two ways. First, a netlist from a third-party synthesis tool is compiled. Then, the same netlist is compiled by selecting the **Perform WYSIWYG primitive resynthesis** and **Perform gate-level register retiming** options.

Table 9-8 shows resource usage results.

Design Name	WYSIWYG and Register Retiming	LEs	Registers	Multiplier Blocks	Memory
Design 1	No	385	137	0	0
	Yes	278	143	0	0
Design 2	No	14,758	1,683	0	0
	Yes	13,079	1,683	0	0
Design 3	No	31,727	29,097	96	3,120
	Yes	27,038	24,272	96	3,120

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9-14 shows that the combination of WYSIWYG remapping and gate-level register retiming reduces power consumption by as much as 21% in Cyclone II devices.

**Figure 9-14. Power Savings Using Retiming for Cyclone II Devices**

## Design Guidelines

Several low-power design techniques can reduce power consumption when applied during FPGA design implementation. This section provides detailed design techniques for Stratix III, Stratix II, Cyclone III, and Cyclone II devices that affect overall design power. The results of these techniques may be different from design to design.

### Clock Power Management

Clocks represent a significant portion of dynamic power consumption due to their high switching activity and long paths. Figure 9-1 on page 9-2 shows a 7% average contribution to power consumption for global clock routing in Stratix II devices and 15% in Cyclone II devices. Actual clock-related power consumption is higher than this because the

power consumed by local clock distribution within logic, memory, and DSP or multiplier blocks is included in the power consumption for the respective blocks.

Clock routing power is automatically optimized by the Quartus II software, which only enables those portions of the clock network that are required to feed downstream registers. Power can be further reduced by gating clocks when they are not needed. It is possible to build clock gating logic, but this approach is not recommended because it is difficult to generate a glitch-free clock in FPGAs using ALMs or LEs.

Arria GX, Stratix III, Stratix II, Cyclone III, and Cyclone II devices use clock control blocks that include an enable signal. A clock control block is a clock buffer that lets you dynamically enable or disable the clock network and dynamically switch between multiple sources to drive the clock network. You can use the Quartus II MegaWizard Plug-In Manager to create this clock control block with the `altclkctrl` megafunction. Arria GX, Stratix III, Stratix II, Cyclone III, and Cyclone II devices provide clock control blocks for global clock networks. In addition, Stratix III and Stratix II devices have clock control blocks for regional clock networks. The dynamic clock enable feature lets internal logic control the clock network. When a clock network is powered down, all the logic fed by that clock network does not toggle, thereby reducing the overall power consumption of the device. Figure 9–15 shows a 4-input clock control block diagram.

**Figure 9–15. Clock Control Block Diagram**

The enable signal is applied to the clock signal before being distributed to global routing. Therefore, the enable signal can either have a significant timing slack (at least as large as the global routing delay) or it can reduce the  $f_{MAX}$  of the clock signal.

For more information about using clock control blocks, refer to the *altclkctrl Megafunction User Guide*.

Another contributor to clock power consumption is the LAB clock that distributes a clock to the registers within a LAB. LAB clock power can be the dominant contributor to overall clock power. For example, in Cyclone III and Cyclone II devices, each LAB can use two clocks and two clock enable signals, as shown in Figure 9-16. Each LAB's clock signal and clock enable signal are linked. For example, an LE in a particular LAB using the `labclk1` signal also uses the `labclkena1` signal.

**Figure 9-16. LAB-Wide Control Signals**

To reduce LAB-wide clock power consumption without disabling the entire clock tree, use the LAB-wide clock enable to gate the LAB-wide clock. The Quartus II software automatically promotes register-level clock enable signals to the LAB-level. All registers within an LAB that share a common clock and clock enable are controlled by a shared gated clock. To take advantage of these clock enables, use a clock enable construct in the relevant HDL code for the registered logic.

### *LAB-Wide Clock Enable Example*

This VHDL code makes use of a LAB-wide clock enable. This clock-gating logic is automatically turned into an LAB-level clock enable signal.

```

IF clk'event AND clock = '1' THEN
    IF logic_is_enabled = '1' THEN
        reg <= value;
    ELSE

```

```

        reg <= reg;
    END IF;
END IF;

```

For more information about LAB-wide control signals, refer to the *Stratix II Architecture*, *Cyclone III Architecture*, or *Cyclone II Architecture* chapters in the respective device handbook.

## Reducing Memory Power Consumption

The memory blocks in FPGA devices can represent a large fraction of typical core dynamic power. Memory represents 14% of the core dynamic power in a typical Stratix II device design and 9% in a Cyclone II device design. Memory blocks are unlike most other blocks in the device because most of their power is tied to the clock rate, and is insensitive to the toggle rate on the data and address lines.

When a memory block is clocked, there is a sequence of timed events that occur within the block to execute a read or write. The circuitry controlled by the clock consumes the same amount of power regardless of whether or not the address or data has changed from one cycle to the next. Thus, the toggle rate of input data and the address bus have no impact on memory power consumption.

The key to reducing memory power consumption is to reduce the number of memory clocking events. You can achieve this through clock network-wide gating described in [“Clock Power Management” on page 9–20](#), or on a per-memory basis through use of the clock enable signals on the memory ports. [Figure 9–17](#) shows the logical view of the internal clock of the memory block. Use the appropriate enable signals on the memory to make use of the clock enable signal instead of gating the clock.

**Figure 9–17. Memory Clock Enable Signal**

Using the clock enable signal enables the memory only when necessary and shuts it down for the rest of the time, reducing the overall memory power consumption. You can use the Quartus II MegaWizard Plug-In Manager to create these enable signals by selecting the **Clock enable signal** option for the appropriate port when generating the memory block function ([Figure 9–18](#)).

**Figure 9–18. MegaWizard Plug-In Manager RAM 2-Port Clock Enable Signal Selectable Option**

For example, consider a design that contains a 32-bit-wide M4K memory block in ROM mode that is running at 200 MHz. Assuming that the output of this block is only needed approximately every four cycles, this memory block will consume 8.45 mW of dynamic power according to the demands of the downstream logic. By adding a small amount of control logic to generate a read clock enable signal for the memory block only on the relevant cycles, the power can be cut 75% to 2.15 mW.

You can also use the `MAXIMUM_DEPTH` parameter in your memory megafunction to save power in Stratix III, Stratix II, Cyclone III, and Cyclone II devices; however, this approach may increase the number of LEs required to implement the memory and affect design performance.

You can set the `MAXIMUM_DEPTH` parameter for memory modules manually in the megafunction instantiation or in the MegaWizard Plug-In Manager (Figure 9–19). The Quartus II software automatically chooses the best design memory configuration for optimal power as, described in “Power-Driven Compilation” on page 9–5.

**Figure 9–19. MegaWizard Plug-In Manager RAM 2-Port Maximum Depth Selectable Option**

### Memory Power Reduction Example

Table 9–9 shows power usage measurements for a  $4K \times 36$  simple dual-port memory implemented using multiple M4K blocks in a Stratix II EP2S15 device. For each implementation, the M4K blocks are configured with a different memory depth.

**Table 9–9.  $4K \times 36$  Simple Dual-Port Memory Implemented Using Multiple M4K Blocks**

M4K Configuration	Number of M4K Blocks	ALUTs
$4K \times 1$ (Default setting)	36	0
$2K \times 2$	36	40
$1K \times 4$	36	62
$512 \times 9$	32	143
$256 \times 18$	32	302
$128 \times 36$	32	633

Figure 9–20 shows the amount of power saved using the `MAXIMUM_DEPTH` parameter. For all implementations, a user-provided read enable signal is present to indicate when read data is needed. Using this power-saving technique can reduce power consumption by as much as 60%.

**Figure 9–20. Power Savings Using the `MAXIMUM_DEPTH` Parameter**

As the memory depth becomes more shallow, memory dynamic power decreases because unaddressed M4K blocks can be shut off using a decoded combination of address bits and the read enable signal. For a 128-deep memory block, power used by the extra LEs starts to outweigh the power gain achieved by using a more shallow memory block depth. The power consumption of the memory blocks and associated LEs depends on the memory configuration.

## Pipelining and Retiming

Designs with many glitches consume more power because of faster switching activity. Glitches cause unnecessary and unpredictable temporary logic switches at the output of combinational logic. A glitch usually occurs when there is a mismatch in input signal timing leading to unequal propagation delay.

For example, consider an input change on one input of a 2-input XOR gate from 1 to 0, followed a few moments later by an input change from 0 to 1 on the other input. For a moment, both inputs become 1 (high) during the state transition, resulting in 0 (low) at the output of the XOR gate. Subsequently, when the second input transition takes place, the XOR gate output becomes 1 (high). During signal transition, a glitch is produced before the output becomes stable, as shown in Figure 9–21. This glitch can propagate to subsequent logic and create unnecessary switching activity, increasing power consumption. Circuits with many XOR functions, such as arithmetic circuits or cyclic redundancy check (CRC) circuits, tend to have many glitches if there are several levels of combinational logic between registers.

**Figure 9–21. XOR Gate Showing Glitch at the Output**

Pipelining can reduce design glitches by inserting flip-flops into long combinational paths. Flip-flops do not allow glitches to propagate through combinational paths. Therefore, a pipelined circuit tends to have less glitching. Pipelining has the additional benefit of generally allowing higher clock speed operations, although it does increase the latency of a circuit (in terms of the number of clock cycles to a first result). [Figure 9–22](#) shows an example where pipelining is applied to break up a long combinational path.

**Figure 9–22. Pipelining Example**

Pipelining is very effective for glitch-prone arithmetic systems because it reduces switching activity, resulting in reduced power dissipation in combinational logic. Additionally, pipelining allows higher-speed

operation by reducing logic-level numbers between registers. The disadvantage of this technique is that if there are not many glitches in your design, pipelining may increase power consumption by adding unnecessary registers. Pipelining can also increase resource utilization.

*Pipelining Experiment for Stratix II Devices*

In this experiment, three designs are implemented in Stratix II devices with and without pipelining. These three designs use arithmetic heavily (based on XOR functions) and may result in significant glitching.

Table 9–10 shows the resource utilization for the designs used in the experiment.

Design Name	Pipelined	ALUTs	Registers
Multiplier (Design 1)	No	9,726	448
	Yes	9,772	1,109
Accumulator multipliers (Design 2)	No	13,719	1,120
	Yes	14,007	2,260
Fir filter (Design 3)	Yes (level 1)	1,048	949
	Yes (level 2)	932	929

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–23 shows that pipelining reduces dynamic power consumption by as much as 31% in Stratix II devices.

**Figure 9–23. Power Savings Using Pipelining for Stratix II Devices**

### Pipelining Experiment for Cyclone II Devices

In this experiment, three designs are implemented in Cyclone II devices with and without pipelining. These three designs use arithmetic heavily (based on XOR functions) and may result in significant glitching.

Table 9–11 shows resource utilization for the designs used in the experiment.

Design Name	Pipelined	LEs	Registers
Accumulator Multipliers (Design 1)	No	6,870	320
	Yes	13,071	3,719
Adder (Design 2)	No	7,392	1,076
	Yes	7,343	752
Divider (Design 3)	No	6,659	320
	Yes	6,735	520

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–24 shows that pipelining reduces dynamic power by as much as 31% in Cyclone II devices.

**Figure 9–24. Power Savings Using Pipelining for Cyclone II Devices**

### Architectural Optimization

You can use design-level architectural optimization by taking advantage of specific device architecture features. These features include dedicated memory and DSP or multiplier blocks available in FPGA devices to perform memory or arithmetic-related functions. You can use these

blocks in place of LUTs to reduce power consumption. For example, you can build large shift registers from RAM-based FIFO buffers instead of building the shift registers from the LE registers.

The Stratix device family allows you to efficiently target small, medium, and large memories with the TriMatrix memory architecture. Each TriMatrix memory block is optimized for a specific function. The M512 memory blocks available in Stratix II devices are useful for implementing small FIFO buffers, DSP, and clock domain transfer applications. M512 memory blocks are more power-efficient than the distributed memory structures in some competing FPGAs. The M4K memory blocks are used to implement buffers for a wide variety of applications, including processor code storage, large look-up table implementation, and large memory applications. The M-RAM blocks are useful in applications where a large volume of data must be stored on-chip. Effective utilization of these memory blocks can have a significant impact on power reduction in your design.

The Cyclone device family has configurable M4K and M9K memory blocks that provide various memory functions such as RAM, FIFO buffers, and ROM.

For more information about using DSP and memory blocks efficiently, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

### *Architectural Optimization Experiment for Stratix II Devices*

In this experiment, three designs are implemented in Stratix II devices in three ways to illustrate the power-reducing capabilities of dedicated blocks. The first two designs use logic elements and DSP blocks. The third design uses M4K and M-RAM blocks. In the third design, you can see that using MRAM blocks is more power efficient than using M4K blocks for large memory applications. The power optimization options for synthesis and fitting are turned off in this experiment.

Table 9–12 shows relative resource usage results.

<b>Design Name</b>	<b>Implementation</b>	<b>ALUT</b>	<b>Register</b>	<b>DSP Blocks</b>	<b>Memory</b>
Design 1	Regular implementation	9,726	448	0	0
	Dedicated resource implementation	1,124	448	121	0

**Table 9–12. Designs Used in the Architectural Optimization Experiment for Stratix II Devices (Part 2 of 2)**

Design Name	Implementation	ALUT	Register	DSP Blocks	Memory
Design 2	Regular implementation	13,719	1,120	0	0
	Dedicated resource implementation	2,880	896	212	0
Design 3	M4K	286	228	0	1,835,008 (M4K)
	M-RAM	224	224	0	1,835,008 (M-RAM)

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. [Figure 9–25](#) shows that the architectural optimization technique has power savings of over 60% in Stratix II devices.

**Figure 9–25. Power Savings Using Dedicated Blocks for Stratix II Devices**

### *Architectural Optimization Experiment for Cyclone II*

In this experiment, three designs are implemented in Cyclone II devices in three ways to illustrate the power-reducing capabilities of dedicated blocks. The first two designs use LEs and multiplier blocks. The third design uses LEs and M4K blocks.

Table 9–13 shows relative resource usage results.

Design Name	Implementation	LEs	Register	Multiplier Blocks	Memory
Design 1	Regular implementation	6,870	320	0	0
	Dedicated resource implementation	1,130	320	49	0
Design 2	Regular implementation	7,343	752	0	0
	Dedicated resource implementation	1,401	608	44	0
Design 3	Regular implementation	1,550	1,265	0	0
	M4K	72	72	0	1,152

The PowerPlay Power Analyzer estimates the power using a gate-level simulation output file. Figure 9–26 shows that the architectural optimization technique has power savings of as much as 88% in Cyclone II devices.

**Figure 9–26. Power Savings Using Dedicated Blocks for Cyclone II Devices**

## I/O Power Guidelines

Non-terminated I/O standards such as LVTTTL and LVCMOS have a rail-to-rail output swing. The voltage difference between logic-high and logic-low signals at the output pin is equal to the  $V_{CCIO}$  supply voltage. If the capacitive loading at the output pin is known, the dynamic power consumed in the I/O buffer can be calculated as:

$$P = 0.5 \times F \times C \times V^2$$

In this equation,  $F$  is the output transition frequency and  $C$  is the total load capacitance being switched.  $V$  is equal to  $V_{CCIO}$  supply voltage. Because of the quadratic dependence on  $V_{CCIO}$ , lower voltage standards consume significantly less dynamic power. In addition, lower pin capacitance is an important factor in considering I/O power consumption. Hardware and simulation data show that Stratix II device I/O pins have half the pin capacitance of the nearest competing FPGA. Cyclone II devices exhibit 20% less I/O power consumption than competitive, low-cost, 90 nm FPGAs.

Transistor-to-transistor logic (TTL) I/O buffers consume very little static power. As a result, the total power consumed by a LVTTTL or LVCMOS output is highly dependent on load and switching frequency.

When using resistively terminated I/O standards like SSTL and HSTL, the output load voltage swings by a small amount around some bias point. The same dynamic power equation is used, where  $V$  is the actual load voltage swing. Because this is much smaller than  $V_{CCIO}$ , dynamic power is lower than for non-terminated I/O under similar conditions. These resistively terminated I/O standards dissipate significant static (frequency-independent) power, because the I/O buffer is constantly driving current into the resistive termination network. However, the lower dynamic power of these I/O standards means they often have lower total power than LVCMOS or LVTTTL for high-frequency applications. Use the lowest drive strength I/O setting that meets your speed and waveform requirements to minimize I/O power when using resistively terminated standards.

You can save a small amount of static power by connecting unused I/O banks to the lowest possible  $V_{CCIO}$  voltage of 1.2 V.

Table 9–14 shows the total supply and thermal power consumed by outputs using different I/O standards for Stratix II devices. The numbers are for an I/O pin transmitting random data clocked at 200 MHz with a 10 pF capacitive load.

<b>Standard</b>	<b>Total Supply Current Drawn from V<sub>CCIO</sub> Supply (mA)</b>	<b>Total On-Chip Thermal Power Dissipation (mW)</b>
3.3-V LVTTTL	2.42	9.87
2.5-V LVCMOS	1.9	6.69
1.8-V LVCMOS	1.34	4.18
1.5-V LVCMOS	1.18	3.58
3.3-V PCI	2.47	10.23
SSTL-2 class I	6.07	4.42
SSTL-2 class II	10.72	5.1
SSTL-18 class I	5.33	3.28
SSTL-18 class II	8.56	4.06
HSTL-15 class I	6.06	3.49
HSTL-15 class II	11.08	4.87
HSTL-18 class I	6.87	4.09
HSTL-18 class II	12.33	5.82

For this configuration, non-terminated standards generally use less power, but this is not always the case. If the frequency or the capacitive load is increased, the power consumed by non-terminated outputs increases faster than the power of terminated outputs.

For more information about I/O Standards, refer to the *Selectable I/O Standards in Stratix II Devices and Stratix II GX Devices* chapter in volume 2 of the *Stratix II Device Handbook* or the *Selectable I/O Standards in Cyclone II Devices* chapter in the *Cyclone II Device Handbook* or the *Cyclone III Device Handbook*.

When calculating I/O power, the PowerPlay Power Analyzer uses the default capacitive load set for the I/O standard in the **Capacitive Loading** tab of the **Device & Pin Options** dialog box. If **Enable Advanced I/O Timing** is turned on, I/O power is measured using an equivalent load calculated as the sum of the near capacitance, the transmission line distributed capacitance, and the far end capacitance as defined in the **Board Trace Model** tab of the **Device & Pin Options** dialog box or the

Board Trace Model view in the Pin Planner. Any other components defined in the board trace model are not taken into account for the power measurement.

For information about using Advanced I/O Timing and configuring a board trace model, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

## Power Optimization Advisor

The Quartus II software includes the Power Optimization Advisor, which provides specific power optimization advice and recommendations based on the current design project settings and assignments. The advisor covers many of the suggestions listed in this chapter. The following example shows how to reduce your design power with the Power Optimization Advisor.

### *Power Optimization Advisor Example*

After compiling your design, run the PowerPlay Power Analyzer to determine your design power and to see where power is dissipated in your design. Based on this information, you can run the Power Optimization Advisor to implement recommendations that can reduce design power. [Figure 9-27](#) shows the Power Optimization Advisor after compiling a design that is not fully optimized for power.

Figure 9–27. Power Optimization Advisor

Power-Driven Synthesis	
Recommendation	Set PowerPlay Power Optimization during synthesis to Extra Effort.
Description	Extra effort power-driven synthesis will choose logic and RAM implementations which minimize design dynamic power. <a href="#">More Info</a>
Summary	The following areas will be affected by the recommended changes: <ul style="list-style-type: none"> <li>• Delay may increase (fmax may decrease)</li> <li>• Logic element usage may increase</li> <li>= Compilation time is unaffected</li> </ul>
Action	Set PowerPlay Power Optimization during synthesis to Extra Effort  No action is needed for this recommendation. The recommended setting has been made.  Current Global Settings: PowerPlay Power Optimization = EXTRA EFFORT (Recommended: EXTRA EFFORT)  <a href="#">Correct the Settings</a>  <a href="#">Open Settings dialog box - Analysis &amp; Synthesis Settings page</a>

The Power Optimization Advisor shows the recommendations that can reduce power in your design. The recommendations are split into stages to show the order in which you should apply the recommended settings. The first stage shows the mostly CAS settings options that are easy to implement and highly effective in reducing design power. An icon indicates whether each recommended setting is made in the current project. In Figure 9–27, the checkmark icon for Stage 1 shows the recommendations that are already implemented. The warning icons indicate recommendations that are not followed for this compilation. The information icon shows the general suggestions. Each recommendation includes the description, summary of the affect of the recommendation, and the action required to make the appropriate setting.

There is a link from each recommendation to the appropriate location in the Quartus II user interface where you can change the setting, such as the **Power-Driven Synthesis** setting. You can change the **Power-Driven Synthesis** setting by clicking **Open Settings dialog box - Analysis & Synthesis Settings page** (Figure 9–28). The **Settings** dialog box is shown with the **Analysis & Synthesis Settings** page selected, where you can change the **PowerPlay power optimization** settings.

Figure 9–28. Analysis &amp; Synthesis Settings Page

After making the recommended changes, recompile your design. The Power Optimization Advisor indicates with green checkmarks that the recommendations were implemented successfully (Figure 9–29). You can use the PowerPlay Power Analyzer to verify your design power results.

**Figure 9–29. Implementation of Power Optimization Advisor Recommendations**

The recommendations listed in Stage 2 generally involve design changes, rather than CAD settings changes as in Stage 1. You can use these recommendations to further reduce your design power consumption. Altera recommends that you implement Stage 1 recommendations first, then the Stage 2 recommendations.

## Conclusion

The combination of a smaller process technology, the use of low-k dielectric material, and reduced supply voltage significantly reduces dynamic power consumption in the latest FPGAs. To further reduce your dynamic power, you should use the design recommendations presented in this chapter to optimize resource utilization and minimize power consumption.

## Document Revision History

Table 9–15 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized "Referenced Documents" on page 9–39.	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>• Updated Power Dissipation.</li> <li>• Updated Power-Driven Compilation.</li> <li>• Added Referenced Documents.</li> </ul>	Updated figures for the Quartus II software 7.1. Added support for Arria GX.
March 2007 v7.0.0	Minor text edits to include Cyclone III information; added new screenshot to Figure 9-2.	Added support information for the Cyclone III device.
November 2006 v6.1.0	Updated figures to accommodate GUI changes in the software	Added information about Stratix III support. Changes in procedures were made for Quartus II enhancements to new user functionality.
May 2006 v6.0.0	Updated for the Quartus II software version 6.0.0: Updated device support Added multi-VCD/SAF support information Updated achieved power reductions values	—
October 2005 v5.1.0	Chapter 9 was formerly Chapter 7 in Volume 1: Stratix II Low Power Design Techniques.	—

## Introduction

As FPGA designs grow larger and larger in density, the need to analyze the design for performance, routing congestion, and logic placement to meet the design requirements becomes critical.

You can use the Chip Planner as a powerful tool to perform design analysis and create a design floorplan. With some of the older device families, you must use the Timing Closure Floorplan tool to analyze the device floorplan.

This chapter discusses how to analyze the design floorplan with both the Chip Planner and the Timing Closure Floorplan tools. It also shows you how to create LogicLock™ regions in the design floorplan and how to use the LogicLock design methodology as a performance preservation tool for older device families.

This chapter includes the following topics:

- “Chip Planner Overview” on page 10–2
- “LogicLock Regions” on page 10–6
- “Using LogicLock Regions in the Chip Planner” on page 10–11
- “Design Analysis Using the Chip Planner” on page 10–13
- “Timing Closure Floorplan Overview” on page 10–36
- “Design Analysis Using the Timing Closure Floorplan” on page 10–38
- “Using LogicLock Methodology for Older Device Families” on page 10–57
- “Scripting Support” on page 10–67

To view and create assignments for a design floorplan in supported devices, use the Chip Planner. To make I/O assignments, you must use the Pin Planner tool.

For more information about the Pin Planner tool, refer to the *Early I/O Planning Using the Pin Planner* section of the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

Table 10–1 lists the device families supported by the Chip Planner and the Timing Closure Floorplan.

<b>Device Family</b>	<b>Timing Closure Floorplan</b>	<b>Chip Planner</b>
Arria™ GX	—	✓
Stratix® III	—	✓
Stratix II	—	✓
Stratix II GX	—	✓
Stratix	—	✓

This chapter describes how to use the Chip Planner—and the Timing Closure Floorplan for devices not supported by the Chip Planner—for design analysis.

## Chip Planner Overview

The Chip Planner provides a visual display of chip resources. It can show logic placement, LogicLock and custom regions, relative resource usage, detailed routing information, fan-in and fan-out paths between registers, and delay estimates for paths. With the Chip Planner, you can view critical path information, physical timing estimates, and routing congestion.

The Chip Planner can perform assignment changes, such as creating and deleting resource assignments, as well as post-compilation changes, such as creating, moving, and deleting logic cells and I/O atoms. By using the

Chip Planner in conjunction with the Resource Property Editor, you can change connections between resources and make post-compilation changes to the properties of logic cells, I/O elements, PLLs, and RAM and DSP blocks. With the Chip Planner, you can view and create assignments for a design floorplan, perform power and design analyses, and implement ECOs in a single tool.

For details about how to implement ECOs in your design using the Chip Planner tool, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

## Starting Chip Planner

To start the Chip Planner, on the Tools menu, click **Chip Planner (Floorplan & Chip Editor)**. Other methods to start the Chip Planner include:

- Click the Chip Planner icon on the Quartus II software toolbar
- Use the shortcut menu from the following sources and use the Locate menu:
  - Compilation Report
  - Project Navigator window
  - RTL source code
  - Node Finder
  - Simulation Report
  - RTL Viewer

If the device in your project is not supported by the Chip Planner and you attempt to start the Chip Planner, the following message appears: Can't display Chip Planner: the current device family is unsupported. Use the Timing Closure Floorplan for these devices.

## Chip Planner Toolbar

The Chip Planner gives you powerful capabilities for design analysis with a very user-friendly GUI. Many functions within the Chip Planner can be selected or performed from the menu items or by clicking the icons on the toolbar. [Figure 10-1](#) shows an example of the Chip Planner Toolbar and provides descriptions for commonly used icons available from the Chip Planner toolbar.

Figure 10–1. Chip Planner Toolbar

You can customize the icons present on the Chip Planner's toolbar by clicking **Customize Chip Planner** on the Tools menu (if the Chip Planner window is attached) or by clicking **Customize** on the Tools menu (if the Chip Planner window is detached).

## Chip Planner Tasks and Layers

The Chip Planner has predefined tasks that enable you to quickly implement ECO changes or manipulate assignments for the floorplan of the device. To select a task, click on it in the Task pull-down menu. The predefined tasks in the Chip Planner are:

- Floorplan Editing (Assignment)
- Post-Compilation Editing (ECO)
- Partition Display (Assignment)

- Global Clock Network (Assignment)
- Power Analysis (Assignment) — available for Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, and HardCopy II devices only

In the Chip Planner, layers allow you to specify the graphic elements that are displayed for a given task. You can turn off the display of specific graphic elements to increase the window refresh speed and reduce visual clutter when viewing complex designs. The Background Color Map indicates the relative level of resource usage for different areas of the device. For example, Routing Utilization indicates the relative routing utilization, and Physical Timing Estimate indicates the relative physical timing.

Each predefined task in the Chip Planner has a Background Color Map, a set of displayed layers, and an editing mode associated with it. Click the **Layers** icon (shown in [Figure 10-1](#)) to display the Layers Settings window ([Figure 10-2](#)). In this window you can select the layers and background color map for each task.

**Figure 10-2. Layers in the Chip Planner**

The Chip Planner operates in either **Assignment** or **ECO** mode. You can use either of these modes to perform design analyses. Use the Floorplan Editor (Assignment) task in the Assignment mode to manipulate LogicLock regions and location assignments in your design. The Post Compilation Changes (ECO) task in ECO mode allows you to implement ECO changes in your design. The Partition Display (Assignment) task allows you to view the placement of nodes and color-codes the nodes based on their partition. When you select the Global Clock Network (Assignment) task, you can see all the global clock regions in your device. The Power Analysis (Assignment) task allows you to view high and low power resources in a Stratix III device.

For more information about the ECO mode of operation, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

You can also create and save your own custom tasks. When you create a custom task, you can turn on or off any layer in your task. Layers can be turned on or off by checking the appropriate box located next to each layer. You can also select different Background Color Maps to be used for your custom task. After selecting the required settings, you can click **Save Task As** to save your custom task.

## LogicLock Regions

LogicLock regions are user-defined rectangular regions within the device. You can use LogicLock regions to create a floorplan for your design. Your floorplan may contain several non-overlapping LogicLock regions. A LogicLock region is defined by its size (height and width) and location (where the region is located on the device). You can specify the size or location of a region, or both, or the Quartus® II software can generate these properties automatically. The Quartus II software bases the size and location of a region on the region's contents and the module's timing requirements. [Table 10-2](#) describes the options for creating LogicLock regions.

**Table 10-2. Types of LogicLock Regions (Part 1 of 2)**

Properties	Values	Behavior
State	Floating (default), Locked	Floating regions allow the Quartus II software to determine the region's location on the device. Locked regions represent user-defined locations for a region and are shown with a solid boundary in the floorplan. A locked region must have a fixed size.
Size	Auto (default), Fixed	Auto-sized regions allow the Quartus II software to determine the appropriate size of a region given its contents. Fixed regions have a user-defined shape and size.

## Placing LogicLock Regions

A fixed region must contain all resources required for the module. Although the Quartus II software can automatically place and size LogicLock regions to meet resource and timing requirements, you can manually place and size regions to meet your design needs. To do so, follow these guidelines:

- LogicLock regions with pin assignments must be placed on the periphery of the device, adjacent to the pins. (For Stratix and Cyclone series of devices and MAX II devices, you must also include the I/O block).
- Floating LogicLock regions cannot overlap.
- Avoid creating fixed and locked regions that overlap.

If you want to import multiple instances of a module into a top-level design, you must ensure that the device has two or more locations with exactly the same device resources. If the device does not have another area with exactly the same resources, the Quartus II software generates a fitting error during compilation of the top-level design.

## Placing Device Features into LogicLock Regions

A LogicLock region includes all device resources within its boundaries, including memory and pins. You can assign pins to LogicLock regions; however, this placement puts location constraints on the region. When the Quartus II software places a floating auto-sized region, it places the region in an area that meets the requirements of the LogicLock region's contents.

Pin assignments to LogicLock regions are effective only in fixed and locked regions. Pins assigned to floating regions do not influence the region's placement.

Only one LogicLock region can claim a device resource. If the boundary includes part of a device resource, the Quartus II software allocates the entire resource to the LogicLock region.

## LogicLock Regions Window

The LogicLock window consists of the LogicLock Regions window (Figure 10-4) and the **LogicLock Region Properties** dialog box. Use the LogicLock Regions window to create LogicLock regions and assign nodes and entities to them. The dialog box provides a summary of all LogicLock regions in your design. In the LogicLock Regions window, you can modify a LogicLock region's size, state, width, height, and origin as well

as whether the region is soft or reserved. When the region is back-annotated, the placement of each node within the region is relative to the region's origin, and the region's node placements are maintained during subsequent compilations.

The origin location varies based on device family. For Arria GX devices, Stratix and Cyclone series devices, and MAX II devices, the LogicLock region's origin is located at the lower left corner of the region. For all other supported devices, the origin is located at the upper left corner of the region.

**Figure 10–4. LogicLock Regions Window**

Region Name	Size	Width	Height	State	Origin	Reserved	
LogicLock Regions							
[-] Root Region	Fixed	34	26	Locked	LAB_1_A1	Off	
[-] <<new>>							
[-] usb1_ctr:u4	Fixed	7	6	Locked	LAB_8_A1	Off	
[-] usb1_idma:u2	Fixed	3	3	Floating	Floating	Off	
[-] usb1_pe:u3	Fixed	4	4	Floating	Floating	Off	

You can customize the LogicLock Regions window by dragging and dropping the various columns. Columns can also be hidden.

The **Soft** and **Reserved** columns are not shown by default.

For designs targeting Stratix and Cyclone series and MAX II devices, the Quartus II software automatically creates a LogicLock region that encompasses the entire device. This default region is labelled `Root_region`, and it is effectively locked and fixed.

Use the **LogicLock Region Properties** dialog box to obtain detailed information about your LogicLock region, such as which entities and nodes are assigned to your region and what resources are required. The **LogicLock Region Properties** dialog box shows the properties of the current selected regions.

To open the **LogicLock Region Properties** dialog box, double-click any region in the LogicLock Regions window, or right-click the region and click **Properties**.

## Excluded Resources

The Excluded Resources feature allows you to easily exclude specific device resources such as DSP blocks or M4K memory blocks from a LogicLock region. For example, you can specify resources that belong to a specific entity that are assigned to a LogicLock region, and specify that these resources be included with the exception of the DSP blocks. Use the Excluded Resources feature on a per-LogicLock region member basis.

To exclude certain device resources from an entity, in the **LogicLock Region Properties** dialog box, highlight the entity in the **Design Element** column, and click **Edit**. In the **Edit Node** dialog box, under **Excluded Element Types**, click on (...). In the **Excluded Resources Element Types** dialog box, you can select the device resources you want to exclude from the entity. Once you have selected the resources to exclude, the **Excluded Resources** column is updated in the **LogicLock Region Properties** dialog box to reflect the excluded resources.

The Excluded Resources feature prevents certain resource types from being included in a region, but it does not prevent the resources from being placed inside the region unless the region's "Reserved" property is set to **On**. To inform the Fitter that certain resources are not required inside a LogicLock region, define a resource filter.

## Hierarchical (Parent and Child) LogicLock Regions

You can define a hierarchy for a group of regions by declaring parent and child regions. The Quartus II software places a child region completely within the boundaries of its parent region, allowing you to further constrain module locations. Additionally, parent and child regions allow you to further improve a module's performance by constraining the nodes in the module's critical path.

To make one LogicLock region a child of another LogicLock region, in the LogicLock Regions window, select the new child region and drag and drop it in its new parent region.

The LogicLock region hierarchy does not have to be the same as the design hierarchy.

A child region's location can float within its parent or remain locked relative to its parent's origin. A locked parent region's location is locked relative to the device. If the child's location is locked and the parent's location is changed, the child's origin changes but maintains the same

placement relative to the origin of its parent. Either you or the Quartus II software can determine a child region's size; however, the child region must fit entirely within the parent region.

## Using LogicLock Regions in the Chip Planner

### Assigning LogicLock Region Content

Once you have defined a LogicLock region, you must assign resources to it using the Chip Planner, the **LogicLock Regions** dialog box, or a Tcl script.

You can drag selected logic displayed in the **Hierarchy** tab of the **Project Navigator**, in the Node Finder, or in a schematic design file, and drop it into the Chip Planner or the **LogicLock Regions** dialog box. [Figure 10–5](#) shows logic that has been dragged from the **Hierarchy** tab of the **Project Navigator** and dropped into a LogicLock region in the **Chip Planner**.

**Figure 10–5. Drag and Drop Logic in the Chip Planner**

You can also drag logic from the **Hierarchy** tab of the **Project Navigator** and drop it in the **LogicLock Regions Properties** dialog box. Logic can also be dropped into the **Design Element Assigned** column of the **Contents** tab of the **LogicLock Region Properties** box.

You must assign pins to a LogicLock region manually. The Quartus II software does not include pins automatically when you assign an entity to a region. The software only obeys pin assignments to locked regions that border the periphery of the device. For the Stratix and Cyclone series of devices and MAX II devices, the locked regions must include the I/O pins as resources.

## Creating LogicLock Regions with the Chip Planner

This section explains the basics of creating LogicLock regions. You can use the following methods to create a LogicLock region in the Chip Planner:

- On the Assignments menu, click **LogicLock Regions Window**.
- On the View menu, click **Project Navigator**. Use the **Hierarchy** tab.
- In the View menu of the Chip Planner, click the **Create LogicLock Region** tab.
- Use a Tcl script.

## Viewing Connections Between LogicLock Regions in the Chip Planner

You can view and edit LogicLock regions using Chip Planner. Select the task **Floorplan Editing (Assignment)** or select any custom task with “Assignment” as the editing mode to manipulate LogicLock regions.

The Chip Planner shows the connections between LogicLock regions. Rather than showing multiple connection lines from one LogicLock region to another, you can select the option of viewing connections between LogicLock regions as a single bundled connection. To use this option, open the Chip Planner floorplan, and on the View menu, click **Generate Inter-region Bundles**.

In the **Generate Inter-region Bundles** dialog box, specify the **Source node to region fanout less than** and the **Bundle width greater than** values.

For more information about the parameters in the **Generate Inter-region Bundles** dialog box, refer to the Quartus II Help.

## Design Analysis Using the Chip Planner

The Chip Planner assists you in visually analyzing your design at any stage of your design cycle. With the Chip Planner tool, you can view post-compilation placement, connections, and routing paths. You can also create LogicLock regions and location assignments. The Chip Planner allows you to create new logic cells and I/O atoms and to move existing logic cells and I/O atoms using the architectural floorplan of your design. You can also see global and regional clock regions within the device, and the connections between both I/O atoms and PLLs and the different clock regions.

From the Chip Planner, you can launch the Resource Property Editor. The Resource Property Editor lets you make changes to the properties and parameters of device resources, and modify connectivity between certain types of device resources. Changes that you perform are logged within the Change Manager. The Change Manager helps you track the various changes you make on your design floorplan, so that you can selectively undo the changes if necessary.

For more information about the Resource Property Editor and the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

The following sections present design analysis procedures and views of Chip Planner, which can be used with any predefined task of the Chip Planner (unless explicitly stated that a certain procedure requires a particular task or editing mode).

### Chip Planner Floorplan Views

The Chip Planner uses a hierarchical zoom viewer that shows various abstraction levels of the targeted Altera device. As you increase the zoom level, the level of abstraction decreases, thus revealing more detail about your design.

#### *First-Level View*

The first level provides a high-level view of the entire device floorplan. You can locate and view the placement of any node in your design. [Figure 10–6](#) shows the Chip Planner's Floorplan first level view of a Stratix device.

**Figure 10–6. Chip Planner’s First-Level Floorplan View**

Each resource is shown in a different color. The Chip Planner floorplan uses a gradient color scheme in which the color becomes darker as the utilization of a resource increases. For example, as more LEs are used in the LAB, the color of the LAB becomes darker.

When you place the mouse pointer over a resource at this level, a tooltip appears that describes, at a high level, the utilization of the resource (Figure 10–7).

**Figure 10–7. Tooltip Message: First-Level View**

### Second-Level View

As you zoom in, the level of detail increases. [Figure 10–8](#) shows the second-level view of the Chip Planner Floorplan for a Stratix device.

**Figure 10–8. Chip Planner's Second Level Floorplan View**

At this level, the contents of LABs and I/O banks and the routing channels that are used to connect resources are all visible.

When you place the mouse pointer over an LE or ALM at this level, a tooltip is displayed ([Figure 10–9](#)) that shows the name of the LE/ALM, the location of the LE/ALM, and the number of resources that are used with that LAB. When you place the mouse pointer over an interconnect, the tooltip shows the routing channels that are used by that interconnect. At this level, you can move LEs, ALMs, and I/Os from one physical location to another.

**Figure 10–9. Tooltip Message: Second-Level View**

### *Third-Level View*

At the third level, which provides a more detailed view, you can see each routing resource that is used within a LAB in the FPGA. [Figure 10–10](#) shows the level of detail at the third level view for a Stratix device.

From the third level, you can move LEs, ALMs, and I/Os from one physical location to another. You can move a resource by selecting, dragging, and dropping it into the desired location. At this level, you can also create new LEs and I/Os when you are in the post-compilation (ECO) mode.

 You can delete a resource only after all of its fan-out connections are removed. Moving nodes in the Floorplan Editing (Assignment) task creates an assignment. However, if you move logic nodes in the Post-Compilation Editing (ECO) task, that change is considered an ECO change.

For more information about Floorplan Assignments, refer to [“Viewing Assignments in the Chip Planner”](#) on page 10–32.

For more information about performing ECOs, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

**Figure 10–10. Chip Planner's Third Level Floorplan View**

### *Bird's Eye View*

The Bird's Eye View (Figure 10–11) displays a high-level picture of resource usage for the entire chip and provides a fast and efficient way to navigate between areas of interest in the Chip Planner.

Figure 10–11. Bird's Eye View

The Bird's Eye View is displayed as a separate window that is linked to the Chip Planner floorplan. When you select an area of interest in the Bird's Eye View, the Chip Planner floorplan automatically refreshes to show that region of the device. As you change the size of the main-view rectangle in the Bird's Eye View window, the main Chip Planner

floorplan window also zooms in (or zooms out). You can make the main-view rectangle smaller in the Bird's Eye View to see more detail on the Chip Planner floorplan window.

The Bird's Eye View is particularly useful when parts of your design that you are interested in are at opposite ends of the chip, and you want to quickly navigate between resource elements without losing your frame of reference.

## Viewing Architecture-Specific Design Information

With the Chip Planner, you can view the following architecture-specific information related to your design:

- **Device routing resources used by your design**—View how blocks are connected, as well as the signal routing that connects the blocks.
- **LE configuration**—View how a logic element (LE) is configured within your design. For example, you can view which LE inputs are used; if the LE utilizes the register, the look-up table (LUT), or both; as well as the signal flow through the LE.
- **ALM configuration**—View how an adaptive logic module (ALM) is configured within your design. For example, you can view which ALM inputs are used, if the ALM utilizes the registers, the upper LUT, the lower LUT, or all of them. You can also view the signal flow through the ALM.
- **I/O configuration**—View how the device I/O resources are used. For example, you can view which components of the I/O resources are used, if the delay chain settings are enabled, which I/O standards are set, and the signal flow through the I/O.
- **PLL configuration**—View how a phase-locked loop (PLL) is configured within your design. For example, you can view which control signals of the PLL are used with the settings for your PLL.
- **Timing**—View the delay between the inputs and outputs of FPGA elements. For example, you can analyze the timing of DATAB input to the COMBOUT output.

In addition, you can modify the following properties of an Altera device with the Chip Planner:

- LEs and ALMs
- I/O cells
- PLLs
- Registers in RAM and DSP blocks
- Connections between elements
- Placement of elements

For more information about LEs, ALMs, and other resources of an FPGA device, refer to the relevant device handbook.

## Viewing Critical Paths

Critical paths are timing paths in your design that have a negative slack. These timing paths can span from device I/Os to internal registers, registers-to-registers, or registers-to-devices I/Os. The View Critical Paths feature displays routing paths in the Chip Planner, as shown in [Figure 10–12](#). The criticality of a path is determined by its slack and is shown in the timing analysis report. Design analysis for timing closure is a fundamental requirement for optimal performance in highly complex designs. The Quartus II Chip Planner helps you close timing on complex designs with its analysis capability.

Viewing critical paths in the Chip Planner helps you analyze why a specific path is failing. You will be able to see if any modification in the placement can potentially reduce the negative slack.

To view critical paths in the Chip Planner while using the Quartus II Classic Timing Analyzer, on the View menu, click **Critical Path Settings**. In the **Critical Path Settings** dialog box, click **Show Path** (see [Figure 10–13 on page 10–22](#)).

If you are using the TimeQuest Timing Analyzer to locate the critical paths, run the Report Timing task from the Custom Reports group in the Tasks pane of the TimeQuest GUI. From the View pane, which lists the failing paths, you can right-click on any failing path or node, and select **Locate Path**. From the pop-up dialog box, select **Chip Planner** to see the failing path in the Chip Planner.

**Figure 10–12. Chip Planner Showing Critical Path**

When viewing critical paths, you can specify the clock in the design you want to view. You determine the paths to be displayed by specifying the slack threshold in the slack field of the **Critical Path Settings** dialog box. This dialog box also helps you to filter specific paths based on the source and destination registers.

Timing settings must be made and a timing analysis performed for paths to be displayed in the floorplan.

For more information about performing static timing analysis with the Quartus II Classic Timing Analyzer, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

For more information about performing static timing analysis with the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Figure 10–13. Critical Path Settings for the Chip Planner

## Viewing Physical Timing Estimates

In the Chip Planner, you can select a resource and see the approximate delay to any other resource on the device. After you select a resource, the delay is represented by the color of potential destination resources. The lighter the color of the resource, the longer the delay.

To see the physical timing map of the device, in the Chip Planner, click the **Layers** icon located next to the **Task** pull-down menu. Under the **Background Color Map**, select **Physical Timing Estimate**. Select a source and move your cursor to a destination resource. The Chip Planner displays the approximate routing delay between your selected source and destination register.

You can use the physical timing estimate information when attempting to improve the Fitter results by manually moving logic in a device or when creating LogicLock regions to group logic together. This feature allows

you to estimate the physical routing delay between different nodes so that you can place critical nodes and modules closer together, and move non-critical or unrelated nodes and modules further apart.

In addition to reducing delay between critical nodes, you can make placement assignments to reduce the routing congestion between critical and noncritical entities and modules. This allows the Quartus II Fitter to meet the design timing requirements.

Note that moving logic and creating manual placements is an advanced technique to meet timing requirements and must be done after careful analysis of the design. Moving nodes in the Floorplan Editing (Assignment) task creates an assignment. However, if you move logic nodes in the Post-Compilation Editing (ECO) task, that change is considered an ECO change.

For more information about Floorplan Assignments, refer to [“Viewing Assignments in the Chip Planner”](#) on page 10–32.

For more information about performing ECOs, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

## Viewing Routing Congestion

The Routing Congestion view allows you to determine the percentage of routing resources used after a compilation. This feature identifies where there is a lack of routing resources. This information helps you to make decisions about design changes that may be necessary to ease the routing congestion and thus meet design requirements. The congestion is visually represented by the color and shading of logic resources. The darker shading represents a greater routing resource utilization. To view the routing congestion in the Chip Planner, click the **Layers** icon located next to the **Task** menu. Under **Background Color Map**, select the **Routing Utilization** map (Figure 10–14).

If you intend to use a HardCopy II device, there is no selection for Background Color. To get to the routing congestion view with HardCopy II, turn on **Routing Congestion**.

**Figure 10–14. Viewing Routing Congestion Map in the Chip Planner**

## Viewing I/O Banks

The Chip Planner can show all of the I/O banks of the device displayed in different colors. To see the I/O bank map of the device, click the **Layers** icon located next to the **Task** menu. Under **Background Color Map**, select the **I/O Banks** map. See [Figure 10–15](#).

Figure 10–15. Viewing I/O Banks in the Chip Planner

All predefined tasks in the Chip Planner show the Block Utilization Map as the default Background Color Map.

## Generating Fan-In and Fan-Out Connections

This feature enables you to view the atoms that fan-in to or fan-out from the selected atom. To remove the connections displayed, use the **Clear Connections** icon in the Chip Planner toolbar. [Figure 10–16](#) shows the fan-in connections for the selected resource.

*Figure 10–16. Generated Fan-In*

## Generating Immediate Fan-In and Fan-Out Connections

This feature enables you to view the immediate resource that is the fan-in or fan-out connection for the selected atom. For example, selecting a logic resource and choosing to view the immediate fan-in enables you to see the routing resource that drives the logic resource. You can generate immediate fan-in and fan-outs for all logic resources and routing resources. To remove the connections that are displayed, use the **Clear Connections** icon in the toolbar. [Figure 10–17](#) shows the immediate fan-out connections for the selected resource.

*Figure 10–17. Immediate Fan-Out Connection*

## Highlight Routing

This feature enables you to highlight the routing resources used for a selected path or connection. Figure 10–18 shows the routing resources used between two logic elements.

---

**Figure 10–18. Highlight Routing**

## Show Delays

You can view the timing delays for the highlighted connections when generating connections between elements. For example, you can view the delay between two logic resources or between a logic resource and a routing resource. [Figure 10-19](#) shows the delays between several logic elements.

**Figure 10-19. Show Delays**

## Exploring Paths in the Chip Planner

You can use the Chip Planner to explore paths between logic elements. The following example uses the Chip Planner to traverse paths from the Timing Analysis report.

### Locate Path from the Timing Analysis Report to the Chip Planner

To locate a path from the Timing Analysis Report to the Chip Planner, perform the following steps:

1. Select the path you want to locate.
2. Right-click the path in the Timing Analysis Report, right-click **Locate**, then click **Locate in Chip Planner (Floorplan & Chip Editor)** (Figure 10–20).

**Figure 10–20. Locate a Timing Path from the Chip Planner Timing Analysis Report**

The screenshot shows a table with columns: Slack, Actual fmax (period), From, To, From Clock, and To Clock. A context menu is open over the 'Locate' option, with 'Locate in Chip Planner (Floorplan & Chip Editor)' selected.

Clock Setup: 'clk'						
	Slack	Actual fmax (period)	From	To	From Clock	To Clock
37	0.085 ns	203.46 MHz ( period = 4.915 ns )	state_m:inst1 filter_tap2	acc:inst3 result[4]	clk	clk
3E			aps:instkxn_1[0]	acc:inst3 result[10]	clk	clk
3E			aps:instkxn_1[1]	acc:inst3 result[11]	clk	clk
4C			aps:instkxn_1[0]	acc:inst3 result[9]	clk	clk
41			aps:instkxn_2[0]	acc:inst3 result[7]	clk	clk
42			aps:instkxn[1]	acc:inst3 result[11]	clk	clk
4E			aps:instkxn_1[1]	acc:inst3 result[10]	clk	clk
44			state_m:inst1 filter_tap2	acc:inst3 result[3]	clk	clk
4E			<ul style="list-style-type: none"> <li>Locate in Assignment Editor</li> <li>Locate in Pin Planner</li> <li>Locate in Timing Closure Floorplan</li> <li><b>Locate in Chip Planner (Floorplan &amp; Chip Editor)</b></li> <li>Locate in Resource Property Editor</li> <li>Locate in Technology Map Viewer</li> <li>Locate in RTL Viewer</li> <li>Locate in Design File</li> </ul>			
4E			Timing Settings...			
47			Save Current Report Section As...			
4E						
49	0.195 ns	208.12 MHz ( period = 4.805 ns )				
50	0.199 ns	208.29 MHz ( period = 4.801 ns )				
51	0.222 ns	209.29 MHz ( period = 4.778 ns )				
52	0.231 ns	209.69 MHz ( period = 4.769 ns )				

Figure 10–21 shows the path that is displayed in the Chip Planner.

**Figure 10–21. Resulting Path**

To view the routing resources taken for a path you have located in the Chip Planner, click the **Highlight Routing** icon in the Chip Planner toolbar, or from the View menu, click **Highlight Routing**.

#### *Analyzing Connections for a Path*

To determine the connections between items in the Chip Planner, use the **Expand Connections/Paths** icon on the toolbar. To add the timing delays between each connection, use the **Show Delays** icon on the toolbar. [Figure 10–22](#) shows the connections for the selected path that are displayed in the Chip Planner.

**Figure 10–23. Viewing Assignments in Chip Planner**

You can make node and pin location assignments and assignments to LogicLock regions and custom regions using the drag-and-drop method in the Chip Planner. The assignments that you create are applied by the Fitter during the next place and route operation.

To learn more about working with location assignments, refer to the Quartus II Help.

### Viewing Routing Channels for a Path in the Chip Planner

To determine the routing channels between connections, click the **Highlight Routing** icon on the toolbar. [Figure 10–24](#) shows the routing channels used for the selected path in the Chip Planner.

**Figure 10–24. Highlight Routing**

You can view and edit resources in the FPGA using the Resource Property Editor mode of the Chip Planner tool. For more information, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

### Cell Delay Table

You can view the propagation delay from all inputs to all outputs for any LE in your design. To see the Cell Delay Table for an atom, select the atom in the Chip Planner and right-click. From the pop-up menu, click **Locate** and then click **Locate in Resource Property Editor**. The Resource Property window shows you the atom properties along with the Cell Delay Table, indicating the propagation delay from all inputs to all outputs. [Figure 10–25](#) shows the Cell Delay Table.

Figure 10–25. Cell Delay Table

## Viewing High and Low Power Tiles in Stratix III Devices in the Chip Planner

The Chip Planner has a predefined task, **Power Analysis (Assignment)**, which shows the power map of a Stratix III device. Stratix III devices have Adaptive Logic Modules (ALMs) that can operate in either high power mode or low power mode. The power mode is set during the fitting process in the Quartus II software. These ALMs are grouped together to form a larger block, called a “tile”.

To learn more about power analyses and optimizations in Stratix III devices, refer to the application note *AN 437: Power Optimization in Stratix III FPGAs*.

When the **Power Analysis (Assignment)** task is selected in the Chip Planner for Stratix III devices, low-power and high-speed tiles are displayed in different colors; yellow tiles operate in a high-speed mode, while blue tiles operate in a low-power mode (see [Figure 10–26](#)). The

editing mode in the Power Analysis task is “Assignment.” In this mode, you can perform all floor plan-related functions for this task; however, you cannot edit any tiles to change the power mode.

**Figure 10–26. Viewing High and Low Power Tiles in a Stratix III Device**

## Timing Closure Floorplan Overview

For the older device families not supported by the Chip Planner, you can perform the floorplan analysis using the Timing Closure Floorplan. The APEX, ACEX, FLEX, and MAX 7000 families of devices are supported only by the Timing Closure Floorplan. This section explains how to use the Timing Closure Floorplan to enhance your FPGA design analysis.

Table 10–1 on page 10–2 lists the device families supported by the Timing Closure Floorplan Editor and the Chip Planner.

To start the Timing Closure Floorplan Editor, on the Assignments menu, click **Timing Closure Floorplan**.

If the device in your project is not supported by the Timing Closure Floorplan, the following message appears: Can't display a floorplan: the current device family is only supported by Chip Planner.

If your target device is supported by the Timing Closure Floorplan, you can also start the Timing Closure Floorplan tool by right-clicking any of the following sources, pointing to **Locate**, and clicking **Locate in Timing Closure Floorplan**:

- Compilation Report
- Node Finder
- Project Navigator
- RTL source code
- RTL Viewer
- Simulation Report
- Timing Report

Figure 10–27 shows the icons in the Timing Closure Floorplan toolbar.

**Figure 10–27. Timing Closure Floorplan Icons**

## Design Analysis Using the Timing Closure Floorplan

The Timing Closure Floorplan Editor allows you to analyze your designs visually before and after performing a full design compilation in the Quartus II software. This floorplan editor, used in conjunction with the Quartus II timing analyzer, provides a method for performing design analysis.

### Timing Closure Floorplan Views

The Timing Closure Floorplan Editor provides the following five views of your design:

- Field view
- Interior Cells view
- Interior Labs view
- Package Top view
- Package Bottom view

#### *Field View*

The Field view provides a color-coded, high-level view of the resources used in the device floorplan. All device resources, such as embedded system blocks (ESBs) and MegaLAB blocks, are outlined. [Figure 10–28](#) shows the Field view of an APEX II device.

**Figure 10–28. Field View of an APEX II Device**

To view the details of a resource in the Field view, select the resource, right-click, and click **Show Details**. To hide the details, select all the resources, right-click, and click **Hide Details** (Figure 10–29).

**Figure 10–29. Show and Hide Details of a Logic Array Block in Field View**

### *Other Views*

You can also view your design in the Timing Closure Floorplan Editor with the Interior Cells, Interior Labs, Package Top, and Package Bottom views. Use the View menu to display the various floorplan views. The Interior Cells view provides a detailed view of device resources, including device pins and individual logic elements within a MegaLAB.

### **Viewing Assignments**

The Timing Closure Floorplan Editor differentiates between user assignments and Fitter placements. User assignments include LogicLock regions and are made by a user.

If the device is changed after a compilation, the user assignment and Fitter placement options cannot be used together. When this situation occurs, the Fitter placement displays the last compilation result and the user assignment displays the floorplan of the newly selected device.

To see the user assignments, click the **Show User Assignments** icon in the Floorplan Editor toolbar, or, on the View menu, point to Assignments and click **Show User Assignments**. To see the Fitter placements, click the

Show Fitter Placements icon in the Floorplan Editor toolbar, or, on the View menu, point to Assignments and click **Show Fitter Placements**. Figure 10–30 shows the Fitter placements.

Figure 10–30. Fitter Placements

## Viewing Critical Paths

The View Critical Paths feature displays routing paths in the floorplan, as shown in Figure 10–31. The criticality of a path is determined by its slack and is also shown in the timing analysis report.

**Figure 10–31. Critical Paths**

To view critical paths in the Timing Closure Floorplan, click the **Critical Path Settings** icon on the toolbar, or, on the View menu, point to Routing and click **Critical Paths Settings**.

When viewing critical paths, you can specify the clock in the design to be viewed. You can determine which paths to display by specifying the slack threshold in the slack field.

Timing settings must be made and timing analysis performed for paths to be displayed in the floorplan.

For more information about performing static timing analyses of your design with a timing analyzer, refer to the *Quartus II Classic Timing Analyzer* and the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*.

Viewing the critical paths is useful for determining the criticality of nodes based on placement. There are a number of ways to view the details of the critical path.

The default view in the Timing Closure Floorplan shows the path with the source and destination registers displayed. You can also view all the combinational nodes along the worst-case path between the source and destination nodes. To view the full path, click on the delay label to select the path, right-click, and select **Show Path Edges**. Figure 10–32 shows the critical path through combinational nodes. To hide the combinational nodes, select the path, right-click, and select **Hide Path Edges**.

 You must view the routing delays to select a path.

**Figure 10–32. Worst-Case Combinational Path Showing Path Edges**

To assign the path to a LogicLock region using the **Paths** dialog box, select the path, right-click, and select **Properties**.

You can determine the maximum routing delay between two nodes within a LogicLock region. To use this feature, on the View menu, point to Routing and click **Show Intra-region Delay**. Place your cursor over a Fitter-placed LogicLock region to see the maximum delay.

For more information about making path assignments with the **Paths** dialog box, refer to “[Timing Closure Floorplan View](#)” on page 10–48.

After running timing analysis, you can locate timing paths from the timing reports file produced. Right-click on any row in the report file, point to **Locate**, and click **Locate in Timing Closure Floorplan**. The Timing Closure Floorplan window opens with the timing path highlighted.

For more information about optimizing your design in the Quartus II software, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*. With the options and tools available in the Timing Closure Floorplan and the techniques described in that chapter, the Quartus II software can help you achieve timing closure in a more time-efficient manner.

### Physical Timing Estimates

In the Timing Closure Floorplan Editor, you can select a resource and see the approximate delay to any other resource on the device. After you select a resource, the delay is represented by the color of potential destination resources. The darker the color of the resource, the longer the delay ([Figure 10–33](#)).

**Figure 10–33. Physical Timing Estimates View**

You can also obtain an approximation of the delay between two points by selecting a source and holding your cursor over a potential destination resource (Figure 10–34).

**Figure 10–34. Delay for Physical Timing Estimate in the Timing Closure Floorplan**

The delays represent an estimate based on probable best-case routing. The delay may be greater than what is shown, depending on the availability of routing resources. In general, there is a strong correlation between the probable and actual delay.

To view the physical timing estimates, click the **Show Physical Timing Estimate** icon, or, on the View menu, point to Routing and click **Show Physical Timing Estimates**.

You can use the physical timing estimate information when manually placing logic in a device. This information allows you to place critical nodes and modules closer together, and non-critical or unrelated nodes and modules further apart, reducing the routing congestion between critical and non-critical entities and modules. This placement enables the Quartus II Fitter to meet the timing requirements.

## Viewing Routing Congestion

The View Routing Congestion feature allows you to determine the percentage of routing resources used after a compilation. This feature identifies where there is a lack of routing resources.

The congestion is shown by the color and shading of logic resources. The darker shading represents a greater routing resource utilization. Logic resources that are red have routing resource utilization greater than the specified threshold.

The routing congestion view is only available from the View menu when you enable the Field View. To view routing congestion in the floorplan, click the **Show Routing Congestion** icon, or, on the View menu, point to Routing and click **Show Routing Congestion**. To set the criteria for the critical path you want to view, click the **Routing Congestion Settings** icon, or, on the View menu, point to Routing and click **Routing Congestion Settings**.

In the **Routing Congestion Settings** dialog box, you can choose the routing resource (interconnect type) you want to examine and set the congestion threshold. Routing congestion is calculated based on the total resource usage divided by the total available resources (Figure 10–35).

**Figure 10–35. Routing Congestion Settings Dialog Box**

If you use the routing congestion viewer to determine where there is a lack of routing resources, examine each routing resource individually to determine which ones use close to 100% of the available resources (Figure 10–36).

**Figure 10–36. Routing Congestion of a Sample Design in a Cyclone Device**

## Timing Closure Floorplan View

The **Timing Closure Floorplan** view provides you with current and previous compilation assignments on one screen. You can display device resources in either of two views: the Field View and the Interior Cells View, as shown in Figure 10–37. The Field View provides an uncluttered view of the device floorplan in which all device resources, such as embedded system blocks (ESBs) and MegaLAB blocks, are outlined. The Interior Cells View provides a detailed view of device resources, including individual logic elements within a MegaLAB and device pins.

Figure 10–37. Timing Closure Floorplan Editor

## LogicLock Regions in the Timing Closure Floorplan

After you have defined a LogicLock region in a device supported by the Timing Closure Floorplan, you must assign resources to it using the Timing Closure Floorplan, the **LogicLock Regions** dialog box, or a Tcl script.

### *Creating LogicLock Regions in the Timing Closure Floorplan Editor*

The Timing Closure Floorplan Editor has toolbar buttons that are used to manipulate LogicLock regions as shown in Figure 10–38. You can use the **Create New LogicLock Region** button to draw LogicLock regions in the device floorplan.

The Timing Closure Floorplan Editor displays LogicLock regions when you select **Show User Assignments** or **Show Fitter Placements**. The type of region determines its appearance in the floorplan.

The Timing Closure Floorplan Editor differentiates between user assignments and Fitter placements. When the **Show User Assignments** option is turned on in the Timing Closure Floorplan, you can see current assignments made to a LogicLock region. When the Fitter Placement option is turned on, you can see the properties of the LogicLock region after the most recent compilation. User-assigned LogicLock regions appear in the Timing Closure Floorplan Editor with a dark blue border. Fitter-placed regions appear in the Timing Closure Floorplan Editor with a magenta border (Figure 10–38).

**Figure 10–38. Timing Closure Floorplan Editor Toolbar Buttons**

### Using Drag and Drop to Place Logic

You can drag selected logic displayed in the **Hierarchy** tab of the **Project Navigator**, in the Node Finder, or in a schematic design file, and drop it into the Timing Closure Floorplan or the **LogicLock Regions** dialog box. [Figure 10–5](#) shows logic that has been dragged from the **Hierarchy** tab of the **Project Navigator** and dropped into a LogicLock region in the **Timing Closure Floorplan**.

### Analyzing LogicLock Region Connectivity Using the Timing Closure Floorplan

To see how logic in LogicLock regions interfaces, view the connectivity between LogicLock regions. This capability is extremely useful when entities are assigned to LogicLock regions. You can also see the fan-in and fan-out of selected LogicLock regions.

To view the connections in the timing closure floorplan, on the View menu, point to Routing and click **Show LogicLock Regions Connectivity**. Figure 10–39 shows standard LogicLock region connections.

**Figure 10–39. LogicLock Region Connections with Connection Count**

As shown in Figure 10–39, the thickness of the connection line indicates how many connections exist between regions. To see the number of connections between regions, on the View menu, point to Routing and click **Show Connection Count**.

LogicLock region connectivity is applicable only when the user assignments are enabled in the Timing Closure Floorplan. When you use floating LogicLock regions, the origin of the user-assigned region is not necessarily the same as that of the Fitter-placed region. You can change the origin of your floating LogicLock regions to that of the most recent

compilation either in the LogicLock Regions window or by selecting **Back-Annotate Origin and Lock** under **Location** in the **LogicLock Regions Properties** dialog box.

To view the fan-in or fan-out of a LogicLock region in the Timing Closure Floorplan, select the user-assigned LogicLock region while the fan-in or the fan-out option is turned on.

To turn on the fan-in option, click the **Show Node Fan-In** icon, or, on the View menu, point to Routing and click **Show Node Fan-In**. To turn on the fan-out option, click the **Show Node Fan-Out** icon, or, on the View menu, point to Routing and click **Show Node Fan-Out**. Only the nodes that have user assignments are visible when viewing fan-in or fan-out of LogicLock regions.

## Additional Quartus II LogicLock Design Features

To complement the **LogicLock Regions** dialog box and Device Floorplan view, the Quartus II software has additional features to help you design with the LogicLock feature.

### *Tooltips*

When you move the mouse pointer over a LogicLock region name on the **LogicLock Regions** dialog box, or over the top bar of the LogicLock region in the Timing Closure Floorplan, the Quartus II software displays a tooltip with information about the properties of the LogicLock region.

Placing the mouse pointer over Fitter-placed LogicLock regions displays the maximum routing delay within the LogicLock region. To enable this feature, on the View menu, point to Routing and click **Show Intra-region Delay**.

### *Reserve LogicLock Region*

The Quartus II software honors all entity and node assignments to LogicLock regions. Occasionally, entities and nodes do not occupy an entire region, which leaves some of the region's resources unoccupied. To increase the region's resource utilization and performance, the Quartus II software's default behavior fills the unoccupied resources with other nodes and entities that have not been assigned to any other region. You can prevent this behavior by turning on the **Reserved** option on the **General** tab of the **LogicLock Region Properties** dialog box. When this option is turned on, your LogicLock region only contains the entities and nodes that you have specifically assigned to your LogicLock region.

In a team-based design environment, this option is extremely helpful in creating a device floorplan. When this option is turned on, each team can be assigned a portion of the device floorplan where placement and optimization of each submodule occurs. Device resources can be distributed to every module without affecting the performance of other modules.

### *Prevent Assignment to LogicLock Regions Option*

Turning on the **Prevent Assignment to LogicLock Regions** option excludes the specified entity or node from being a member of any LogicLock region. However, it does not prevent the entity or node from physically overlapping LogicLock regions. The Fitter places the entity or node anywhere on the device as if no regions exist. For example, if an entire module is assigned to a LogicLock region, when this option is turned on, you can exclude a specific subentity or node from the region.

You can make the **Prevent Assignment to LogicLock Regions** assignment to an entity or node in the Assignment Editor under **Assignment Name**.

### *LogicLock Regions Connectivity*

The Timing Closure Floorplan Editor allows you to see connections between various LogicLock regions that exist within a design. The connection between the regions is drawn as a single line between the LogicLock regions. The thickness of this line is proportional to the number of connections between the regions.

### *Rubber Banding*

On the View menu, click Routing, and select **Rubber Banding** to show existing connections between LogicLock regions and nodes during movement of LogicLock regions within the Floorplan Editor.

### *Show Critical Paths*

You can display the critical paths in the design by turning on the **Show Critical Paths** option. Use this option with the **Critical Paths Settings** option to display paths based on the Timing Analysis report.

### *Show Connection Count*

You can determine the number of connections between LogicLock regions by turning on the **Show Connection Count** option.

### *Analysis and Synthesis Resource Utilization by Entity*

The Compilation Report contains an **Analysis and Synthesis Resource Utilization by Entity** section, which reports accurate resource usage statistics, including entity-level information. This feature is useful when manually creating LogicLock regions.

### *Path-Based Assignments*

You can assign paths to LogicLock regions based on source and destination nodes, allowing you to easily group critical design nodes into a LogicLock region. Any of the following types of nodes can be the source and destination nodes:

- Valid register-to-register path, meaning that the source and destination nodes must be registers
- Valid pin-to-register path, meaning the source node is a pin and the destination node is a register
- Valid register to pin path, meaning that the source node is a register and the destination node is a pin
- Valid pin-to-pin path, meaning that both the source and destination nodes are pins

To open the **Paths** dialog box, on the **General** tab of the **Logic Lock Regions** dialog box, click **Add Path**.

Both "\*" and "?" wildcard characters are allowed for the source and destination nodes. When creating path-based assignments, you can exclude specific nodes using the **Name exclude** field in the **Paths** dialog box. Quartus II ignores all paths passing through the nodes that match the setting in the Name exclude field. For example, consider a case with two paths between the source and destination—one passing through node A and the other passing through node B. If you specify node B in the Name exclude field, only the path assignment through node A is valid.

You can also use the Quartus II Timing Analysis Report to create path-based assignments by following these steps:

1. Expand the **Timing Analyzer** section in the **Compilation Report**.
2. Select any of the clocks in the section labeled "Clock Setup:<clock name>."
3. Locate a path that you want to assign to a LogicLock region. Drag this path from the Report window and drop it in the row labeled in the LogicLock Region pane in the Quartus II GUI.

This operation creates a path-based assignment from the source register to the destination register as shown in the **Timing Analysis Report**.

### *Quartus II Revisions Feature*

When you create, modify, or import LogicLock regions into a top-level design, you may need to experiment with different configurations to achieve your desired results. The Quartus II software Revisions feature provides a convenient way to organize the same project with different settings until an optimum configuration is found.

On the Project menu, click **Revisions**. In the **Revisions** dialog box, create and set revisions. Revision can be based on the current design or any previously created revisions. Each Revision may have an associated description. Revisions are a convenient way to organize the placement constraints created for your LogicLock regions.

### *LogicLock Assignment Precedence*

Conflicts can arise during the assignment of entities and nodes to LogicLock regions. For example, an entire top-level entity might be assigned to one region and a node within this top-level entity assigned to another region. To resolve conflicting assignments, the Quartus II software maintains an order of precedence for LogicLock assignments. The following order of precedence, from highest to lowest, applies:

1. Exact node-level assignments
2. Path-based and wildcard assignments
3. Hierarchical assignments

However, conflicts can also occur within path-based and wildcard assignments. Path-based and wildcard assignment conflicts arise when one path-based or wildcard assignment contradicts another path-based or wildcard assignment. For example, a path-based assignment is made containing a node labeled `X` and assigned to LogicLock region `PATH_REGION`. A second assignment is made using wildcard assignment `X*` with node `X` being placed into region `WILDCARD_REGION`. As a result of these two assignments, node `X` is assigned to two regions: `PATH_REGION` and `WILDCARD_REGION`.

To resolve this type of conflict, the Quartus II software maintains the order in which the assignments were made and treats the most recent assignment created with the highest priority.

Open the **Priority** dialog box by selecting **Priority** on the **General** tab of the **LogicLock properties** dialog box. You can change the priority of path-based and wildcard assignments by using the Up and Down buttons in the **Priority** dialog box. To prioritize assignments between regions, you must select multiple LogicLock regions. Once the regions have been selected, you can open the **Priority** dialog box from the LogicLock Properties window.

### *LogicLock Regions Versus Soft LogicLock Regions*

Normally all nodes assigned to a particular LogicLock region reside within the boundaries of that region. Soft LogicLock regions can enhance design performance by removing the fixed rectangular boundaries of LogicLock regions. When you assign the “Soft” property to a LogicLock region, the Quartus II software attempts to place as many nodes assigned to the region as close together as possible, and has the added flexibility to move nodes outside of the soft region to meet your design performance requirement. This process allows the Quartus II Fitter greater flexibility in placing nodes in the device to meet your performance requirements.

When you assign nodes to a soft LogicLock region, they can be placed anywhere in the device, but if the soft region is the child of a region, the nodes are not assigned outside the boundaries of the first non-soft parent region. If a non-soft parent does not exist (in a design targeting a Stratix II, Stratix GX, Stratix, Cyclone II, Cyclone, or MAX II device), the region floats within the `Root_region`, that is, the boundaries of the device. You can turn on the **Soft Region** option on the **Location** tab of the **LogicLock Region Properties** dialog box.

Soft regions can have an arbitrary hierarchy that allows any combination of parent and child to be a soft region. The **Reserved** option is not compatible with soft regions.

Soft LogicLock regions cannot be back-annotated because the Quartus II software may have placed nodes outside of the LogicLock region, resulting in location assignments incompatible with the region’s origin and size.

Soft LogicLock regions are available for all device families that support floating LogicLock regions.

### *Virtual Pins*

When you compile a design in the Quartus II software, all I/O ports are directly mapped to pins on the targeted device. The I/O port mapping may create problems for a modular and hierarchical design as lower level

modules may have I/O ports that exceed device pins available on the targeted device. Or, the I/O ports may not directly feed a device pin, but instead drive other internal nodes. The Quartus II software accommodates this situation by supporting virtual pins.

The Virtual Pin assignment communicates to the Quartus II software which I/O ports of the design module are internal nodes in the top-level design. These assignments prevent the number of I/O ports in the lower-level modules from exceeding the total number of available device pins. Every I/O port that is designated a virtual pin is mapped to either an LCELL or an ALM, depending on the target device.

Bidirectional, registered I/O pins, and I/O pins with output enable signals cannot be virtual pins.

In the top-level design, these virtual pins are connected to an internal node of another module. Making assignments to virtual pins allows you to place them in the same location or region on the device as that of the corresponding internal nodes in the top-level module. This feature has the added benefit of providing accurate timing information during lower-level module optimization.

Use the following guidelines for creating virtual pins in the Quartus II software:

- Do not declare clock pins
- Nodes or signals that drive physical device pins in the top-level design should not be declared as virtual pins

In the Node Finder, setting **Filter Type to Pins: Virtual** allows you to display all assigned virtual pins in the design. From the Assignment Editor, to access the Node Finder, double-click the **To** field; when the arrow appears on the right side of the field, click the arrow and select **Node Finder**.

## Using LogicLock Methodology for Older Device Families

The LogicLock methodology is recommended as an optimization method only for older device families, such as the MAX II and APEX II device families, that do not support incremental compilation. In this methodology, you optimize your design and lock it down one module at a time. Using the LogicLock feature, you can create and implement each logic module independently in a hierarchical or team-based design. You can use this LogicLock methodology to optimize and preserve timing, placement, or both for devices that do not support incremental compilation.

Using the LogicLock methodology as an optimization strategy is less effective on newer device families such as those device families in the Cyclone and Stratix series of devices. Altera does not recommend using the LogicLock methodology for designs in such devices, although the feature may be supported on some devices in these series. However, you can use LogicLock regions in conjunction with Incremental Compilation to create a floorplan and preserve timing results for these devices in the Stratix and Cyclone series of devices.

For more information about hierarchical and team-based design, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

### The Quartus II LogicLock Methodology

When you use the LogicLock methodology for older devices, you can place the logic in each netlist file in a fixed or floating region in an Altera device. You can then maintain the placement and, if necessary, the routing of your blocks in the Altera device, thus retaining performance.

To design with the LogicLock feature, create a LogicLock region in a supported device and then assign logic to the region. After you optimize the logic placed within the boundaries of a region to achieve the required performance, you must back-annotate the region's contents to lock the logic placement and routing. Locking the placement and routing preserves the performance when you integrate the region with the rest of the design.

Figures 10–40 compares the traditional design flow with the LogicLock design flow.

**Figure 10–40. Traditional Design Flow Compared with Quartus II LogicLock Design Flow**

For more information about block-based design with the LogicLock feature, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

## Improving Design Performance

The LogicLock methodology helps you optimize and preserve performance. You can use the LogicLock regions to place modules, entities, or any group of logic into regions in a device's floorplan. LogicLock assignments can be hierarchical, which allows you to have more control over the placement and performance of each module and group of modules.

In addition to hierarchical blocks, you can apply LogicLock constraints to individual nodes; for example, you can make a wildcard path-based LogicLock assignment on a critical path. This technique is useful if the critical path spans multiple design blocks.

Although LogicLock constraints can improve performance, they can also degrade performance if they are not applied correctly. They can also result in increased resource usage.

## LogicLock Restrictions

During the design process, placing restrictions on nodes or entities in the design is often necessary. These restrictions can conflict with the node or entity assignments for a LogicLock region. To avoid conflicts, consider the order of precedence given to constraints by the Quartus II software during fitting. The following assignments have priority over LogicLock region assignments:

- Assignments to device resources and location assignments
- Fast input-register and fast output-register assignments
- Local clock assignments for Stratix devices
- Custom region assignments
- I/O standard assignments

The Quartus II software removes nodes and entities from LogicLock regions if any of these constraints are applied to them.

After a LogicLock region is back-annotated, the Quartus II software can place the region only in areas of the device with exactly the same resources.

## Preserving Timing Results Using the LogicLock Flow

To preserve the timing results for a design module in the Quartus II software, you must preserve the placement and routing information for all the logic in the design module. For older device families, you can use the LogicLock design methodology to back-annotate logic locations within a LogicLock region, which makes assignments to each node in the design.

For more information about block-based design with the LogicLock feature, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

When preserving logic placement in an Altera device using LogicLock back-annotation, an atom netlist preserves the node names in subblocks of your design. An atom netlist contains design information that fully describes the submodule logic in terms of the device architecture. In the atom netlist, the nodes are fixed as Altera primitives and the node names do not change if the atom netlist does not change. If a node name changes, any placement information associated with that node, such as LogicLock assignments made when back-annotating a region, is invalid and ignored by the compiler.

If all the netlists are contained in one Quartus II project, use the LogicLock flow to back-annotate the logic in each region. If a design region changes, only the netlist associated with the changed region is affected. When you place and route the design using the Quartus II software, the software needs to re-fit only the LogicLock region associated with the changed netlist file.

Turn on the **Prevent further netlist optimization** option when back-annotating a region with the **Synthesis Netlist Optimizations** option, the **Physical Synthesis Optimization** option, or both, turned on. This sets the **Netlist Optimizations** option to **Never Allow** for all nodes in the region, preventing node name changes in the top-level design when the region is recompiled.

You must remove previously back-annotated assignments for a modified block if the node names are different in the newly synthesized version. When you recompile with one new netlist file, the placement and assignments for the unchanged netlist files assigned to other LogicLock regions are not affected. Therefore, you can make changes to code in an independent block and not interfere with another designer's changes, even when all the blocks are integrated into the same top-level design.

With the LogicLock design methodology, you can develop and test submodules without affecting other areas of a design.

## Importing and Exporting LogicLock Regions

This section describes the steps required to import and export the LogicLock regions when you are using the LogicLock methodology as an optimization tool for older devices.

For information about importing and exporting the assignments for lower-level design partitions using the incremental compilation flow, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

For the Quartus II software to achieve optimal placement, you must specify timing assignments, including  $t_{SU}$ ,  $t_{CO}$ , and  $t_{PD}$ , for all clock signals in the design.

To facilitate the LogicLock design flow, the **Timing Closure Floorplan** highlights resources that have back-annotated LogicLock regions.

### *Export the Module*

This section describes how to export a module's constraints in a format that can be imported to a top-level design. To be exported, a module requires design information stored as an atom netlist (VQM or EDF), placement information stored in a Quartus II Settings File, and routing information stored in a Routing Constraints File (.rcf).

### **Atom Netlist Design Information**

The atom netlist contains design information that fully describes the module's logic in terms of an Altera device architecture. If the design was synthesized using a third-party tool and then brought into the Quartus II software, an atom netlist already exists and the node names are fixed. You do not have to generate another atom netlist. However, if you use any synthesis netlist optimizations or physical synthesis optimizations, you must generate a Verilog Quartus Mapping Netlist File (.vqm) using the Quartus II software, because the original atom netlist may have changed as a result of these optimizations.

Turn on the **Prevent further netlist optimization** option when back-annotating a region with the **Synthesis Netlist Optimizations** and/or **Physical Synthesis Optimization** options turned on. This sets the **Netlist Optimizations** to **Never Allow** for all nodes in the region, avoiding the possibility of a node name change when the region is imported into the top-level design.

If you synthesized the design from a VHDL Design File (.vhd), Verilog Design File (.v), Text Design File (.tdf), or Block Design File (.bdf) in the Quartus II software, you must also create an atom netlist to fix the node names. During compilation, the Quartus II software creates a Verilog Quartus Mapping Netlist File in the **atom\_netlists** subdirectory in the project directory.

If the atom netlist is generated by a third-party synthesis tool and the design has a black box library of parameterized modules (LPM) functions or Altera megafunctions, you must generate a Quartus II Verilog Quartus Mapping Netlist File for the black box modules.

For instructions about creating an atom netlist in the Quartus II software, refer to *Saving Synthesis Results to a Verilog Quartus Mapping File* in the Quartus II Help.

When you export LogicLock regions, all your design assignments are exported. Filtering occurs only when the design is imported. However, you can export a subentity of the compilation hierarchy and all of its relevant regions. To do this, right-click on the entity in the **Hierarchy** tab of the **Project Navigator** and click **Export Assignments**.

### Placement Information

The Quartus II Settings File contains the module's LogicLock constraint information, including clock settings, pin assignments, and relative placement information for back-annotated regions. To maintain performance, you must back-annotate the module.

### Routing Information

The Routing Constraints File (.rcf) contains the module's LogicLock routing information. To maintain performance, you must back-annotate the module.

### Exporting the Routing Constraint File and Atom Netlist

To specify the Routing Constraint File and Atom Netlist to export, perform the following steps:

1. Run a full compilation.
2. On the Assignments menu, click **LogicLock Regions Window**.
3. Right-click the region name, and click **Properties**.

4. In the **LogicLock Region Properties** dialog box, click **Back-Annotate Contents**.
5. Enable or disable any of the advanced options such as **Prevent further netlist optimization**.
6. Turn on **Routing**, and click **OK**.
7. In the **LogicLock Region Properties** dialog box, click **OK**.
8. On the Assignments menu, click **Export Assignments**.
9. In the **Export Assignments** dialog box, turn on **Export back-annotated routing** and **Save a node-level netlist of the entire design into a persistent source file**, then click **OK**.

For instructions about exporting a LogicLock region assignment in the Quartus II software, refer to *Importing and Exporting LogicLock Region Assignments* in the Quartus II Help.

### *Import the Module*

To specify the Quartus II Settings File for a specific instance or entity, use the **LogicLock Import File Name** option in the Assignment Editor. This option lets you specify different LogicLock region constraints for each instance of an entity and import them into the top-level design. You can also specify an RCF file with the **LogicLock Routing Constraints File Name** option in the Assignment Editor.

When importing LogicLock regions into the top-level design, you must specify the Quartus II Settings File and Routing Constraints File for the modules in the project. If the design instantiates a module multiple times, the Quartus II software applies the LogicLock regions multiple times.

Before importing LogicLock regions, you must perform analysis and elaboration, or compile the top-level design, to ensure the Quartus II software is aware of all instances of the lower-level modules.

The following sections describe how to specify a Quartus II Settings File for a module and how to import the LogicLock assignments into the top-level design.

### Importing the Routing Constraints File and the Atom Netlist File

To specify the Quartus II Settings File and atom netlist to import, perform the following steps:

1. On the Assignments menu, click **Import Assignments**. In the **Import Assignments** dialog box, click **Advanced**.
2. In the **Advanced Import Settings** dialog box, turn on **Back-annotated routing**.

Now, when you import a LogicLock region, the routing constraint file is also imported.

### Import the Assignments

On the Assignments menu, click **Import Assignments** to import the assignments. The **Import Assignments** dialog box appears. In the **Import Assignments** dialog box, click **Advanced**. The **Advanced Import Settings** dialog box appears. Use the options available in the **Advanced Import Settings** dialog box to control how you import your LogicLock regions.

To prevent spurious no-fit errors, parent or top-level regions with multiple instances (that do not contain back-annotated routing information) are imported with their states set to floating. Otherwise, the region's state remains as specified in the Quartus II Settings File. This default allows the Quartus II software to move LogicLock regions to areas on the device with free resources. A child region is locked or floating relative to its parent region's origin as specified in the module's original LogicLock constraints.

If you want to lock a LogicLock region to a location, you can manually lock down the region in the **LogicLock Regions** dialog box or the Timing Closure Floorplan.

Each imported LogicLock region has a name that corresponds to the original LogicLock region name combined with the instance name in the form of `<instance name> | <original LogicLock region name>`. For example, if a LogicLock region for a module is named `LLR_0` and the instance name for the module is `Filter:inst1`, then the LogicLock region name in the top-level design is `Filter:inst1 | LLR_0`.

### *Compile and Verify the Top-Level Design*

After importing all modules, you can compile and verify the top-level design. The compilation report shows whether system timing requirements are met.

## Back-Annotating Routing Information

LogicLock regions not only allow you to preserve the placement of logic from one compilation to the next, they also allow you to retain the routing inside the LogicLock regions. With both placement and routing locked, you have an extremely portable design module that can be used many times in a top-level design without requiring further optimization.

Back-annotate routing only when necessary because doing so can prevent the Quartus II Fitter from finding an optimal fit for your design.

Back-annotate the routing from the Assignments menu, by choosing **Routing** from the **Back-Annotate Assignments** dialog box.

If you are not using an atom netlist, you must turn on the **Save a node-level netlist of the entire design into a persistent source file** option (on the Assignments menu, click **Back-Annotate Assignments**) if back-annotation of routing is selected. Writing out a Verilog Quartus Mapping Netlist File causes the Quartus II software to enforce persistent naming of nodes when saving the routing information. The Verilog Quartus Mapping Netlist File is then used as the design's source.

Back-annotated routing information is valid only for regions with fixed sizes and locked locations. The Quartus II software ignores the routing information for LogicLock regions you specify as floating and automatically sized.

The **Disable Back-Annotated Node locations** option in the **LogicLock Region Properties** dialog box is not available if the region contains both back-annotated routing and back-annotated nodes.

## Back-Annotating LogicLock Regions

To back-annotate the contents of your LogicLock regions, perform these steps:

1. In the **LogicLock Region Properties** dialog box, click **Back-Annotate Contents**. The **Back-Annotate Assignments** dialog is shown.
2. In the **Back-Annotate Assignments** dialog box, in the **Back annotation type** list, select **Advanced** and click **OK**.
3. In the **LogicLock Region Properties** dialog box, click **OK**.

If you are using the incremental compilation flow, logic back-annotation is not required. Preserve placement results using the Post-Fit Netlist Type instead of making placement assignments with back-annotation as described in this section.

You can also back-annotate routing within LogicLock regions to preserve performance of the regions. For more information about back-annotating routing, refer to [“Back-Annotating Routing Information”](#) on page 10–65.

When you back-annotate a region’s contents, all of the design element nodes appear under **Back-annotated nodes** with an assignment to a device resource under **Node Location**, for example, logic array block (LAB), memory block, or digital signal processing (DSP) block. Each node’s location is the placement of the node after the most recent compilation. If the origin of the region changes, the node’s location changes to maintain the same relative placement. This relative placement preserves the performance of the module. If cell assignments are demoted, the nodes are assigned to LABs rather than directly to logic cells. This provides more flexibility to the Fitter, and improves the chances of a fit.

## Exporting Back-Annotated Routing in LogicLock Regions

To export the LogicLock region routing information, on the Assignments menu, click **Export Assignments**, and in the **Export Assignments** dialog box, turn on **Export Back-annotated routing**. This option generates a Quartus II Settings File and a Routing Constraints File in the specified directory. The Quartus II Settings File contains all LogicLock region properties as specified in the current design. The Routing Constraints File contains all the necessary routing information for the exported LogicLock regions.

This Routing Constraints File works only with the atom netlist for the entity being exported.

Only regions that have back-annotated routing information have their routing information exported when you export the LogicLock regions. All other regions are exported as regular LogicLock regions.

To determine if a LogicLock region contains back-annotated routing, refer to the **Content Status** box shown on the **Contents** tab of the **LogicLock Region Properties** dialog box. If routing has been back-annotated, the status is “Nodes and Routing Back-Annotated”.

The Quartus II software also reports whether routing information has been back-annotated in the Timing Closure Floorplan. LogicLock regions with back-annotated routing have an “R” in the top-left corner of the region.

## Importing Back-Annotated Routing in LogicLock Regions

To import LogicLock region routing information, you must specify the instance that will have its routing information imported. This is done with the assignment LogicLock Routing Constraints File in the Assignment Editor.

A Routing Constraints File must be explicitly specified using the LogicLock **Back-annotated Routing Import File Name** assignment before importing any LogicLock region.

The Quartus II software imports LogicLock regions with back-annotated routing as regions locked to a location and of fixed size.

You can import back-annotated routing if only one instance of the imported region exists in the top level of the design. If more than one instance of the imported region exists in the top level of the design, the routing constraint is ignored and the LogicLock region is imported without back-annotation of routing. This is because routing resources from one part of the device may not be exactly the same in another area of the device.

When importing the Routing Constraints File for a lower level entity, you must use the same atom netlist, that is, the Verilog Quartus Mapping Netlist File that was used to generate the Routing Constraints File. This restriction ensures that the node names annotated in the Routing Constraints File match those in the atom netlist.

## Scripting Support

You can run procedures and create the settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The same information is available in the Quartus II Help, and in PDF format in the *Quartus II Scripting Reference Manual*.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

for information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*.

## Initializing and Uninitializing a LogicLock Region

You must initialize the LogicLock data structures before creating or modifying any LogicLock regions and before executing any of the Tcl commands listed below.

Use the following Tcl command to initialize the LogicLock data structures:

```
initialize_logiclock
```

Use the following command to uninitialize the LogicLock data structures before closing your project:

```
uninitialize_logiclock
```

## Creating or Modifying LogicLock Regions

Use the following Tcl command to create or modify a LogicLock region:

```
set_logiclock -auto_size true -floating true -region \  
<my_region-name>
```

In the above example, the region's size is set to auto and the state set to floating.

If you specify a region name that does not exist in the design, the command creates the region with the specified properties. If you specify the name of an existing region, the command changes all properties you specify, and leaves unspecified properties unchanged.

For more information about creating LogicLock regions, refer to the sections [“Creating LogicLock Regions” on page 10–7](#) and [“Creating LogicLock Regions with the Chip Planner” on page 10–12](#).

## Obtaining LogicLock Region Properties

Use the following Tcl command to obtain LogicLock region properties. This example returns the height of the region named `my_region`.

```
get_logiclock -region my_region -height
```

## Assigning LogicLock Region Content

Use the following Tcl commands to assign or change nodes and entities in a LogicLock region. This example assigns all nodes with names matching `fifo*` to the region named `my_region`.

```
set_logiclock_contents -region my_region -to fifo*
```

You can also make path-based assignments with the following Tcl command:

```
set_logiclock_contents -region my_region -from \
fifo -to ram*
```

For more information about assigning LogicLock Region Content, refer to [“Assigning LogicLock Region Content”](#) on page 10–11.

## Prevent Further Netlist Optimization

Use this Tcl code to prevent further netlist optimization for nodes in a back-annotated LogicLock region. In your code, specify the name of your LogicLock region.

```
foreach node [get_logiclock_contents -region \
<region name> -node_locations] {
    set node_name [lindex $node 0]
    set_instance_assignment -name
ADV_NETLIST_OPT_ALLOWED "NEVER ALLOW" -to $node_name
```

The `get_logiclock_contents` command is in the `logiclock` package.

## Save a Node-Level Netlist for the Entire Design into a Persistent Source File

Make the following assignments to cause the Quartus II Fitter to save a node-level netlist for the entire design into a Verilog Quartus Mapping Netlist File:

```
set_global_assignment \
-name LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT ON
set_global_assignment \
-name LOGICLOCK_INCREMENTAL_COMPILE_FILE <file name>
```

Any path specified in the file name is relative to the project directory. For example, specifying **atom\_netlists/top.vqm** places **top.vqm** in the **atom\_netlists** subdirectory of your project directory.

A Verilog Quartus Mapping Netlist File is saved in the directory specified at the completion of a full compilation.

For more information about saving a node-level netlist, refer to [“Atom Netlist Design Information” on page 10–61](#).

## Exporting LogicLock Regions

Use the following Tcl command to export LogicLock region assignments. This example exports all LogicLock regions in your design to a file called **export.qsf**.

```
logiclock_export -file export.qsf
```

For more information about exporting LogicLock regions refer to [“Export the Module” on page 10–61](#).

## Importing LogicLock Regions

Use the following Tcl commands to import LogicLock region assignments. This example ignores any pin assignments in the imported region.

```
set_instance_assignment -name LL_IMPORT_FILE \
my_region.qsf -to my_destination

logiclock_import -no_pins
```

Running the import command imports the assignment types for each entity in the design hierarchy. The assignments are imported from the file specified in the **LL\_IMPORT\_FILE** setting.

For more information about importing LogicLock regions, refer to [“Import the Module” on page 10–63](#).

## Setting LogicLock Assignment Priority

Use the following Tcl code to set the priority for a LogicLock region’s members. This example reverses the priorities of the LogicLock region in your design.

```
set reverse [list]
for each member [get_logiclock_member_priority] {
    set reverse [insert $reverse 0 $member]
}
set_logiclock_member_priority $reverse
```

For more information about setting the LogicLock assignment priority, refer to [“LogicLock Restrictions” on page 10–59](#).

## Assigning Virtual Pins

Use the following Tcl command to turn on the virtual pin setting for a pin called `my_pin`:

```
set_instance_assignment -name VIRTUAL_PIN ON \
-to my_pin
```

For more information about assigning virtual pins, refer to [“Virtual Pins” on page 10–56](#).

## Back-Annotating LogicLock Regions

The Quartus II software provides the back-annotate Tcl package that allows you to back-annotate the contents of a LogicLock region.

```
logiclock_back_annotate [-h | -help] [-long_help]
[-region <region_name>] [-from <source_name>]
[-to <destination_name>] [-exclude_from] [-exclude_to] [-path_exclude <path_exclude_name>]
[-no_delay_chain] [-no_contents] [-lock] [-routing]
[-resource_filter <resource_filter_value>] [-no_dont_touch]

[-remove_assignments] [-no_demote_lab] [-no_demote_mac] [-no_demote_pin] [-no_demote_ram]
```

For example, the following command back-annotates all nodes and routing in the region, `one_region`.

```
package require ::quartus::backannotate
logiclock_back_annotate -routing -lock -no_demote_lab -region one_region
```

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## Conclusion

Design analysis for timing closure is a fundamental requirement for optimal performance in highly complex designs. With their analysis capability, the Quartus II Timing Closure Floorplan Editor and Chip Planner tools help you close timing quickly on complex designs. Using these tools along with the LogicLock and Incremental Compilation methodologies, enables you to compile your designs hierarchically, preserving the timing results from individual compilation runs. You can use LogicLock regions as part of an incremental compilation methodology to improve your productivity. You can also include a module in one or more projects while maintaining performance and reducing development costs and time-to-market. LogicLock region assignments give you complete control over logic and memory placement, and you can use LogicLock region assignments to improve the performance of non-hierarchical designs as well.

## Document Revision History

Table 10–3 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Updated for the Quartus II 7.2 software release, including: <ul style="list-style-type: none"> <li>● Reorganization of sections to emphasize the Chip Planner.</li> <li>● Updated instructions.</li> </ul>	Updated for the Quartus II 7.2 software release.
May 2007 v7.1.0	This is a new chapter, consisting of material from the following <i>Quartus II 7.0 Handbook</i> chapters: <ul style="list-style-type: none"> <li>● <i>Timing Closure Floorplan</i> (volume 2)</li> <li>● <i>LogicLock Design Methodology</i> (volume 3)</li> <li>● <i>Design Analysis and Engineering Change Management with the Chip Planner</i> (volume 3)</li> </ul> The following changes were also made: <ul style="list-style-type: none"> <li>● All of the information about Floorplan Analysis in these chapters has been integrated into this new chapter. All ECO-related sections have moved to a different chapter.</li> <li>● Updated several screenshots.</li> <li>● Updated device support.</li> <li>● Added Referenced Documents section.</li> </ul>	Updated for the Quartus II 7.1 software release.

# 11. Netlist Optimizations and Physical Synthesis

Q1152007-7.2.0

## Introduction

The Quartus® II software offers advanced netlist optimization options, including physical synthesis, to optimize your design beyond the optimization performed in the course of the standard Quartus II compilation flow. The effect of these options depends on the structure of your design, but netlist optimizations can help improve the performance of your design regardless of the synthesis tool used. Device support for these optimizations varies; see the appropriate section for details.

Netlist optimization options work with your design's atom netlist, which describes a design in terms of Altera®-specific primitives. An atom netlist file can take the form of an Electronic Design Interchange Format file (.edf) or a Verilog Quartus Mapping file (.vqm) generated by a third-party synthesis tool, or a netlist used internally by the Quartus II software. Netlist optimizations are applied at different stages of the Quartus II compilation flow, either during synthesis or during fitting.

The synthesis netlist optimizations occur during the synthesis stage of the Quartus II compilation flow. The synthesis netlist optimizations make changes to the synthesis netlist output from a third-party synthesis tool or make changes as an intermediate step in Quartus II integrated synthesis (one of the optimizations applies only to third-party synthesis netlists). These netlist changes are beneficial in terms of area or speed, depending on your selected optimization technique.

Physical synthesis optimizations take place during the Fitter stage of the Quartus II compilation flow. These optimizations make placement-specific changes to the netlist that improve performance results for a specific Altera device.

This chapter explains how the netlist optimizations in the Quartus II software can modify your design's netlist and help improve your quality of results. The sections [“Synthesis Netlist Optimizations” on page 11-3](#) and [“Physical Synthesis Optimizations” on page 11-11](#) explain how the available optimizations work. This chapter also provides information about preserving your compilation results through back-annotation and writing out a new netlist, and provides guidelines for applying the various options.

When synthesis netlist optimization or physical synthesis options are turned on, the node names for primitives in the design can change. The fact that nodes may be renamed must be considered if you are using a LogicLock™ or verification flow that may require fixed node names, such as the SignalTap® II logic analyzer or formal verification. If your design flow requires fixed node names, you may need to turn off the synthesis netlist optimization and physical synthesis options.

Primitive node names are specified during synthesis. When netlist optimizations are applied, node names may change as primitives are created and removed. Hardware description language (HDL) attributes applied to preserve logic in third-party synthesis tools cannot be honored because those attributes are not written into the atom netlist read by the Quartus II software. If you are synthesizing in the Quartus II software, you can use the Preserve Register (`preserve`) and Keep Combinational Logic (`keep`) attributes to maintain certain nodes in the design.

For more information about using these attributes during synthesis in the Quartus II software, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

## Synthesis Netlist Optimizations

To view and modify the synthesis netlist optimization options, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, select **Synthesis Netlist Optimizations**, and specify the options for performing netlist optimization during synthesis, as shown in [Figure 11–1](#).

**Figure 11–1. Synthesis Netlist Optimizations Page**

The sections [“WYSIWYG Primitive Resynthesis”](#) and [“Gate-Level Register Retiming”](#) on page 11–5 describe these synthesis netlist optimizations, and how they can help improve the quality of results for your design.

### WYSIWYG Primitive Resynthesis

You can use the **Perform WYSIWYG primitive resynthesis (using optimization technique specified in Analysis & Synthesis settings)** synthesis option when you have an atom netlist file that specifies a design as Altera-specific primitives. Atom netlist files can take the form of either an Electronic Design Interchange Format file or a Verilog Quartus Mapping file generated by a third-party synthesis tool. To select this option, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, select **Synthesis Netlist**

**Optimizations**, and turn on **Perform WYSIWYG primitive resynthesis (using optimization technique specified in Analysis & Synthesis Settings)**. If you want to perform WYSIWYG resynthesis on only a portion of your design, you can use the Assignment Editor to assign the **Perform WYSIWYG primitive resynthesis** logic option to a lower-level entity in your design. This option can be used with Arria™ GX, HardCopy® series, Stratix® series, Cyclone® series, MAX® II, or APEX™ series device families.

The Perform WYSIWYG primitive resynthesis option directs the Quartus II software to un-map the logic elements (LEs) in an atom netlist to logic gates, and then re-map the gates back to Altera-specific primitives. This feature allows the Quartus II software to use different techniques specific to the device architecture during the re-mapping process. This feature re-maps the design using the Optimization Technique specified for your project.

To turn on this option, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**. In the **Analysis & Synthesis Settings** page, under **Optimization Technique**, select **Speed**, **Area**, or **Balanced** to specify how the Quartus II technology mapper optimizes the design. The **Balanced** setting is the default for many Altera device families; this setting optimizes the timing critical parts of the design for speed and the rest for area.

Refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook* for details on the Optimization Technique option.

Figure 11–2 shows the Quartus II software flow for this feature.

**Figure 11–2. WYSIWYG Primitive Resynthesis**

The **Perform WYSIWYG primitive resynthesis** option is not applicable if you are using Quartus II integrated synthesis. With the Quartus II synthesis, you do not have to un-map Altera primitives; they are already mapped during the synthesis step using the techniques that are used with the WYSIWYG primitive resynthesis option.

The **Perform WYSIWYG primitive resynthesis** option un-maps and re-maps only logic cell, also referred to as LCELL or LE primitives, and regular I/O primitives (which may contain registers). Double data rate (DDR) I/O primitives, memory primitives, digital signal processing (DSP) primitives, and logic cells in carry/cascade chains are not touched. Logic specified in an encrypted Verilog Quartus Mapping file or an Electronic Design Interchange Format file, such as third-party intellectual property (IP), is not touched.

Turning on this option can cause drastic changes to the node names in the Verilog Quartus Mapping file or Electronic Design Interchange Format file from your third-party synthesis tool, because the primitives in the atom netlist are being broken apart and then remapped within the Quartus II software. Registers can be minimized away and duplicates removed, but registers that are not removed have the same name after remapping.

Any nodes or entities that have the **Netlist Optimizations** logic option set to **Never Allow** are not affected during WYSIWYG primitive resynthesis. To apply this logic option, on the Assignments menu, click **Assignment Editor**. This option disables WYSIWYG resynthesis for parts of your design.

## Gate-Level Register Retiming

The **Perform gate-level register retiming** option enables movement of registers across combinational logic to balance timing, allowing the Quartus II software to trade off the delay between timing-critical paths and non-critical paths. See [Figure 11-3 on page 11-6](#) for an example. This option can be used with Arria GX, HardCopy series, Stratix series, Cyclone series, MAX II, and APEX series device families. To set this option, on the Assignments menu, click **Settings**. In the **Category list**, select **Analysis & Synthesis Settings**, select **Synthesis Netlist Optimizations**. In the **Synthesis Netlist Optimizations** page, turn on **Perform gate-level register retiming**.

The functionality of your design is not changed when the **Perform gate-level register retiming** option is turned on. However, if any registers in your design have the **Power-Up Don't Care** logic option assigned, the values of registers during power-up may change due to this register and logic movement. The **Power-Up Don't Care** logic option is turned on globally by default. To change the default setting for this option, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**. In the **Analysis & Synthesis Settings** page, click **More Settings**.

You can set the **Power-Up Don't Care** logic option for individual registers or entities using the Assignment Editor. You can also specify a power-up value for individual registers or entities with the **Power-Up Level** logic option. Registers that are explicitly assigned power-up values are not combined with registers that have been explicitly assigned other values.

Figure 11-3 shows an example of gate-level register retiming where the 10 ns critical delay is reduced by moving the register relative to the combinational logic.

**Figure 11-3. Gate-Level Register Retiming Diagram**

Register retiming makes changes at the gate level. If you are using an atom netlist from a third-party synthesis tool, you must also use the **Perform WYSIWYG primitive resynthesis** option to un-map atom primitives to gates (so that register retiming can be performed) and then to re-map gates to Altera primitives. If your design uses Quartus II integrated synthesis, retiming occurs during synthesis before the design is mapped to Altera primitives. Megafunctions instantiated in a design are always synthesized using the Quartus II software.

The design flows for the case of integrated Quartus II synthesis and a third-party atom netlist are shown in [Figure 11-4](#).

**Figure 11-4. Gate-Level Synthesis**

The gate-level register retiming option only moves registers across combinational gates. Registers are not moved across LCELL primitives instantiated by the user, memory blocks, DSP blocks, or carry/cascade chains that you have instantiated. Carry/cascade chains are always left intact when performing register retiming.

One benefit of register retiming is the ability to move registers from the inputs of a combinational logic block to the output, potentially combining the registers. In this case, some registers are removed, and one is created at the output, as shown in [Figure 11-5](#).

**Figure 11-5. Combining Registers with Register Retiming**

The register retiming option can only move and combine registers in this type of situation if the following conditions are met:

- All registers have the same clock signal
- All registers have the same clock enable signal
- All registers have asynchronous control signals that are active under the same conditions
- Only one register has an asynchronous load other than VCC or GND

Retiming can always create multiple registers at the input of a combinational block from a register at the output of a combinational block. In this case, the new registers have the same clock and clock enable. The asynchronous control signals and power-up level are derived from previous registers to provide equivalent functionality.

The **Gate-level Retiming** report provides a list of registers that were created and removed during register retiming. To access this report, on the Processing menu, click **Compilation Report**. In the **Analysis & Synthesis** list, select **Optimization Results**, select **Netlist Optimizations**, and click **Gate-level Retiming** (Figure 11-6).

 The node names for these registers change during the retiming process.

**Figure 11-6. Gate-Level Retiming Report**

Register Name	Clock Name	Created/Deleted
1 outff_a	clk	Deleted
2 outff_a~8	clk	Created
3 outff_a~9	clk	Created
4 outff_a~10	clk	Created
5 outff_a~11	clk	Created

You can set the **Netlist Optimizations** logic option to **Never Allow** to prevent register movement during register retiming. This option can be applied either to individual registers or entities in the design using the Assignment Editor.

The following registers are not moved during gate-level register retiming:

- Registers that have any timing constraint other than global  $f_{MAX}$ ,  $t_{SU}$ , or  $t_{CO}$ . For example, any node affected by a Multicycle or Cut Timing assignment is not moved.
- Registers that feed asynchronous control signals on another register.
- Registers feeding the clock of another register.
- Registers feeding a register in another clock domain.
- Registers that are fed by a register in another clock domain.
- Registers connected to serializer/deserializer (SERDES).
- Registers that have the **Netlist Optimizations** logic option set to **Never Allow**.

- Registers feeding output pins (without logic between the register and the pin).
- Registers fed by an input pin (without logic between register and input pin).
- Both registers in a direct connection from input pin-to-register-to-register if both registers have the same clock and the first register does not fan out to anywhere else. These registers are considered synchronization registers.
- Both registers in a direct connection from register-to-register if both registers have the same clock, the first register does not fan out to anywhere else, and the first register is fed by another register in a different clock domain (directly or through combinational logic). These registers are considered synchronization registers.

You can change the retiming behavior for a sequence of synchronization or meta-stability registers by changing the value of the **Retiming Meta-Stability Register Sequence Length** logic option. The value of this option indicates the number of synchronization registers that will not be moved during gate-level register retiming. The default value is 2. To set the value to any number greater than 0, on the Assignments menu, click Settings. In the Settings dialog box, select **Analysis & Synthesis Settings** and click **More Settings**. A value of 1 means that any registers connected to the first register in a register-to-register connection can be moved during retiming. A value of  $n > 1$  means that any registers in a sequence of length 1, 2, ...  $n$  are not moved during gate-level register retiming as long as all of the following are true:

- The first register is fed either directly by a pin or by a register in another clock domain (directly or through combinational logic)
- All registers in the sequence have the same clock
- All but the last register feed the next register in the sequence directly and do not fan out to anywhere else

If you want to consider registers with any of these conditions for register retiming, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** for a given set of registers.

#### *Allow Register Retiming to Trade-Off $t_{SU}/t_{CO}$ with $f_{MAX}$*

To determine whether the Quartus II compiler should attempt to increase  $f_{MAX}$  at the expense of  $t_{SU}$  or  $t_{CO}$  times, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**, and select **Synthesis Netlist Optimizations**. In the **Synthesis Netlist Optimizations** page, turn on **Allow register retiming to trade off  $T_{su}/T_{co}$  with  $F_{max}$** . This option affects the optimizations performed due to the gate-level register retiming option.

When both the **Perform gate-level register retiming** and the **Allow register retiming to trade off Tsu/Tco with Fmax** options are turned on, retiming can affect registers that feed and are fed by I/O pins. If the latter option is not turned on, the retiming option does not touch any registers that connect to I/O pins through one or more levels of combinational logic.

## Preserving Synthesis Netlist Optimization Results

The Quartus II software generates the same results on every compilation for the same source code and settings on a given system. Therefore, it is typically not necessary to take any steps to preserve your results from compilation to compilation. When changes are made to the source code or to the settings, you usually get the best results by allowing the software to compile without using any previous compilation results or location assignments. In some cases, if you avoid running **Analysis & Synthesis**, or **quartus\_map**, and run the Fitter or another desired Quartus II executable instead, you can skip the synthesis stage of the compile.

You can use the incremental compilation feature to preserve synthesis results for a particular partition of your design by choosing a netlist type of post-synthesis.

You should use the incremental compilation flow to preserve compilation results instead of the LogicLock back-annotation flow described here.

For information about the incremental compilation design methodology, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

If you wish, you may preserve the nodes resulting from netlist optimizations. Preserving the nodes may be required if you use the LogicLock flow to back-annotate placement and/or import one design into another. (Note that this is not needed if you use the incremental compilation design flow along with the LogicLock feature).

If you are using any Quartus II synthesis netlist optimization options, you can save your optimized results. To do so, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings**. In the **Compilation Process Settings** page, turn on **Save a node-level netlist of the entire design into a persistent source file**. This option saves your final results as an atom-based netlist in Verilog Quartus Mapping file format. By default, the Quartus II software places the Verilog Quartus Mapping file in the **atom\_netlists** directory under the current project directory. If you want to create a different Verilog Quartus Mapping file

using different Quartus II settings, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings**. In the **Compilation Process Settings** page, change the **File name** setting.

If you are using the synthesis netlist optimizations (and not any physical synthesis optimizations), generating a Verilog Quartus Mapping file is optional. To lock down the location of all logic and device resources in the design with or without a Quartus II-generated Verilog Quartus Mapping file, on the Assignments menu, click **Back-Annotate Assignments** and specify the desired options. You should use back-annotated location assignments unless the design has been finalized. Making any changes to the design invalidates your back-annotated location assignments. If you need to make changes later on, use the new source HDL code as your input files, and remove the back-annotated assignments corresponding to the old code or netlist.

If you create a Verilog Quartus Mapping file and wish to recompile the design, use the new Verilog Quartus Mapping file as the input source file and turn off the synthesis netlist optimizations for the new compilation.

## Physical Synthesis Optimizations

Traditionally, the Quartus II design flow has involved separate steps of synthesis and fitting. The synthesis step optimizes the logical structure of a circuit for area, speed, or both. The Fitter then places and routes the logic cells to ensure critical portions of logic are close together and use the fastest possible routing resources. While this push-button flow produces excellent results, the synthesis stage is unable to anticipate the routing delays seen in the Fitter. Since routing delays are a significant part of the typical critical path delay, performing synthesis operations with physical delay knowledge allows the tool to target its timing-driven optimizations at these parts of the design. This tight integration of the fitting and synthesis processes is known as physical synthesis.

The following sections describe the physical synthesis optimizations available in the Quartus II software, and how they can help improve your performance results. Physical synthesis optimization options can be used with Arria GX, the Stratix and Cyclone series device families, as well as with HardCopy II devices.

If you are migrating your design to a HardCopy II device, you can target physical synthesis optimizations to the FPGA architecture in the FPGA-first flow or to the HardCopy II architecture in the HardCopy-first flow. The optimizations are mapped to the other device architecture during the migration process. Note that you cannot target optimizations to optimize for both device architectures individually because doing so would result in a different post-fitting netlist for each device.

For more information about using physical synthesis with HardCopy devices, refer to the *Quartus II Support of HardCopy Series Devices* chapter in volume 1 of the *Quartus II Handbook*.

To view and modify the physical synthesis optimization options, on the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings** and select **Physical Synthesis Optimizations**, as shown in Figure 11-7.

**Figure 11-7. Physical Synthesis Optimization Settings**

The physical synthesis optimizations are split into two groups: those that affect only combinational logic and not registers, and those that can affect registers. The options are split to allow you to keep your registers intact for formal verification or other reasons.

The following physical synthesis optimizations are available:

- Physical synthesis for combinational logic
- Automatic asynchronous signal pipelining
- Physical synthesis for registers:
  - Register duplication
  - Register retiming

You can control the effect of physical synthesis with the **Physical synthesis effort** option. The default selection is **Normal**. The **Extra** effort setting uses extra compilation time to try to achieve extra circuit performance, while the **Fast** effort setting uses less compilation time than **Normal** but may not achieve the same gains.

All Physical Synthesis optimizations write results to the **Netlist Optimizations** report. To access this report, on the Processing menu, click **Compilation Report**. In the **Category** list, select **Fitter** and select **Compilation Report**. This report provides a list of atom netlist files that were modified, created, and deleted during physical synthesis.

The node names for these atoms change during the physical synthesis process.

Nodes or entities that have the **Netlist Optimizations** logic option set to **Never Allow** are not affected by the physical synthesis algorithms. To access this logic option, on the Assignments menu, click **Assignment Editor**. Use this option to disable physical synthesis optimizations for parts of your design.

## Automatic Asynchronous Signal Pipelining

The **Perform automatic asynchronous signal pipelining** option on the **Physical Synthesis Optimizations** page in the **Fitter Settings** section of the **Settings** dialog box allows the Quartus II Fitter to perform automatic insertion of pipeline stages for asynchronous clear and asynchronous load signals during fitting when these signals negatively affect performance. You can use this option if asynchronous control signal recovery and removal times are not achieving their requirements.

This option improves performance for designs in which asynchronous signals in very fast clock domains cannot be distributed across the chip fast enough due to long global network delays. This optimization performs automatic pipelining of these signals, while attempting to minimize the total number of registers inserted.

The **Perform automatic asynchronous signal pipelining** option adds registers to nets driving the asynchronous clear or asynchronous load ports of registers. This adds register delays (adds latency) to the reset, adding the same number of register delays for each destination using the reset, changing the behavior of the signal in the design. Therefore this option should only be used when adding latency to reset signals does not violate any design requirements. This option also prevents the promotion of signals to global routing resources.

The Quartus II software performs automatic asynchronous signal pipelining only if **Recovery/Removal Analysis** is enabled. Pipelining is allowed only on asynchronous signals that have the following properties:

- The asynchronous signal is synchronized to a clock (a synchronization register drives the signal)
- The asynchronous signal fans-out only to asynchronous control ports of registers

To access the **Recovery/Removal Analysis** option, on the Assignments menu, click **Settings**. In the **Category** list, select **Timing Requirements & Options**. On the **Timing Requirements & Options** page, click **More Settings**.

The Quartus II software does not perform automatic asynchronous signal pipelining on asynchronous signals that have the **Netlist Optimization** logic option set to **Never Allow**.

## Physical Synthesis for Combinational Logic

To resynthesize the design and reduce delay along the critical path using the Quartus II Fitter, on the Assignments menu, click **Settings**. In the **Category** list, select **Fitter Settings** and select **Physical Synthesis Optimizations**. In the **Physical Synthesis Optimizations** page, click **Perform physical synthesis for combinational logic**. The software can accomplish this type of optimization by swapping the look-up table (LUT) ports within LEs so that the critical path has fewer layers through which to travel. See [Figure 11–8](#) for an example. This option also allows the duplication of LUTs to enable further optimizations on the critical path.

**Figure 11–8. Physical Synthesis for Combinational Logic**

In the first case, the critical input feeds through the first LUT to the second LUT. The Quartus II software swaps the critical input to the first LUT with an input feeding the second LUT. This reduces the number of LUTs contained in the critical path. The synthesis information for each LUT is altered to maintain design functionality.

The **Physical synthesis for combinational logic** option affects only combinational logic in the form of LUTs. The registers contained in the affected logic cells are not modified. Inputs into memory blocks, DSP blocks, and I/O elements (IOEs) are not swapped.

The Quartus II software does not perform combinational optimization on logic cells that have the following properties:

- Are part of a chain
- Drive global signals
- Are constrained to a single logic array block (LAB) location
- Have the **Netlist Optimizations** option set to **Never Allow**

If you want to consider logic cells with any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of nodes.

### Physical Synthesis for Registers—Register Duplication

The **Perform register duplication** Fitter option on the **Physical synthesis Optimizations** page in the **Fitter Settings** section of the **Settings** dialog box allows the Quartus II Fitter to duplicate registers based on Fitter placement information. Combinational logic can also be duplicated when this option is enabled. A logic cell that fans out to multiple locations can be duplicated to reduce the delay of one path without degrading the delay of another. The new logic cell may be placed closer to critical logic without affecting the other fan-out paths of the original logic cell.

Figure 11–9 shows an example of register duplication.

**Figure 11–9. Register Duplication**

The Quartus II software does not perform register duplication on logic cells that have the following properties:

- Are part of a chain
- Contain registers that drive asynchronous control signals on another register
- Contain registers that drive the clock of another register
- Contain registers that drive global signals
- Contain registers that are constrained to a single LAB location
- Contain registers that are driven by input pins without a  $t_{SU}$  constraint
- Contain registers that are driven by a register in another clock domain
- Are considered virtual I/O pins
- Have the **Netlist Optimizations** option set to **Never Allow**

For more information about virtual I/O pins, see the *LogicLock Design Methodology* chapter in volume 2 of the *Quartus II Handbook*.

If you want to consider logic cells that meet any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of nodes.

### Physical Synthesis for Registers—Register Retiming

The **Perform register retiming** fitter option in the **Physical Synthesis Optimizations** page in the **Fitter Settings** section of the **Settings** dialog box allows the Quartus II fitter to move registers across combinational logic to balance timing. This option enables algorithms similar to the **Perform gate-level register retiming** option (see “[Gate-Level Register Retiming](#)” on page 11–5). This option applies to the atom level (registers and combinational logic have already been placed into logic cells), and it complements the synthesis gate-level option.

The Quartus II software does not perform register retiming on logic cells that have the following properties:

- Are part of a cascade chain
- Contain registers that drive asynchronous control signals on another register
- Contain registers that drive the clock of another register
- Contain registers that drive a register in another clock domain
- Contain registers that are driven by a register in another clock domain
- Contain registers that are constrained to a single LAB location
- Contain registers that are connected to SERDES
- Are considered virtual I/O pins
- Registers that have the **Netlist Optimizations** logic option set to **Never Allow**

For more information about virtual I/O pins, refer to the *LogicLock Design Methodology* chapter in volume 2 of the *Quartus II Handbook*.

If you want to consider logic cells that meet any of these conditions for physical synthesis, you can override these rules by setting the **Netlist Optimizations** logic option to **Always Allow** on a given set of registers.

## Preserving Your Physical Synthesis Results

Given the same source code and settings on a given system, the Quartus II software generates the same results for every compilation. Therefore, it is typically not necessary to take any steps to preserve your results from compilation to compilation. When changes are made to the source code or to the settings, you usually get the best results by allowing the software to compile without using any previous compilation results or location assignments. However, if you do wish to preserve the compilation results, make sure to follow the guidelines outlined in this section.

You can use the incremental compilation feature to preserve fitting results for a particular partition of your design by choosing a netlist type of post-fit.

You should use the incremental compilation flow to preserve compilation results instead of the LogicLock back-annotation flow described here.

For information about the incremental compilation design methodology, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

If you wish, you can preserve the nodes resulting from physical synthesis. Preserving the nodes may be required if you use the LogicLock flow to back-annotate placement and/or import one design into another. (Note that this is not needed if you use the incremental compilation design flow along with the LogicLock feature).

If you are using any Quartus II physical synthesis optimization options, you can save the nodes in your optimized result using the **Save a node-level netlist into a persistent source file (Verilog Quartus Mapping File)** option on the **Compilation Process Settings** page in the **Settings** dialog box. This option saves your final results as an atom-based netlist in Verilog Quartus Mapping file format. By default, the Quartus II software places the Verilog Quartus Mapping file in the **atom\_netlists** directory under the current project directory. If you want to create a different Verilog Quartus Mapping file using different Quartus II settings, you may do so by changing the **File name** setting on the **Compilation Process Settings** page in the **Settings** dialog box.

If you are using the physical synthesis optimizations and you wish to lock down the location of all LEs and other device resources in the design using the **Back-Annotate Assignments** command, a Verilog Quartus Mapping file netlist is required to preserve the changes that were made to your original netlist. Since the physical synthesis optimizations depend on the placement of the nodes in the design, back-annotating the placement changes the results from physical synthesis. Changing the results means that node names are different, and your back-annotated locations are no longer valid. To access this option, on the Assignments menu, click **Back-Annotate Assignments**.

You should not use a Quartus II-generated Verilog Quartus Mapping file or back-annotated location assignments with physical synthesis optimizations unless the design has been finalized. Making any changes to the design invalidates your physical synthesis results and back-annotated location assignments. If you need to make changes later, use the new source HDL code as your input files, and remove the back-annotated assignments corresponding to the Quartus II-generated Verilog Quartus Mapping file.

To back-annotate logic locations for a design that was compiled with physical synthesis optimizations, first create a Verilog Quartus Mapping file. When recompiling the design with the hard logic location assignments, use the new Verilog Quartus Mapping file as the input source file and turn off the physical synthesis optimizations for the new compilation.

If you are importing a Verilog Quartus Mapping file and back-annotated locations into another project that has any **Netlist Optimizations** turned on, it is important to apply the **Netlist Optimizations = Never Allow** constraint, to make sure node names don't change, otherwise the back-annotated location or LogicLock assignments are invalid.

You should use the incremental compilation flow to preserve compilation results instead of using logic back-annotation.

## Applying Netlist Optimization Options

Netlist optimization options can have various effects on different designs. Designs that are well coded or have already been restructured to balance critical path delays may not see a noticeable difference in performance.

To obtain optimal results when using netlist optimization options, you may need to vary the options applied to find the best results. By default, all options are off. Turning on additional options leads to the largest effect on the node names in the design. Take this into consideration if you are using a LogicLock or verification flow such as the SignalTap II logic analyzer or formal verification that requires fixed or known node names. On average, applying all of the **physical synthesis** options at the **Extra** effort level produces the best results for those options, but adds significantly to the compilation time. You can also use the **Physical synthesis effort** option to decrease the compilation time.

The synthesis netlist optimizations typically do not add much compilation time, relative to the overall design compilation time.

When you are using a third-party atom netlist (Verilog Quartus Mapping file or Electronic Design Interchange Format file), the **WYSIWYG Primitive Resynthesis** option must be turned on in order to use the **Gate-level Register Retiming** option.

The Design Space Explorer (DSE) tool command language (Tcl)/Tk script is provided with the Quartus II software to automate the application of various sets of netlist optimization options.

For more information about using the DSE script to run multiple compilations, refer to the *Design Space Explorer* chapter in volume 2 of the *Quartus II Handbook*. For information about typical performance results using combinations of netlist optimization options and other optimization techniques, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ←
```

The *Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can specify many of the options described in this section either on an instance, or at a global level, or both.

Use the following Tcl command to make a global assignment:

```
set_global_assignment -name <QSF variable name> <value>
```

Use the following Tcl command to make an instance assignment:

```
set_instance_assignment -name <QSF variable name> <value> -to <instance name>
```

### Synthesis Netlist Optimizations

Table 11–1 lists the Quartus II Settings File (.qsf) variable name and applicable values for the settings discussed in “[Synthesis Netlist Optimizations](#)” on page 11–3. The Quartus II Settings File variable name

is used in the Tcl assignment to make the setting along with the appropriate value. The Type column indicates whether the setting is supported as a global setting, an instance setting, or both.

**Table 11–1. Synthesis Netlist Optimizations and Associated Settings**

Setting Name	Quartus II Settings File Variable Name	Values	Type
Perform WYSIWYG Primitive Resynthesis	ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	ON, OFF	Global, Instance
Optimization Technique	<Device Family Name>_OPTIMIZATION_TECHNIQUE	AREA, SPEED, BALANCED	Global, Instance
Perform Gate-Level Register Retiming	ADV_NETLIST_OPT_SYNTH_GATE_RETIME	ON, OFF	Global
Power-Up Don't Care	ALLOW_POWER_UP_DONT_CARE	ON, OFF	Global
Allow Register Retiming to trade off Tsu/Tco with Fmax	ADV_NETLIST_OPT_RETIME_CORE_AND_IO	ON, OFF	Global
Save a node-level netlist into a persistent source file	LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT	ON, OFF	Global
	LOGICLOCK_INCREMENTAL_COMPILE_FILE	<filename>	
Allow Netlist Optimizations	ADV_NETLIST_OPT_ALLOWED	"ALWAYS ALLOW", DEFAULT, "NEVER ALLOW"	Instance

## Physical Synthesis Optimizations

Table 11–2 lists the Quartus II Settings File variable name and applicable values for the settings discussed in “Physical Synthesis Optimizations” on page 11–11. The Quartus II Settings File variable name is used in the Tcl assignment to make the setting, along with the appropriate value. The Type column indicates whether the setting is supported as a global setting, an instance setting, or both.

**Table 11–2. Physical Synthesis Optimizations and Associated Settings (Part 1 of 2)**

Setting Name	Quartus II Settings File Variable Name	Values	Type
Physical Synthesis for Combinational Logic	PHYSICAL_SYNTHESIS_COMBO_LOGIC	ON, OFF	Global
Automatic Asynchronous Signal Pipelining	PHYSICAL_SYNTHESIS_ASYNCHRONOUS_SIGNAL_PIPELINING	ON, OFF	Global

**Table 11–2. Physical Synthesis Optimizations and Associated Settings (Part 2 of 2)**

Setting Name	Quartus II Settings File Variable Name	Values	Type
Perform Register Duplication	PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION	ON, OFF	Global
Perform Register Retiming	PHYSICAL_SYNTHESIS_REGISTER_RETIMING	ON, OFF	Global
Power-Up Don't Care	ALLOW_POWER_UP_DONT_CARE	ON, OFF	Global, Instance
Power-Up Level	POWER_UP_LEVEL	HIGH, LOW	Instance
Allow Netlist Optimizations	ADV_NETLIST_OPT_ALLOWED	"ALWAYS ALLOW", DEFAULT, "NEVER ALLOW"	Instance
Save a node-level netlist into a persistent source file	LOGICLOCK_INCREMENTAL_COMPILE_ASSIGNMENT	ON, OFF	Global
	LOGICLOCK_INCREMENTAL_COMPILE_FILE	<filename>	

## Incremental Compilation

For information about scripting and command line usage for incremental compilation as mentioned in [“Preserving Synthesis Netlist Optimization Results”](#) on page 11–10 or [“Preserving Your Physical Synthesis Results”](#) on page 11–17, refer to the *Quartus II Incremental Compilation* chapter in volume 1 of the *Quartus II Handbook*.

## Back-Annotating Assignments

You can use the `logiclock_back_annotate` Tcl command to back-annotate resources in your design. This command can back-annotate resources in LogicLock regions, and resources in designs without LogicLock regions.

For more information about back-annotating assignments, see [“Preserving Synthesis Netlist Optimization Results”](#) on page 11–10 or [“Preserving Your Physical Synthesis Results”](#) on page 11–17.

The following Tcl command back-annotates all registers in your design.

```
logiclock_back_annotate -resource_filter "REGISTER"
```

The `logiclock_back_annotate` command is in the `backannotate` package.

## Conclusion

Synthesis netlist optimizations and physical synthesis optimizations work in different ways to restructure and optimize your design netlist. Taking advantage of these Quartus II netlist optimizations can help improve your quality of results.

## Document Revision History

The following table shows the revision history for this chapter.

Document Revision History		
Date and Document Version	Changes Made	Summary of Changes
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 11–23.	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>● Added Arria GX as a newly supported device</li> <li>● Added Referenced Documents.</li> </ul>	Updated chapter to include support for Arria GX.
March 2007 v7.0.0	No changes made.	—
November 2006 v6.1.0	Added revision history for document.	—
May 2006 v6.0.0	Minor updates for the Quartus II software version 6.0.0.	—
October 2005 v5.1.0	Chapter 11 was formerly Chapter 9 in version 5.0.	—

<b>Document Revision History</b>		
<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
May 2005 v5.0.0	Chapter 9 was formerly Chapter 8 in version 4.2.	—
December 2004 v2.1	Updated for Quartus II software version 4.2: <ul style="list-style-type: none"> <li>● General formatting and editing updates.</li> <li>● Additional description about fixed and primitive node names for synthesis netlist optimization and physical synthesis options.</li> <li>● Updates to figures.</li> <li>● Clarified APEX support.</li> <li>● Added information about node name changes for atoms during physical synthesis.</li> <li>● Deleted Physical Synthesis Report section.</li> </ul>	—
June 2004 v2.0	<ul style="list-style-type: none"> <li>● Updates to tables and figures.</li> <li>● New functionality in the Quartus II software version 4.1.</li> </ul>	—
Feb. 2004 v1.0	Initial release.	—

### Introduction

The Quartus® II software includes many advanced optimization algorithms to help you achieve timing closure, optimize area, and reduce dynamic power. The various settings and parameters control the behavior of the algorithms. These options provide complete control over the Quartus II software optimization and power techniques.

Each FPGA design is unique. There is no standard set of options that always results in the best performance or power utilization. Each design requires a unique set of options to achieve optimal performance. This chapter describes the Design Space Explorer (DSE), a utility written in Tcl/Tk that automates finding the best set of options for your design. DSE explores the design space of your design by applying various optimization techniques and analyzing the results.

### DSE Concepts

This section explains the concepts and terminology used by DSE.

#### *Exploration Space and Exploration Point*

Before DSE explores a design, DSE creates an exploration space, which consists of Synthesis and Fitter settings available in the Quartus II software. Each group of settings in an exploration space is referred to as a *point*. An exploration space contains one or more points. DSE traverses the points in the exploration space to determine optimal settings for your design.

#### *Seed and Seed Sweeping*

The Quartus II Fitter uses a seed to specify the starting value that randomly determines the initial placement for the current design. The seed value can be any non-negative integer value. Changing the starting value may or may not produce better fitting. However, varying the value of the seed or seed sweeping allows the Quartus II software to determine an optimal value for the current design.

DSE extends Fitter seed sweeping in exploration spaces by providing a method for sweeping through general compilation and Fitter parameters to find the best options for your design. You can run DSE in various exploration space modes, ranging from an exhaustive try-all-options-and-values mode to a mode that focuses on one parameter.

## DSE Exploration

DSE compares all exploration point results with the results of a base compilation, generated from the initial settings that you specify in the original Quartus II project files. As DSE traverses all points in the exploration space, all settings, not explicitly modified by DSE, default to the base compilation setting. For example, if an exploration point turns on register retiming but does not modify the register packing setting, the register packing setting defaults to the value you specified in the base compilation.

DSE performs the base compilation with the settings you specified in the original Quartus II project. These settings are restored after DSE traverses all points in the exploration space.

## General Description

You can use DSE in either the graphical user interface (GUI) or from a command line. To run DSE with the GUI, either click **Design Space Explorer** on the Tools menu in the Quartus II software, or at the command prompt, type:

```
quartus_sh --dse ←
```

To run DSE from a command line, type the following command at the command prompt:

```
quartus_sh --dse -nogui [<options>] ←
```

You can run DSE with the following options:

```
-archive
-concurrent-compiles [0..6]
-custom-file <filename>
-decision-column <"column name">
-exploration-space <"space">
-ignore-failed-base
-ignore-signalprobe
-ignore-signaltap
-llr-restructuring
-lower-priority
-lsf-queue <queue name>
-nogui
-optimization-goal <"goal">
-project <project name>
-revision <revision name>
-run-power
-search-method <"method">
-seeds <seed list>
-skip-base
-slaves <"slave list">
-stop-after-time <dd:hh:mm>
-stop-after-zero-failing-paths
-use-lsf
```

The DSE script is in the default Quartus II software installation in `<Quartus II installation directory>/common/tcl/apps/dse/dse.tcl` on the PC, Solaris, HP-UX, and Linux platforms. You can launch DSE using one of the following methods:

- On the Tools menu, click **Launch Design Space Explorer**.
- On Windows, select **Start > Programs > Altera > Design Space Explorer** or **Quartus II <version number>**.

For more information on DSE, launch the DSE GUI. On the Help menu, click **Contents** or press the **F1** key.

Figure 12–1 shows the DSE user interface. The **Settings** tab is divided into two sections: **Project Settings** and **Exploration Settings**.

**Figure 12–1. DSE User Interface**

## Timing Analyzer Support

DSE supports both the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer. You must set the timing analyzer prior to opening the project in DSE. Once the timing analyzer is set, DSE performs the design exploration with the selected timing analyzer that guides the fitter.

TimeQuest is launched directly from DSE if you set the default timing analyzer to TimeQuest.

## DSE Flow

You can run DSE at any point in the design process. However, Altera recommends that you run DSE late in your design cycle when you are focusing on optimizing performance and power. The results gained from different combinations of optimization options may not persist over large changes in a design. Running DSE in signature mode (refer to “[Signature Mode](#)” on page 12–13) at the midpoint of your design cycle shows you the affect of various parameters such as the register packing logic option on your design.

DSE runs the Quartus II software for every compilation specified in the **Exploration Settings** options. DSE selectively determines the best settings for your design based on the **Optimization Goal** selected for the exploration. The Quartus II software always attempts to achieve all your timing requirements regardless of the Optimization Goal set in DSE. The Optimization Goal changes the metrics that DSE evaluates to determine if one compilation is better than another. Design Space Explorer does not change the behavior of the Quartus II software.

DSE reports the compilation that has the smallest slack. Specifying all timing requirements before you use DSE to explore your design is very important to ensure that DSE finds the optimal set of parameters for your design based on design criteria you set in your initial design.

You can change the initial placement configuration used by the Quartus II Fitter by varying the **Fitter Seed** value. You can enter seed values in the **Seeds** field of the DSE user interface.

To set the seed value on the Assignments menu, click **Fitter Settings** in the **Settings** dialog box.

Compilation time increases as DSE exploration spaces become more comprehensive. Increased compilation time results from running several compilations and comparing the generated results with the original base compilation results.

For typical designs, varying only the seed value results in a 5%  $f_{MAX}$  increase. For example, when compiling with three different seeds, one-third of the time  $f_{MAX}$  does not improve over the initial compilation, one-third of the time  $f_{MAX}$  gets 5% better, and one-third of the time  $f_{MAX}$  gets 10% better.

## DSE Support for Altera Device Families

DSE setting support varies across device families. To see the range of settings DES supports, click the **Advanced Search** radio button on the **Settings** tab, then select the **Advanced** tab to access the settings listed in the following categories:

- Exploration Space
- Optimization Goal
- Search Method

The following device families support all **Advanced** setting types:

- Arria™ GX
- Stratix® III
- Stratix II
- Stratix
- Stratix GX
- Cyclone® III
- Cyclone II
- Cyclone
- MAX® II

The following device families support only the **Advanced Exploration Space** and **Optimization Goal** settings shown in [Table 12–1](#):

- APEX™ 20K
- APEX 20KC
- APEX 20KE
- APEX II
- FLEX 10K®
- FLEX® 10KA
- FLEX 10KE

Click the **Advanced Search** radio button on the **Settings** tab before you select the **Advanced** tab to access the settings in [Table 12–1](#).

**Table 12–1. Advanced Exploration Space Support for APEX 20K, APEX II and FLEX 10K Devices**

Seed sweep	Area optimization space
Signature fitting effort level	Extra effort space
Extra effort for Quartus II Integrated Synthesis Projects	Custom space

## DSE Project Settings

This section provides the following information about DSE project settings:

- Setting up the DSE work environment
- Specifying the revision
- Setting the initial seed
- Quartus II integrated synthesis
- Restructuring LogicLock regions

### Setting Up the DSE Work Environment

From the DSE GUI, you can open a Quartus II project for a design exploration with either of the following actions:

- On the File menu, click **Open Project** and browse to your project.
- Use the **Open** icon to open a project.

### Specifying the Revision

You can specify the revision to be explored with the **Revision** field in the DSE user interface. The **Revision** field is populated after the Quartus II project has been opened.

If no revisions were created in the Quartus II project, the default revision, which is the top-level entity, is used. For more information, refer to *Quartus II Project Management* chapter in volume 2 of the *Quartus II Handbook*.

### Setting the Initial Seed

To specify the seed that DSE uses for an exploration, specify a non-negative integer value in the **Seed** box under **Project Settings** on the **Settings** tab. The seed value determines your design's initial placement in a Quartus II compilation.

To specify a range of seeds, type the low end of the range followed by a hyphen, followed by the high end of the range. For example, 2-5 specifies that DSE uses the values 2, 3, 4, and 5 as seeds.

### Restructuring LogicLock Regions

The **Allow LogicLock Region Restructuring** option allows DSE to modify LogicLock region properties in your design, if any exist. DSE applies the **Soft** property to LogicLock regions to improve timing. In addition, DSE can remove LogicLock regions that negatively affect the performance of the design.

“[Exploration Space](#)” on page 12–10 describes the type of explorations you can perform.

### *Search for Best Performance, Search for Best Area Options, or Search for Lowest Power Option*

Use the **Exploration Settings** list to select the type of exploration to perform: **Search for Best Area**, **Search for Best Performance**, **Search for Lowest Power**, or **Advanced Search**.

The **Search for Best Performance** option uses a predefined exploration space that targets performance improvements for your design. Depending on the device your design targets, you can select up to four predefined exploration spaces: **Low (Seed Sweep)**, **Medium (Extra Effort Space)**, **High (Physical Synthesis Space)**, and **Highest (Physical Synthesis with Retiming Space)**. As you move from **Low** to **Highest**, the number of options explored by DSE increases, causing compilation time to increase.

The **Search for Lowest Power** option uses a predefined exploration space that targets overall power improvements for your design. When **Search for Lowest Power** is selected, DSE automatically runs the PowerPlay Power Analyzer for each point in the space. You must ensure that the PowerPlay Power Analyzer is configured correctly to ensure accurate results. DSE issues a warning if the confidence level for any power estimate is low.

The **Search for Best Area** option uses a predefined exploration space that targets device utilization improvements for your design.

### *Advanced Search Option*

The **Advanced Search** option provides full control over the exploration space, the optimization goal for your design, and the search method used in a design exploration. Refer to “[Performing an Advanced Search in Design Space Explorer](#)” on page 12–9 for detailed information on how to set up and perform an **Advanced Search** in DSE.

You can use **Advanced Search** to define exploration spaces that are equivalent to the **Search for Best Area**, **Search for Lowest Power**, and **Search for Best Performance** options.

## Quartus II Integrated Synthesis

The **Project Uses Quartus II Integrated Synthesis** option works only for designs that have been synthesized with Quartus II integrated synthesis. With this option turned on, DSE explores options that affect the synthesis stage of compilation.

For more information on integrated synthesis options, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

## Performing an Advanced Search in Design Space Explorer

You must make three exploration settings in the **Advanced Search** dialog box before exploring a design. These three settings, **Exploration Space**, **Optimization Goal**, and **Search Method**, are described in the following sections. [Figure 12-2](#) shows the **Advanced Search** dialog box.

You can access the **Advanced** tab only after you open a Quartus II project in DSE and select **Advanced Search** on the **Settings** tab.

**Figure 12-2. DSE Advanced Search Dialog Box**

## Exploration Space

The **Exploration Space** list controls the types of explorations that DSE performs on your design. DSE traverses the points in the exploration space, applying the settings to the design and comparing compilation results to determine the best settings for your design. DSE offers the following exploration space types:

- Seed Sweep
- Extra Effort Spaces
- Physical Synthesis Spaces
- Retiming Spaces
- Area Optimization Space
- Selective Performance Optimization Space
- Custom Space
- Signature mode—Power Optimization Spaces

Not all **Advanced** exploration space types are available for every device family. Refer to [“DSE Support for Altera Device Families” on page 12–6](#) for **Advanced** exploration space support for various device families.

Compilation time increases proportionally to the breadth of the explorations. The exploration space compilation time increases with the number and type of exploration spaces DSE explores, especially with exploration space types that have more optimization options and parameters.

On the Options menu, point to **Advanced**, and turn on **Save Exploration Space to File** to save an XML file representing the exploration space. DSE writes the exploration space to a file named *<project name>.dse* in the project directory. You can modify this file to create a custom exploration space.

For more information on using custom exploration spaces in DSE, refer to [“Creating Custom Spaces for DSE” on page 12–22](#).

### *Seed Sweep*

Enter the seed values in the **Seeds** field in the DSE user interface. There are no “magic” seeds. The variation between seeds is truly random, any non-negative integer value is as likely to produce good results. DSE defaults to seeds 3, 5, 7, and 11. The **Seed Sweep** exploration space does not change your netlist.

The **Seeds** field accepts individual seed values, for example, 2, 3, 4, and 5, or seed ranges, for example, 2-5.

Compilation time increases 1× for every seed value you specify. For example, if you enter five seeds, the compilation time increases to 5× the initial compilation time.

### *Extra Effort Spaces*

The **Extra Effort Space** exploration space adds the **Register Packing** option to the exploration space done by the **Seed Sweep**. The **Extra Effort Space** exploration space also increases the Quartus II Fitter effort during placement and routing. However, the **Extra Effort Space** exploration space does not change your netlist.

### *Physical Synthesis Spaces*

The **Physical Synthesis Space** exploration space adds physical synthesis options such as register retiming and physical synthesis for combinational logic to the options included in the **Extra Effort Space** exploration space. These netlist optimizations move registers in your design. Look-up tables (LUTs) are modified by these options. However, the design behavior is not affected by these options.

For more information about physical synthesis, refer to the *Netlist Optimizations & Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

The **Physical Synthesis for Quartus II Integrated Synthesis Projects** exploration space includes all the options in the **Physical Synthesis** exploration space and explores various Quartus II integrated synthesis optimization options. The **Physical Synthesis for Quartus II Integrated Synthesis Projects** exploration space works only for designs that have been synthesized using Quartus II integrated synthesis software.

### *Retiming Space*

The **Physical Synthesis with Retiming Space** exploration space includes all the options in the **Physical Synthesis Space** exploration space and explores register retiming. Register retiming can move registers in your design.

The **Physical Synthesis Retiming Space for Quartus II Integrated Synthesis Projects** exploration space includes all the options in **Physical Synthesis with Retiming Space** exploration space, and also explores various Quartus II integrated synthesis optimization options. The **Physical Synthesis with Retiming Space for Quartus II Integrated Synthesis Projects** exploration space works only for designs that have been synthesized using the Quartus II integrated synthesis.

### Area Optimization Space

The **Area Optimization Space** exploration space explores options that affect logic cell utilization for your design. These options include register packing and **Optimization Technique** set to **Area**.

### Selective Performance Optimization Space

The Selective Performance Optimization combines a seed sweep with various performance fitter settings to improve the timing of your design. The seed sweep is performed over a limited number of points in such a way that the base settings are not replicated. This is the recommended option for large designs where other spaces may be too large.

### Custom Space

Use the **Custom Space** exploration space to selectively explore the effects of various optimization options on your design. This exploration space gives you complete control over which options are explored and in what mode. In the **Custom Space** mode you can explore all optimization options available in DSE.

Table 12–2 shows the settings adjusted by each exploration space.

Search Type	Exploration Spaces					
	Seed Sweep	Extra Effort	Physical Synthesis	Retiming	Area Optimization	Custom
<b>Analysis and Synthesis Settings</b>						
Optimization technique	—	—	✓	✓	✓	✓
Perform WYSIWYG resynthesis	—	—	✓	✓	✓	✓
Perform gate-level register retiming	—	—	—	✓	—	✓
<b>Fitter Settings</b>						
Fitter seed	✓	✓	✓	✓	✓	✓
Register packing	—	✓	✓	✓	✓	✓
Increase PowerFit fitter effort	—	✓	✓	✓	—	✓
Perform physical synthesis for combinational logic	—	—	✓	✓	—	✓
Perform register retiming	—	—	—	✓	—	✓

*Note to Table 12–2:*

(1) For exploration spaces that includes Quartus II Integrated Synthesis Projects, DSE increases the synthesis effort.

For more information about using custom exploration spaces with DSE, refer to “[Creating Custom Spaces for DSE](#)” on page 12–22.

### Signature Mode

In **Signature** mode, DSE analyzes the  $f_{MAX}$ , slack, compilation time, and area trade-offs of a single parameter. Running the single parameter over multiple seeds, DSE reports the average of the resulting values. With this information you gain a better understanding of how that parameter affects your design. There are four signature mode settings in DSE:

- Signature: Fitting Effort Level
- Signature: Netlist Optimizations
- Signature: Fast Fit
- Signature: Register Packing

Each setting explores a specific optimization option for your design. For example, in **Signature: Register Packing** mode, DSE explores the **Auto Packed Registers** logic option with its four settings (**OFF**, **Normal**, **Minimized Area**, and **Minimize Area with Chains**), and reports the effects of each on your design.

### Optimization Goal

Design metrics are extremely important in exploring your design, whether the metric is performance, logic utilization, or a combination of both. These metrics allow you to determine which compilation is best, based on the design requirements. By specifying options in the **Optimization Goal** settings, you specify your optimization design goals. DSE then uses the **Optimization Goal** settings to determine the best compilation results. [Table 12–3](#) summarizes the six available optimization settings.

**Table 12–3. Optimization Goal Settings (Part 1 of 2)**

Setting	Description
Optimize for Speed	The exploration point containing the smallest worst-case slack value is selected as the best run.
Optimize for Area	The exploration point containing the lowest logic cell count is selected as the best run.
Optimize for Power	The exploration point containing the lowest thermal power dissipation, and, if possible, a positive worst-case slack value, is selected as the best run.
Optimize for Negative Slack and Failing Paths	The exploration point containing the best average negative worst-case slack and lowest number of failing paths is selected as the best run.

**Table 12–3. Optimization Goal Settings (Part 2 of 2)**

Setting	Description
Optimize for Average Period	The exploration point containing the highest average period in a multiclock design is selected as the best run.
Optimize for Quality Fit	The exploration point containing the highest quality of fit is selected as the best run.

## Quality of Fit (QoF)

Quality of Fit (QoF) is a better evaluation of fit than traditional worst-case slack metrics, because QoF considers all timing domains. QoF is not susceptible to the common mistake of accepting a fit because it has marginally better worst-case slack than other marginal timing domains with much worse slack. For example, the traditional worst-case slack metric favors a fit that achieves -2 ns slack for clock A and -5 ns slack for clock B, over a fit that achieves 1 ns slack for clock A and -5.5 ns slack for clock B. By applying a piece-wise linear function to each domain slack value, QoF ensures that large improvements in domains with ample slack do not unnecessarily skew the overall quality assessment of the fit.

To achieve a representative QoF value, ensure that slack values from domains that are easily meeting timing requirements do not offset the slack values from domains that are marginally meeting timing requirements. To correlate these values correctly, DSE applies a piece-wise linear function to the individual slack values before they are added together. This function reduces the improvement per unit of additional slack in a domain, as the domain slack improves. For example, the improvement of 100 ps in a domain that begins with 0 ns of slack is weighted more significantly than a 100 ps improvement in a domain that begins with 10 ns of slack.

To calculate the QoF for a design, use the sum of worst- case slack values for all timing domains reported by timing analysis. Timing domains include: Clock Setup, Clock Hold,  $t_{SU}$ ,  $t_{CO}$ ,  $t_{PD}$ ,  $t_H$ ,  $\min t_{CO}$ ,  $\min t_{PD}$ , and other timing parameters. For example, if clock A has a Clock Setup slack of -500 ps, and clock B has a Clock Setup slack of 200 ps, the QoF for these two domains is -700 ps. The higher the QoF value reported, the better the QoF.

The QoF can be calculated for any fully compiled design by entering the following Tcl command in the Tcl console:

```
source [file join $::quartus(tclpath) apps dse
calculate_quality_of_fit.tcl]
```

All variables in the above statement are predefined; type the statement as shown without any variable substitution.

## Search Method

The **Search Method** setting allows you to control the breadth of the search that DSE performs. DSE provides two search methods: **Exhaustive search of exploration space** and **Accelerated search of exploration space**. These search methods are described in [Table 12–4](#).

<b>Search Method</b>	<b>Description</b>
Exhaustive search of exploration space	Applies all settings available in the exploration space to all seeds specified. This search method yields optimal settings for your design, but this search requires the most time.
Accelerated search of exploration space	Finds the best exploration space for your design by first determining the best settings and then sweeping the settings across all seeds specified.

## DSE Flow Options

You can control the configuration of DSE with the following options:

- [Create a Revision from a DSE Point](#)
- [Change Decision Column](#)
- [Stop Flow When Zero Failing Paths are Achieved](#)
- [Continue Exploration Even If Base Compilation Fails](#)
- [Run Quartus II PowerPlay Power Analyzer During Exploration](#)
- [Archive All Compilations](#)
- [Stop Flow After Time](#)
- [Save Exploration Space to File](#)
- [Ignore SignalTap and SignalProbe Settings](#)
- [Skip Base Analysis and Compilation If Possible](#)
- [Lower Priority of Compilation Threads](#)
- [DSE Configuration File](#)

### Create a Revision from a DSE Point

After you have performed a design exploration with DSE, a Quartus II revision can be made from any exploration point. This option facilitates the creation of multiple revisions based on the same space point for further optimization within the Quartus II software. [Figure 12–3](#) shows the **Create a Revision From a DSE Point** dialog box.

**Figure 12–3. Create a Revision from a DSE Point**

## Change Decision Column

The criteria DSE uses to determine the best space point in an exploration is known as the **Decision** column. As DSE explores a design space, the best exploration point changes according to the following inequality:

$$\langle \text{Current Decision Column Value} \rangle > \langle \text{Previous Decision Column Value} \rangle$$

By default, DSE uses worst-case slack as the **Decision** column for an exploration. The worst-case slack **Decision** column is the greatest slack value in an exploration, which can be I/O timing or clock slack values. You can change the **Decision** column on the Options menu. On the

Options menu, click **Advanced**, and select **Change Decision Column**. Table 12–5 lists the available **Decision** columns. The **Decision** column can be any column within the Quartus II Timing Analyzer Report.

**Table 12–5. DSE Change Decision Columns**

Decision Column Name	Description
Worst-case slack (default)	Determines best exploration point on worst-case slack in the exploration space.
Clock Setup: '<clock name>': Slack	Determines best exploration point on the <clock name> specified.
Clock Setup: '*': Slack	Determines best exploration point on all clocks.
Worst-case minimum $t_{CO}$ Slack	Determines best exploration point on worst case minimum $t_{CO}$ slack.
Worst-case $t_H$ Slack	Determines best exploration point on worst-case $t_H$ slack.
Worst-case $t_{SU}$ Slack	Determines best exploration point on worst case $t_{SU}$ slack.
<any column name>	Determines best exploration point on any column available in the Quartus II timing analysis report file.

## Stop Flow When Zero Failing Paths are Achieved

Instructs DSE to stop exploring the space after it encounters any point, including the base point, that has zero failing paths. DSE uses the failing path count reported in the **All Failing Paths report** column to make this decision.

## Continue Exploration Even If Base Compilation Fails

With the **Continue Exploration Even If Base Compilation Fails** option turned on, DSE continues the exploration even when a design compilation error occurs. For example, if timing settings are not applied to your design, a DSE error occurs. To cause DSE to continue with the exploration instead of halting when an error occurs, turn on this option.

## Run Quartus II PowerPlay Power Analyzer During Exploration

Turn on **Run Quartus II PowerPlay Power Analyzer During Exploration** to invoke the Quartus II PowerPlay Analyzer for every exploration performed by DSE. Using this option can help you debug your design and determine trade-offs between power requirements and performance optimization.

## Archive All Compilations

Turn on **Archive All Compilations** to create a Quartus II Archive File (.qar) for each compilation. These archive files are saved to the **dse** directory in the design's working directory.

## Stop Flow After Time

Turn on **Stop Flow After Time** to stop further exploration after a specified number of days, hours, and/or minutes.

Exploration time might exceed the specified value because DSE does not stop in the middle of a compilation.

## Save Exploration Space to File

Turn on **Save Exploration Space to File** to write out a *<project name>.dse* file containing all options explored by DSE. You can use or modify this file to perform a custom exploration.

## Ignore SignalTap and SignalProbe Settings

DSE uses advanced physical synthesis options that are not compatible with the SignalTap® II or SignalProbe™ features. As a result, DSE issues an error message when a project is opened for exploration that has either SignalTap II or SignalProbe turned on. The error message is similar to the following:

```
Error Opening Project-----  
Project is using SignalProbe. Please turn off  
SignalProbe before using this project with Design Space  
Explorer or Ignore SignalProbe Setting in your Design  
on the Options menu.
```

When the **Ignore SignalTap and SignalProbe Settings** option is turned on, DSE bypasses this check.

If you have already verified the design, you might save compilation time and improve resource utilization by turning this option on.

## Skip Base Analysis and Compilation If Possible

Skip Base Analysis and Compilation If Possible allows the DSE to skip the Analysis and Elaboration stage or the compilation of the base point if base point compilation results are available from a previous Quartus II compilation.

## Lower Priority of Compilation Threads

The **Lower Priority of Compilation Threads** option allows DSE to run the Quartus II executables with the `lower_priority` option. The `lower_priority` option lowers the priority of the Quartus II executable.

## DSE Configuration File

Many options exist that allow you to customize the behavior of each DSE exploration. For example, you can specify seed values or a list of slave computers to be used for a distributed exploration run. Each time you close the DSE GUI it saves these values in a configuration file, **dse.conf**. The next time you launch the DSE GUI, it reads the values from **dse.conf** and restores the previous exploration settings.

Where the **dse.conf** file is stored varies based on the operating system that launches DSE. [Table 12–6](#) specifies the locations where **dse.conf** files are stored based on operating system usage.

<i>Table 12–6. DSE Configuration File Location</i>		
OS	File Location (default)	Comment
Windows	%APPDATA%/Altera/dse.conf	If the variable %APPDATA% is not defined, the configuration file is saved to <b>/.altera.quartus/dse.conf</b>
Unix	<b>~/.altera.quartus/dse.conf</b>	

Settings specified in the DSE command-line mode are not saved to a **dse.conf** configuration file.

## DSE Advanced Information

This section covers advanced features that are available in DSE. These features increase the processing efficiency of design space exploration and provide further customization of the design space.

### Computer Load Sharing in DSE Using Distributed Exploration

When you select **Distribute Compiles to Other Machines**, the DSE uses cluster computing technology to decrease exploration time. DSE uses multiple client computers to compile points in the specified exploration space. When you select the **Distributed DSE** option, DSE functions in one of the following operation modes:

- **Use LSF Resources:** DSE uses the Platform LSF grid computing technology to distribute exploration space points to a computing network.
- **Distribute Compiles to Other Machines** uses a Quartus II master process: DSE acts as a master and distributes exploration space points to client computers.

#### *Distributed DSE Using LSF Resources*

The easiest way to use distributed DSE technology is to submit the compilations to a preconfigured LSF cluster at your local site. For more information on LSF software, refer to [www.platform.com](http://www.platform.com), or contact your system administrator. To run Distributed DSE using LSF resources, from the Options menu, select **Distributed DSE** and click the **Configure Resources** option.

#### *Distributed DSE Using a Quartus II Master Process*

Before DSE can use computers in the local area network to compile points in the exploration space, you must create Quartus II software slave instances on the computers that will be used as clients. Type the following command at a command prompt on a client computer:

```
quartus_sh --qslave ←
```

Repeating this on several computers creates a cluster of Quartus II software slaves for DSE to use. After you have created a set of Quartus II software slaves on the network, add the names of each slave computer in the QSlave tab of the **Configure Resources** dialog box.

To access the **Configure Resources** dialog box, from the Options menu, point to **Distributed DSE** and click **Configure Resources**. To add resources, click **Add** and type the client name. Click **OK**.

Figure 12-4 shows an example of client entries for a distributed search.

Figure 12–4. Client Entry in DSE

At the start of an exploration, DSE assumes the role of a Quartus II software master process and submits points to the slaves on the list to compile. If the list is empty, DSE issues an error and the search stops.

 For more information about running and configuring Quartus slaves, at the command prompt, type:

```
quartus_sh --help=qslave ←
```

 Distributed DSE uses a protocol based on FTP to move files between the master and the slaves. By default, the qslave client listens to port number 1977 for communication with the master. If you are running a firewall on a machine that is running the qslave client, make sure you configure the firewall software such that it allows incoming and outgoing transmission control protocol (TCP) and user datagram protocol (UDP) packets on the port used by qslave.

You must set this up in every machine that is used as a slave in a distributed DSE environment.

 You can change the default port number used by qslave by running the following command:

```
quartus_sh --qslave port=<new_port_number> ←
```

You must use the same version of the Quartus II software to run the slave processes as you use to run DSE. To determine which Quartus II software version that you are using to run DSE, select Help and click **About DSE**. Unexpected results can occur if you mix different Quartus II software versions when using the Distributed DSE feature.

## Concurrent Local Compilations

To reduce compilation time, DSE can compile exploration points concurrently. The **Concurrent Local Compilations** option allows you to specify the number of local compilations that DSE performs. For the **Concurrent Local Compilations** option, you can specify up to six concurrent compilations by choosing an integer value ranging from 1 through 6. You can use this option in conjunction with Distributed DSE. However, your system must have both the appropriate resources and licenses to perform concurrent compilations, and distributed processing. Multiprocessor or multicore systems are recommended for concurrent local compilations.

**Concurrent Local Compilations** require a separate Quartus II software license for each concurrent compilation. For example, if you compile four concurrent compilations, you need four licenses. Be sure before you choose a **Concurrent Local Compilations** value and start compilation that sufficient licenses are available.

## Creating Custom Spaces for DSE

You can use custom spaces to explore combinations of options that are not in the predefined **Exploration Space** list. An exploration space is defined in an XML file. The following sections describe the tags you use to create a **Custom Space** that DSE can process.

A custom space is defined by the following three pairs of tags:

- `<DESIGNSPACE>` and `</DESIGNSPACE>`
- `<POINT>` and `</POINT>`
- `<PARAM>` and `</PARAM>`

### *DESIGNSPACE Tag*

The `<DESIGNSPACE>` tag defines the start of the exploration space of a custom space. The end tag `</DESIGNSPACE>` defines the end of the exploration space. Both of these tags are required for all custom spaces.

### *POINT Tag*

The POINT tag pair must occur within the DESIGNSPACE tag pair. The `<POINT <name>="<stage>" enabled="<value>">` tag defines the start of the exploration point in a custom exploration space. The end tag `</POINT>` defines the end of the exploration point. The POINT tag also allows you to specify the `<stage>` value and whether a particular point is active for a particular DSE exploration.

The "`<stage>`" value in the POINT tag can be one of the following:

- **map**—indicates an Analysis and Synthesis setting change for that point
- **fit**—indicates a Fitter setting change for that point
- **seed**—indicates a Fitter seed change
- **llr**—indicates a LogicLock property change

The "`<value>`" value in the POINT tag can either be "1," indicating that for a specific stage the exploration point is active, or "0" for an inactive point.

An example of a POINT tag is shown in [Example 12-1](#):

---

**Example 12-1. Example of the POINT Tag**

```
<POINT space="map" enabled="1" >
...
</POINT>
```

---

The preceding point indicates a point that has Analysis and Synthesis setting changes and is active during Analysis and Synthesis.

### *PARAM Tag*

The PARAM tag pair must occur within the POINT tag pair. The `<PARAM name="<parameter>">` tag defines the start of a parameter to be modified for a particular exploration point. The end tag `</PARAM>` defines the end of the parameter.

An example of a PARAM tag is shown in [Example 12-2](#):

---

**Example 12-2. Example of the PARAM tag**

```
<PARAM name +"ADV_NETLIST_OPT_SYNTH_GATE_RETIME"> ON </PARAM>
```

---

The **Analysis and Synthesis** settings and the “<parameter>” values are shown in [Table 12-7](#).

**Table 12-7. Analysis and Synthesis Settings** *Note (1)*

Analysis and Synthesis Settings	Description	Value
<device family name>_OPTIMIZATION_TECHNIQUE	Type of optimization technique to use during the Quartus II Analysis and Synthesis stage for the specific device family.	SPEED, AREA, BALANCED
ADV_NETLIST_OPT_SYNTH_GATE_RETIME	Gate-level register retiming.	OFF, ON
ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP	WYSIWYG primitive resynthesis.	OFF, ON
DSE_SYNTH_EXTRA_EFFORT_MODE	Controls the Quartus II software synthesis effort.	MODE_1, MODE_2, MODE_3

**Note to Table 12-7:**

- (1) Not all Analysis and Synthesis settings are available for all device families.

The point in [Example 12-2](#) indicates that the Analysis and Synthesis setting gate-level retiming is turned on for the exploration space point.

[Table 12-8](#) shows the Fitter settings.

**Table 12-8. Fitter Settings** *Note (1)*

Fitter Settings	Description	Value
AUTO_PACKED_REGISTERS_<device family name>	Register packing for the specified device family	NORMAL, MINIMIZE_AREA, MINIMIZE_AREA_WITH_CHAINS, AUTO, SPARSE, SPARSE_AUTO, OFF
INNER_NUM	PowerFit Fitter effort level	{integer value}
PHYSICAL_SYNTHESIS_COMBO_LOGIC	Physical synthesis for combinational logic	OFF, ON
PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION	Physical synthesis for register duplication	OFF, ON
PHYSICAL_SYNTHESIS_REGISTER_RETIMING	Physical synthesis for register retiming	OFF, ON

**Note to Table 12-8:**

- (1) Not all Fitter settings are available for all device families.

## Simple Custom Space

Example 12-3 shows a simple custom exploration space performing a seed sweep with settings for the Analysis and Synthesis and the Fitter compilation stages.

---

### Example 12-3. Simple Custom Exploration Space

```
<DESIGNSPACE>
  <POINT space="map" enabled="1">
    <PARAM name="CYCLONE_OPTIMIZATION_TECHNIQUE">SPEED</PARAM>
    <PARAM name="ADV_NETLIST_OPT_SYNTH_GATE_RETIME">ON</PARAM>
    <PARAM name="ADV_NETLIST_OPT_SYNTH_WYSIWYG_REMAP">ON</PARAM>
    <PARAM name="STRATIX_OPTIMIZATION_TECHNIQUE">SPEED</PARAM>
  </POINT>
  <POINT space="fit" enabled="1">
    <PARAM name="PHYSICAL_SYNTHESIS_REGISTER_RETIMING">ON</PARAM>
    <PARAM name="PHYSICAL_SYNTHESIS_REGISTER_DUPLICATION">
      ON</PARAM>
    <PARAM name="AUTO_PACKED_REG_CYCLONE">OFF</PARAM>
    <PARAM name="AUTO_PACKED_REGISTERS_STRATIX">OFF</PARAM>
    <PARAM name="SEED">3</PARAM>
    <PARAM name="PHYSICAL_SYNTHESIS_COMBO_LOGIC">ON</PARAM>
  </POINT>
</DESIGNSPACE>
```

The example defines a custom exploration space that has two points: one map exploration point which changes synthesis settings, and one fit exploration point which change the Quartus II Fitter settings. The map point sets the optimization technique to speed, turns on gate-level retiming, and turns on the WYSIWYG resynthesis. For the fit point, register retiming, register duplication, and physical synthesis for combinational logic are turned on; register packing is turned off; and a seed value of three is used.

### Custom Space XML Schema

Example 12-4 contains an XML Schema describing the XML format for custom exploration space files. You can use an advanced XML editor or XML verification tool to validate any custom exploration files against this schema.

---

#### Example 12-4. XML Schema

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema" elementFormDefault="qualified"
attributeFormDefault="unqualified">
  <xs:element name="DESIGNSPACE">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="COPYRIGHT" type="xs:string" minOccurs="0"/>
        <xs:element name="POINT" maxOccurs="unbounded">

## Document Revision History

Table 12–9 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 12–27.	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>● Added Arria GX to list of devices that support all Advanced setting types</li> <li>● Removed device-centric specificity in Table 12–7 and Table 12–8 to cover a broader range of devices (device families)</li> <li>● Added Referenced Documents on page 12–27.</li> </ul>	Added support information for the Arria GX device.
March 2007 v7.0.0	Updates for software version 7.0, including: <ul style="list-style-type: none"> <li>● Made minor changes to DSE Support for Altera Device Families</li> <li>● Made minor changes to Distribute DSE Using LSF Resources</li> <li>● Updated XML Schema (Example 12-4)</li> </ul>	Added support information for the Cyclone III device.
November 2006 v6.1.0	Added revision history to the document	Added support information for the Stratix III device.
May 2006 v6.0.0	Updated text for the software version 6.0.0, including information about the new Quartus II TimeQuest Timing Analyzer feature	—
October 2005 v5.1.0	Chapter 12 was formerly Chapter 10 in version 5.0	—
May 2005 v5.0.0	Chapter 10 was formerly Chapter 9 in version 4.2	—
December 2004 v2.1	Updated to reflect the new functionality in software version 4.1, including tables and figures	—
June 2004 v2.0	Updated to reflect the new functionality in software version 4.0, including tables and figures	—
February 2004 v1.0	Initial release	—

## Introduction

Synplicity has developed the Amplify Physical Optimizer physical synthesis software to help designers meet performance and time-to-market goals. You can use this software to create location assignments and optimize critical paths outside the Quartus® II software design environment. The Amplify Physical Optimizer design software, which runs on the Synplify Pro synthesis engine, creates a Tcl script with hard location assignments and LogicLock™ regions to control logic placement in the Quartus II software. Depending on the design, the Amplify Physical Optimizer software can improve Altera® device performance over Synplify Pro-compiled designs by reducing the number of logic levels and the interconnect delays in critical paths. Moreover, the Amplify Physical Optimizer software allows designers to compile multiple implementations in parallel to reduce optimization time.

For more information on the Synplify Pro software, refer to *Synplicity Synplify & SynplifyPro Support* chapter in volume 1 of the *Quartus II Handbook*.

This chapter explains the physical synthesis concepts, including an overview of the Amplify Physical Optimizer software and Quartus II flow.

## Software Requirements

The examples in this document were generated using the following software versions:

- Quartus II, version 5.1
- Amplify Physical Optimizer, version 3.7

## Amplify Physical Synthesis Concepts

The Amplify Physical Optimizer physical synthesis tool uses information about the interconnect architectures of Altera devices to reduce interconnect and logic delays in the critical paths. Timing-driven synthesis tools cannot accurately predict how place-and-route tools function; therefore, determining the real critical path with the synthesis tool is a difficult task.

Synthesis tools create technology-level netlist files that work with floorplans using place-and-route tools. Synthesis tools also define netlist names that are used in place-and-route, which means hard location assignments may not apply in the next revision of the resynthesized netlist as nodes names might have been renamed or removed.

Physical synthesis allows you to create floorplans at the register transfer level (RTL) of a design, giving you the ability to perform logic tunneling and replication. Physical synthesis also gives you the flexibility to make changes at the RTL level, allowing these changes to reflect in previously planned paths.

Physical synthesis uses knowledge of the FPGA device architecture to place paths into customized regions. This process will minimize interconnect delays as interconnect and placement information influences the synthesis process of the design.

When the Amplify Physical Optimizer software synthesizes a design, it creates a **.vqm** atom-netlist and Tcl script files, which are read by the Quartus II software. You can create a Quartus II project with the VQM netlist as the top-level module and source the Tcl script generated by the Amplify Physical Optimizer software. The Tcl script sets the design's device, timing constraints (Timing Driven Compilation [TDC] value, multicycle paths, and false paths), and any other constraints specified by the Amplify Physical Optimizer software. After you source the Tcl script, you can compile the design in the Quartus II software.

Refer to [“Forward Annotating Amplify Physical Optimizer Constraints into the Quartus II Software”](#) on page 13–12 for more information on setting up a Quartus II project with Amplify Physical Optimizer Tcl script files.

After the Quartus II software compiles the design, the software performs a timing analysis on the design. The timing analysis reports all timing-related information for the design. If the design does not meet the timing requirements, you can use the timing analysis numbers as a reference when running the next iteration of physical synthesis through the Amplify Physical Optimizer software. This same timing analysis information is also reported in a file called `<revision name>.tan.rpt` in the design directory.

## Amplify-to-Quartus II Flow

If timing requirements are not met with the Amplify Physical Optimizer flow, you should first place and route the design in the Quartus II software without physical constraints. After compilation, you can determine which critical paths should be optimized in the Amplify Physical Optimizer tool in the next iteration. Figure 13-1 shows the Amplify Physical Optimizer design flow.

**Figure 13-1. Software Design Flow**

### Initial Pass: No Physical Constraints

The initial iteration involves synthesizing the design in the Amplify Physical Optimizer software without physical constraints.

Before beginning the physical synthesis flow, run an initial pass in the Amplify Physical Optimizer without physical constraints. At the completion of every Quartus II compilation, the Quartus II Timing Analyzer performs a comprehensive static timing analysis on your design and reports your design's performance and any timing violations. If the design does not meet performance requirements after the first pass, additional passes can be made in the Amplify software.

### *Create New Implementations*

To set the Amplify Physical Optimizer software options, perform the following steps:

1. Compile the design with the **Resource Sharing** and **FSM Compiler** options selected and the **Frequency** setting specified in MHz. For optimal synthesis, the Amplify software includes the retiming, pipelining, and FSM Explorer options. For designs with multiple clocks, set the frequency of individual clocks with Synthesis Constraints Optimization Environment (SCOPE).
2. Select **New Implementation**. The **Options for Implementation** dialog box appears.
3. Specify the part, package, and speed grade of the targeted device in the **Device** tab.
4. Turn on the **Map Logic to Atoms** option in the **Device Mapping Options** dialog box.
5. Turn off the **Disable I/O Insertion** and **Perform Cliqing** options.
6. Specify the name and directory in the **Implementation Results** tab. The result format should be VQM, and you should select **Optional Output Files** as the **Write Vendor Constraint File** option so that the software can generate the Tcl script containing the project constraints.
7. Specify the number of critical paths and the number of start and end points to report in the **Timing Report** tab. [Figure 13–2](#) shows the main Amplify Physical Optimizer project window.

These steps create a directory where the results of this pass are recorded. Ensure that the Amplify Physical Optimizer software implementation options are set as described in the initial pass.

Figure 13–2. Amplify Physical Optimizer Project Window

## Iterative Passes: Optimizing the Critical Paths

In the iterative passes, you optimize the design by placing logic in the device floorplan within the Amplify software. Amplify's floorplan is a high-level view of the device architecture. The floorplan view is dependent upon the target device family. When the Amplify Physical Optimizer re-optimizes the current critical path, additional critical paths may be created. Continue to add new constraints to the existing floorplan until it meets the performance requirements. The design may need several iterations to meet these performance requirements. Since optimizing critical paths involves trying different implementations, the creation of various Amplify project implementations will help in organizing the placement of logic in the floorplan.

## Using the Amplify Physical Optimizer Floorplans

When designs do not meet performance requirements with the initial pass through the Amplify Physical Optimizer software, you can create location assignments to reduce interconnect and logic delays to improve your design's performance.

You must determine which paths to constrain based on the critical paths from the previous implementation. When Quartus II projects are launched with the Amplify Tcl script, the Quartus II software generates a *<revision name>.tan.rpt* file that lists the critical paths for the design. You can then create custom structure regions for critical paths. After critical paths are implemented in a floorplan with the Amplify Physical Optimizer software, you must resynthesize the design. The software will then attempt to optimize the critical paths and reduce the number of logic levels. After the Amplify Physical Optimizer software resynthesizes the design, the Quartus II software must compile the new implementation. If the design does not meet timing requirements, perform another physical synthesis iteration.

Use the following steps to create a floorplan in the Amplify Physical Optimizer software:

1. Click the **New Physical Constraint File** icon at the top of the Amplify Physical Optimizer window.
2. Click **Yes** on the **Estimation Needed** dialog box; the floorplan window appears (Figure 13–3).

**Figure 13–3. Stratix 1S20 Floorplan in the Amplify Physical Optimizer Software**

The floorplan view is located at the top of the screen and the RTL view is at the bottom of the screen.

You can specify modules or individual paths in the Amplify Physical Optimizer software. Using modules can quickly resolve timing problems.

Use the following steps in the software to create a floorplan module:

1. Create a region in the Amplify Physical Optimizer device floorplan window and select the module in the RTL view of the design.
2. Drag the module to the new region. The software will then report the utilization of the region.
3. Resynthesize the design in the software to reoptimize the critical path after the modules have location constraints.
4. Write out the placement constraints into the VQM netlist and the Tcl script.

Repeat the above procedure to create as many regions as required.

## Multiplexers

To create a floorplan for critical paths with one or more multiplexers, create multiple regions and assign the multiplexer to one region and the logic to another. [Figure 13–4](#) shows placing critical paths with multiplexers.

**Figure 13–4. Placing Critical Paths with Multiplexers**

If the critical path contains a multiplexer feeding a register, create a region and place the multiplexer along with the entire critical path in the region (Figure 13–5).

**Figure 13–5. Critical Paths with Multiplexers Feeding Registers**

If the critical path is too large for the region, divide the critical path and ensure that the multiplexer and register are in the same region. Figure 13–6 shows large critical paths with multiplexers feeding registers.

**Figure 13–6. Large Critical Paths with Multiplexers Feeding Registers**

## Independent Paths

Designs may have two or more independent critical paths. To create an independent path in the Amplify Physical Optimizer software, follow the steps below:

1. Create a region and assign the first critical path to that region.
2. Create another region, leaving one MegaLAB structure between the first and second regions.
3. Assign the second critical path to the second region.

## Feedback Paths

If critical paths have the same start and end points, follow the steps below in the Amplify Physical Optimizer software (Figure 13-7):

1. Select the register and instance not directly connected to the register.
2. Right-click and select **Filter Schematic** twice.
3. Highlight the line leading out of the register and either press **P** or right-click the line. Select **Expand Paths**. Assign this logic to a region.

**Figure 13-7. Critical Paths with the Same Starting or Ending Points**

If the critical path does not include I/O pins, create region in columns C2 or C3.

## Starting and Ending Points

Figure 13-8 shows a critical path that has multiple starting and ending points. Use **Find** to display all the starting and ending points in the RTL view in Amplify. Expand the paths between those points. If there is unrelated logic between the multiple starting points and ending points,

assign the starting points and ending points to the same region. Similarly, if there is unrelated logic between starting points and multiple ending points, assign the starting points and ending points to the same region.

**Figure 13–8. Critical Paths with Multiple Starting or Ending Points**

If the two critical paths share a register at the starting or ending point, assign one critical path to one region, and assign the other critical path to an adjacent region. Figure 13–9 shows two critical paths that share a register.

**Figure 13–9. Two Critical Paths Sharing a Register**

If the fanout is on the shared region, replicate the register and assign both registers to two regions (Figure 13–10). This is done by dragging the same register to the required regions. Entities and nodes are also replicated by performing the same procedure.

**Figure 13–10. Fanout on a Shared Region**

## Utilization

Designs with device utilizations of 90% or higher may have difficulties during fitting in the Quartus II software. If the device has several finite state machines, you should implement the state machines with sequential encoding, as opposed to one-hot encoding.

To check area utilization, check the Amplify Physical Optimizer **log** file and **.srr** file for region utilization, after the mapping stage is complete. On the Run menu, click **Estimate Area** to update the utilization estimates.

## Detailed Floorplans

If the critical path does not meet timing requirements after physical optimization, you can create new regions to achieve timing closure. It is recommended that regions do not overlap. Regions should either be entirely contained in another region or remain entirely outside of it. Select the logic requiring optimization from the existing region. Deselect the logic and assign it to the new region. Run the Amplify Physical Optimizer software on the design with the modified physical constraints. Then place and route the design.

## Forward Annotating Amplify Physical Optimizer Constraints into the Quartus II Software

The Amplify Physical Optimizer software simplifies the forward annotating of both timing and location constraints into the Quartus II software through the generation of three Tcl scripts. At the completion of a physical synthesis run, in the Amplify Physical Optimizer software, the following Tcl scripts are generated:

- `<project name>_cons.tcl`
- `<project name>.tcl`
- `<project name>_rm.tcl`

Table 13–1 provides a description of each script’s purpose.

<b>Tcl File</b>	<b>Description</b>
<code>&lt;project name&gt;_cons</code>	This Tcl script will create and compile a Quartus II project. The <code>&lt;project name&gt;.tcl</code> will automatically be sourced when this script is sourced.
<code>&lt;project name&gt;</code>	This script contains forward annotation of constraint information including clock frequency, duty cycle, location, etc.
<code>&lt;project name&gt;_rm</code>	This script removes any previous constraints from the project. The removed constraint is saved in <code>&lt;project name&gt;_prev.tcl</code>

To forward annotate Amplify Physical Optimizer's constraints into the Quartus II software you must use `quartus_cmd`. The `quartus_cmd` command must be used as Amplify Physical Optimizer's Tcl scripts are not compatible with `quartus_sh`. The following command will execute the `<project name>_cons`, which will create a Quartus II project with all Amplify Physical Optimizer constraints forward annotated, and will perform a compilation.

```
<command prompt>quartus_cmd f-my_project_cons.tcl ←
```

 You must run the `<project name>_cons.tcl` first.

After compilation, you may customize the project either in the Quartus II GUI or sourcing a custom Tcl script.

Refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook* for more information on creating and understanding Tcl scripts in the Quartus II software.

## Altera Megafunctions Using the MegaWizard Plug-In Manager with the Amplify Software

When you use the Quartus II MegaWizard® Plug-In Manager to set up and parameterize a megafunction, it creates either a VHDL or Verilog HDL wrapper file. This file instantiates the megafunction (a black box methodology) or, for some megafunctions, generates a fully synthesizable netlist for improved results with EDA synthesis tools such as Synplify (a clear box methodology).

### *Clear Box Methodology*

The MegaWizard Plug-In Manager-generated fully synthesizable netlist is referred to as a clear box methodology because the Amplify Physical Optimizer software can “see” into the megafunction file. The clear box feature enables the synthesis tool to report more accurate timing estimates and take better advantage of timing driven optimization.

To turn on the clear box, go to the Tools menu, and select the **MegaWizard Plug-In Manager**. Turn on the **Generate Clearbox body (for EDA tools only)** option. This option is only for certain megafunctions. If this option does not appear, then clear box models are not supported for the selected megafunction. Turning on this option causes the MegaWizard Plug-In Manager to generate a synthesizable clear box netlist instead of the megafunction wrapper file described in “[Black Box Methodology](#)” on page 13–14.

### **Using MegaWizard Plug-In Manager-generated Verilog HDL Files for Clear Box Megafunction Instantiation**

If you check the `<output file>_inst.v` option on the last page of the wizard, the MegaWizard Plug-In Manager generates a Verilog HDL instantiation template file for use in your Synplify design. This file can help you instantiate the megafunction clear box netlist file, `<output file>.v`, in your top-level design. Include the megafunction clear box netlist file in your Amplify Physical Optimizer project and the information gets passed to the Quartus II software in the Amplify Physical Optimizer-generated VQM output file.

### **Using MegaWizard Plug-In Manager-generated VHDL Files for Clear Box Megafunction Instantiation**

If you check the `<output file>.cmp` and `<output file>_inst.vhd` options on the last page of the wizard, the MegaWizard Plug-In Manager generates a VHDL component declaration file and a VHDL instantiation template file for use in your design. These files help to instantiate the megafunction clear box netlist file, `<output file>.vhd`, in your top-level design. Include

the megafunction clear box netlist file in your Amplify Physical Optimizer project and the information gets passed to the Quartus II software in the Amplify Physical Optimizer-generated VQM output file.

### *Black Box Methodology*

The MegaWizard Plug-In Manager-generated wrapper file is referred to as a black-box methodology because the megafunction is treated as a “black box” in the Amplify Physical Optimizer software. The black box wrapper file is generated by default in the MegaWizard Plug-In Manager and is available for all megafunctions.

The black-box methodology does not allow the synthesis tool any visibility into the function module thus not taking full advantage of the synthesis tool's timing driven optimization. For better timing optimization, especially if the black box does not have registered inputs and outputs, add timing models to black boxes.

For more information on instantiating MegaWizard Plug-In Manager modules or black boxes, refer to the *Synplicity Synplify & SynplifyPro Support* chapter in volume 1 of the *Quartus II Handbook*.

## Conclusion

Physical synthesis uses improved delay estimation to optimize critical paths. The Amplify Physical Optimizer software uses the hierarchical structure of logic and interconnect in Altera devices so that designers can direct a critical path to be placed into several well-defined blocks. The Amplify Physical Optimizer-to-Quartus II software flow is one of the steps to solving the problem of achieving timing closure through physical synthesis.

---

Programmable logic can accommodate changes to a system specification late in the design cycle. Last-minute design changes, commonly referred to as engineering change orders (ECOs), are small changes to the functionality of a design after the design has been fully compiled. This section describes how the Chip Planner feature in the Quartus II software supports ECOs by allowing quick and efficient changes to your logic late in the design cycle.

This section includes the following chapter:

- [Chapter 14, Engineering Change Management with the Chip Planner](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

Programmable logic can accommodate changes to a system specification late in the design cycle. In a typical engineering project development cycle, the specification for the programmable logic portion is likely to change after engineering development begins or while integrating all system elements.

Last-minute design changes, commonly referred to as engineering change orders (ECOs), are small changes to the functionality of a design after the design has been fully compiled. A design is fully compiled when synthesis and place-and-route are completed.

The Chip Planner supports ECOs by allowing quick and efficient changes to your logic late in the design cycle. It provides a visual display of your post place-and-route design mapped to the device architecture of your chosen FPGA, from LAB placement in the device to each mapped Logic Element (LE) or Adaptive Logic Module (ALM). You can analyze your design with the visual display to alter how device resources are mapped to support ECOs.

This chapter addresses the impact that ECOs have on the design cycle, discusses the design flow for performing ECOs, and describes how you can use the Chip Planner to perform ECOs.

In addition to performing ECOs, the Chip Planner allows you to perform detailed analysis on routing congestion, relative resource usage, logic placement, LogicLock™ and customized regions, fan-ins and fan-outs, paths between registers, and delay estimates for paths.

For detailed information about using the Chip Planner for design analysis, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

The Chip Planner supports the following device families:

- Arria™ GX
- Stratix® III
- Stratix II
- Stratix II GX
- Stratix
- Stratix GX

- HardCopy® II
- HardCopy
- Cyclone® III
- Cyclone II
- Cyclone
- MAX II®

## Engineering Change Orders

ECOs are typically performed during the verification stage of a design cycle. When a small change is required on a design, such as modifying a PLL for a different clock frequency or routing a signal out to a pin for analysis, recompilation of the entire design can be time consuming, especially for larger designs. Because several iterations of small design changes can occur during the verification cycle, recompilation times can quickly add up. Furthermore, a full recompilation due to a small design change can result in the loss of previous design optimizations.

Performing ECOs, instead of performing a full recompilation on your design, limits the change only to the affected portions of logic.

This section discusses the areas in which ECOs have an impact on a system design and how the Quartus II software can help you optimize the design in these areas. The following topics are discussed in this section:

- [“Performance”](#)
- [“Compilation Time” on page 14–3](#)
- [“Verification” on page 14–3](#)
- [“Documentation” on page 14–4](#)

### Performance

Making a small change to the design functionality can result in a loss of previous design optimizations. Typical examples of design optimizations are floorplan optimizations and physical synthesis. Ideally, you should preserve previous design optimizations.

The Chip Planner allows you to perform ECOs directly on the post place-and-route database of your design. Any changes you make are restricted to the affected device resources, so the timing performance of the remaining portions of your design are not affected. The Chip Planner performs design rule checks on all changes to prevent illegal modifications to your design.

Additionally, the Quartus II software offers an incremental compilation feature that preserves the optimizations and placement of your design during recompilation. This feature allows you to create partitions of your

design, so that if a change is required after the design is fully placed and optimized, only the affected partition is recompiled to implement the change.

The incremental compilation flow fully supports performing ECOs with the Chip Planner.

When recompiling a project with the Quartus II incremental compilation enabled, the compiler preserves all ECOs performed with the Chip Planner in partitions that have not been modified.

For more information about how to use the incremental compilation feature in the Quartus II software, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

For more information about using the ECO flow in conjunction with incremental compilation, refer to [“Using Incremental Compilation in the ECO Flow”](#) on page 14–38.

## Compilation Time

In the traditional programmable logic design flow, a small change in the design requires a complete recompilation of the design. A complete recompilation of the design consists of synthesis and place-and-route. Making small changes to the design to reach the final implementation on a board can be a long process. Since the Chip Planner works only on the post place-and-route database, you can implement your design changes in minutes without performing a full compilation.

## Verification

After you make a design change, you can verify the impact to your design. To verify that you have not violated timing, you can perform a static timing analysis using the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer after you check and save your netlist changes within the Chip Planner.

For more information about the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*. For more information about the Quartus II Classic Timing Analyzer, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

Additionally, you can perform a gate-level or timing simulation of the ECO-modified design by using the post place-and-route netlist generated by the Quartus II software.

## Documentation

All ECOs made with the Chip Planner are logged in the Change Manager to provide a track record of all changes. By using the Change Manager, you can easily revert back to the original post-fit netlist or you can pick and choose which ECOs you want to have applied.

For more information about the Change Manager, refer to [“Change Manager”](#) on page 14–36.

Additionally, the Quartus II software provides support for multiple compilation revisions of the same project. You can use ECOs made with the Chip Planner in conjunction with revision support to compare several different ECO changes and to provide the ability to revert back to previous project revisions.

# ECO Design Flow

Figure 14–1 shows the design flow for performing ECOs.

**Figure 14–1. Design Flow to Support ECO Changes**

For iterative verification cycles, implementing small design changes at the netlist level can be faster than making an RTL code change. As such, making ECO changes are especially helpful when you debug the design on silicon and need a fast turnaround to generate a programming file for debugging the system.

A typical ECO application occurs when you uncover a problem on the board and isolate the problem to the appropriate nodes or I/O cells on the device. You must be able to correct the functionality quickly and generate a new programming file. Performing small changes using the Chip Planner allows you to modify the post place-and-route netlist directly. This bypasses the need to perform synthesis and logic mapping, thus decreasing the turn around time for programming file generation during the verification cycle. If the change corrects the problem, no modification of the HDL source code is necessary. You can use the Chip Planner to perform the following ECO-related changes to your design:

- Document the changes made with the Change Manager
- Easily recreate the steps taken to produce design changes
- Generate EDA simulation netlists for design verification
- Perform static timing analysis on the design

The Quartus II software can help reduce recompilation time with incremental recompilation for more complex changes that require HDL source code modifications.

## The Chip Planner Overview

The Chip Planner provides a visual display of device resources. It shows the arrangement and usage of the resource atoms in the device architecture that you are targeting. Resource atoms are the building blocks for your device, such as ALMs, LEs, PLLS, DSP blocks, memory block, or IOEs.

The Chip Planner also provides an integrated platform for design analysis and for making ECOs to your design after place-and-route. The toolset consists of the Chip Planner (providing a device floorplan view of your mapped design) and two integrated subtools—the Resource Property Editor and the Change Manager.

For analysis, the Chip Planner can show logic placement, LogicLock and custom regions, relative resource usage, detailed routing information, routing congestion, fan-ins and fan-outs, paths between registers, and delay estimates for paths. Additionally, the Chip Planner allows you to create location constraints or resource assignment changes, such as moving or deleting logic cells or I/O atoms using the device floorplan. For ECO changes, the Chip Planner enables you to create, move, or delete logic cells in the post place-and-route netlist for fast programming file generation. Additionally, you can open the Resource Property Editor

from the Chip Planner to edit the properties of resource atoms or to edit the connections between them. All changes to resource atoms and connections are logged automatically with the Change Manager.

## Opening the Chip Planner

To open the Chip Planner, on the Tools menu, click **Chip Planner**. Alternatively, click the **Chip Planner** icon on the Quartus II software toolbar.

Optionally, the Quartus II software supports cross-probing to open the Chip Planner. To open the Chip Planner by cross-probing, use the shortcut menu in the following tools:

- Compilation Report
- Project Navigator window
- RTL source code
- Timing Closure Floorplan
- Node Finder
- Simulation Report
- RTL Viewer

If the device in your project is not supported by the Chip Planner and you attempt to open the Chip Planner, the Quartus II software displays the following message: "Can't display Chip Planner: the current device family is unsupported." In such cases, use the Timing Closure Floorplan.

For more information about the Timing Closure Floorplan, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

## The Chip Planner Toolbar

The Chip Planner gives you design analysis capabilities with a user-friendly GUI. You can perform many functions within the Chip Planner from the menu items or by clicking the icons on the toolbar. [Figure 14–2](#) shows an example of the Chip Planner toolbar and describes the commonly used icons.

Figure 14–2. Chip Planner Toolbar

You can also customize the icons on the Chip Planner toolbar. To customize the icon toolbar if the Chip Planner window is attached, on the Tools menu, click **Customize Chip Planner**. If the Chip Planner window is detached, on the Tools menu, click **Customize**.

For more information about using the Chip Planner for analyzing your design, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

## The Chip Planner Tasks and Layers

The Chip Planner enables you to set up tasks to quickly implement ECO changes or manipulate assignments for the floorplan of the device. Each task consists of an editing mode and a set of customized layer settings.

The editing modes available in the Chip Planner are the Assignment mode and the ECO mode. Assignment mode enables you to create or manipulate LogicLock regions and make location constraints on the resource atoms used in your design. Assignments made are reflected in the Quartus II Settings File (.qsf) and the Assignment Editor. With ECO mode, you can create atoms, delete atoms, and move existing atoms to different locations. The changes made with ECO mode are made in the post place-and-route database. You can analyze your design with both modes.

The layers settings enable you to specify the displayed graphic elements for a given task. You can turn off the display of specific graphic elements to increase the window refresh speed and reduce visual clutter when viewing complex designs. The Background Color Map indicates the relative level of resource usage for different areas of the device. For example, **Routing Utilization** indicates the relative routing utilization and **Physical Timing Estimate** indicates the relative physical timing.

The Chip Planner has predefined tasks that enable you to quickly implement ECO changes or manipulate assignments for the floorplan of the device. The Chip Planner provides the following predefined tasks:

- Post-Compilation Editing (ECO)
- Floorplan Editing (Assignment)
- Power Analysis (Assignment)—available for Stratix III devices only

You can choose the predefined task by selecting it in the **Task** pull down menu located in the upper right corner of the Chip Planner floorplan view.

To customize your own task, click on the layers icon to open the **Layers Settings** dialog box.

For more information about assignments and analysis with the Chip Planner, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

For more information about performing ECOs using the ECO mode, refer to “[Performing ECOs with the Chip Planner \(Floorplan View\)](#)” on page 14–15.

### The Chip Planner Floorplan Views

The Chip Planner uses a hierarchical zoom viewer that shows various abstraction levels of the targeted Altera device. As you increase the zoom level, the level of abstraction decreases, thus revealing more detail about your design.

## First-Level View

The first zoom level provides a high-level view of the entire device floorplan. This view provides a level of detail similar to the Field View in the Quartus II Timing Closure Floorplan. You can locate and view the placement of any node in your design. Figure 14–3 shows the Chip Planner Floorplan first-level view of a Stratix device.

**Figure 14–3. The Chip Planner First-Level (Highest) Floorplan View (Stratix Family Device)**

Each resource is shown in a different color to help you distinguish between resources. The Chip Planner Floorplan uses a gradient color scheme in which the color becomes darker as the utilization of a resource increases. For example, as more LEs are used in the LAB, the color of the LAB becomes darker.

When you place the mouse pointer over a resource at this level, a tooltip appears that describes, at a high level, the utilization of the resource (Figure 14-4).

**Figure 14-4. Tooltip Message: First-Level View**

## Second-Level View

As you zoom in, you see an increase in the level of detail. Figure 14-5 shows the second-level view of the Chip Planner Floorplan for a Stratix device.

**Figure 14-5. The Chip Planner Second-Level Floorplan View (Stratix Family Device)**

At this level you can see the contents of LABs and I/O banks. You also see the routing channels that are used to connect resources. When you place the mouse pointer over an LE or ALM at this level, a tooltip is displayed (Figure 14-6) that shows the name of the LE/ALM, the location of the LE/ALM, and the number of resources that are used with that LAB. When you place the mouse pointer over an interconnect, the tooltip shows the routing channels that are used by that interconnect.

**Figure 14–6. Tooltip Message: Second-Level View**

### Third-Level View

At the third level, which provides the greatest level of detail, you can see each routing resource that is used within a LAB in the FPGA. [Figure 14–7](#) shows the level of detail at the third-level view for a Stratix device.

**Figure 14–7. The Chip Planner Third-Level View**

The second and third level of zoom allows you to move LEs, ALMs, and I/Os from one physical location to another. You can move a resource by selecting, dragging, and dropping it into the desired location. At this level you can also create new LEs and I/Os.

For more information about creating atoms, deleting atoms, or reallocating device atoms, refer to the section [“Performing ECOs with the Chip Planner \(Floorplan View\)”](#) on page 14–15.

For more information about creating Floorplan Assignments, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

### **Bird's Eye View**

The Bird's Eye View ([Figure 14–8](#)) displays a high-level picture of resource usage for the entire chip and provides a fast and efficient way to navigate between areas of interest in the Chip Planner.

**Figure 14–8. Bird's Eye View**

The Bird's Eye View is displayed as a separate window that is linked to the Chip Planner Floorplan. When you select an area of interest in the Bird's Eye View, the Chip Planner Floorplan automatically refreshes to show that region of the device. As you change the size of the main-view rectangle in the Bird's Eye View window, the main Chip Planner

Floorplan window also zooms in (or zooms out). You can make the main-view rectangle smaller in the Bird's Eye View to see more detail on the Chip Planner Floorplan window.

The Bird's Eye View is particularly useful when the parts of your design that you are interested in are at opposite ends of the chip and you want to quickly navigate between resource elements without losing your frame of reference.

## Performing ECOs with the Chip Planner (Floorplan View)

You can manipulate resource atoms in the Chip Planner when you select the ECO editing mode. The following ECO changes can be performed with the Chip Planner Floorplan view:

- [“Creating Atoms”](#)
- [“Deleting Atoms” on page 14–20](#)
- [“Moving Atoms” on page 14–20](#)

To select the ECO editing mode in the Chip Planner, perform the following steps with the Chip Planner open:

1. On the View menu, click **Layers Settings**. The Layers Setting window appears.
2. Under **Editing Mode**, select **ECO**.

### Creating Atoms

While in the ECO editing mode, the Chip Planner enables you to easily create atoms by moving the mouse pointer over the desired resource atom, right-clicking, and then clicking **Create Atom**. After the atoms are created, the properties can be edited by double-clicking the resource atom, which opens the Resource Property Editor.

The type of atoms that you can create are:

- ALMs (for Arria GX, Stratix III, Stratix II, and Stratix II GX)
- LEs (for Stratix, Stratix GX, Cyclone III, Cyclone II, Cyclone, and MAX II)
- I/O Elements

Creating resource atoms is not supported in the **Assignment** editing mode.

Refer to [“Resource Property Editor” on page 14–21](#) for details about editing atom resource properties.

### Creating ALM Atoms

Each ALM for Stratix III, Stratix II, and Arria GX device families has two combinational LUT outputs and two registered outputs. In the Chip Planner, you can divide each ALM into four resource atoms according to the type of output path. Figure 14–9 shows an ALM as shown in the Chip Planner.

**Figure 14–9. ALM in the Chip Planner**

To create a combinational ALM LUT atom, perform the following steps:

1. Right click on the left side of any unused (not shaded) ALM and click **Create Atom**. The **Resource Selection** dialog box appears.
2. In the **Resource Selection** dialog box, select the atom that you wish to create. The lower index number refers to the top combinational node and the higher index refers to the bottom combinational node.
3. Click **OK**. The **Create <Altera device> LUT Atom** dialog box appears.
4. In the **Atom Name** box, type the name of the resource atom.
5. Under **LUT Mode**, select from **Normal**, **Extended**, or **Arithmetic**.
6. If applicable, in the **Partition** list, select the partition that the newly created atom should reside in. The default partition for newly created atoms is the top-level partition.
7. Click **OK**.

To find more information about the LUT mode, refer to the data sheet of the appropriate device.

When you have successfully created a combinational output, the combinational element is colored in the Chip Planner. Figure 14–10 shows a combinational ALUT atom.

**Figure 14–10. Combinational ALUT Atom**

To create a registered ALM atom, perform the following steps:

1. Right click on any ALM register resource and click **Create Atom**. The **Create Register Atom** dialog box appears.
2. In the **Atom Name** box, type the atom name.
3. Click **OK**.

### *Creating Logic Element Atoms*

The Chip Planner shows resource atoms for Stratix, Cyclone, and MAX device families as logic elements. For Cyclone II devices, the Chip Planner shows resource atoms as the combinational output of the logic element LUT and the registered output of the logic element. [Figure 14–11](#) show an example of an atom resource in the Chip Planner for the Stratix, Cyclone, and MAX devices. [Figure 14–12](#) shows the Cyclone II resource atom in the Chip Planner.

**Figure 14–11. Logic Element for Stratix, Cyclone, and MAX Devices in the Chip Planner**

**Figure 14–12. Logic Element for Cyclone II in the Chip Planner**

To create a logic element resource for Stratix, Cyclone, and MAX device families, perform the following steps:

1. Right-click on any available (unshaded) LE resource and click **Create Atom**. The **Create Logic Cell Atom** dialog box appears.
2. If applicable, in the **Partition** list, select the partition that the newly created atom should reside in. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.
4. Click **OK**.

To create a combinational resource atoms for Cyclone II devices, perform the following steps:

1. Right-click on the left side of an available (unshaded) LE resource and click **Create Atom**. The **Create Cyclone II LUT Atom** dialog box appears.

2. If applicable, in the **Partition** list, select the partition that the newly created atom should reside in. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.
4. Click **OK**.

To create a register resource atom for Cyclone II devices, perform the following steps:

1. Right-click on right side of an available (unshaded) LE resource and click **Create Atom**. The **Create Cyclone II Register Atom** dialog box appears.
2. If applicable, in the **Partition** list, select the partition that the newly created atom should reside in. The default partition for newly created atoms is the top-level partition.
3. In the **Atom Name** box, type the atom name.
4. Click **OK**.

## Deleting Atoms

To delete a resource atoms, right-click on the desired resource atom in the Chip Planner and click **Delete Atom**.

You can delete a resource only after all of its fan-out connections are removed. Protected resources, such as resources in megafunctions or IP cores, cannot be deleted.

Refer to [“Resource Property Editor” on page 14–21](#) for more details about removing fan-out connections.

## Moving Atoms

You can move resource atoms by clicking on the desired resource and dragging the selected atom to a free resource atom. Moving nodes as an ECO can only be done in the ECO editing mode. Changes made while in Assignment mode create location constraints on the design and require a recompilation to incorporate the change.

Resource atoms from protected resources, such as resources of Megafunction IP cores, cannot be moved.

## Check and Save Netlist changes

After making all ECOs, you can run the Fitter to incorporate the changes by clicking on the **Check and Save All Netlist Changes** icon in the Chip Planner toolbar. The Fitter compiles the ECO changes, performs design rule checks on the design, and generates a programming file.

## Resource Property Editor

You can view and edit the following resources with the Resource Property Editor:

- [“Logic Element”](#) (Stratix, Stratix GX, Cyclone III, Cyclone II, Cyclone, and MAX II) on [page 14–21](#)
- [“Adaptive Logic Module”](#) (Arria GX, Stratix II, Stratix II GX, and Stratix III) on [page 14–25](#)
- [“FPGA I/O Elements”](#) (I/O resources) on [page 14–27](#)
- [“PLL Properties”](#) on [page 14–43](#)

You can view (but not edit) the following resources with the Resource Property Editor:

- RAM
- DSP blocks

## Logic Element

An Altera LE contains a four-input LUT, which is a function generator that can implement any function of four variables. In addition, each LE contains a register that is fed by the output of the LUT or by an independent function generated in another LE.

You can use the Resource Property Editor to view and edit any LE in the FPGA. Open the Resource Property Editor for an LE by pointing to **Locate** and clicking **Locate in Resource Property Editor** in one of the following views:

- Timing Closure Floorplan
- RTL Viewer
- Technology Map Viewer
- Node Finder
- Chip Planner

For more information about LE architecture for a particular device family, refer to the device family handbook or data sheet.

You can use the Resource Property Editor to change the following LE properties:

- Data input to the LUT
- LUT mask or LUT equation

*Logic Element Schematic View*

Figure 14–13 shows how the LE appears in the Resource Property Editor.

**Figure 14–13. Stratix LE Architecture** Notes (1), (2)

**Notes to Figure 14–13:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused in gray. For Figure 14–13, the used resources are in blue and the unused resources are in red.
- (2) For more information about the Stratix device’s LE Architecture, refer to the *Stratix Device Handbook*.

## LE Properties

Figure 14–14 shows an example of the properties that can be viewed for a selected LE in the Resource Property Editor. To view LE properties, on the View menu, click **View Properties** to view these properties.

**Figure 14–14. LE Properties**

Properties/Modes	Values	Sum Equation	D & (B # C) # ID & A & IB	Node:	filterfaps_instkn_1[7]
LUT Mask	FC22	Carry Equation	N/A	COMBOUT(0)	REGOUT(0)
Sum LUT Mask	FC22			ACLRI(0)	N/A
Carry LUT Mask	N/A			CLK(0)	N/A
Operation Mode	normal			DATAA(0)	459 ps
Synchronous Mode	on			DATAB(0)	332 ps
Register Cascade Mode	off			DATAD(0)	87 ps
Latch Type	none				

## Modes of Operation

LUTs in an LE can operate in either normal or arithmetic mode.

For more information about LE modes of operation, refer to volume 1 of the appropriate device handbook.

When an LE is configured in normal mode, the LUT in the LE can implement a function of four inputs.

When the LE is configured in arithmetic mode, the LUT in the LE is divided into two 3-input LUTs. The first LUT generates the signal that drives the output of the LUT, while the second LUT generates the carry-out signal. The carry-out signal can only drive a carry-in signal of another LE.

## Sum and Carry Equations

You can change the logic function implemented by the LUT by changing the sum and carry equations. When the LE is configured in normal mode, you can only change the SUM equation. When the LE is configured in arithmetic mode, you can change both the SUM and the CARRY equations.

The LUT mask is the hexadecimal representation of the LUT equation output. When you change the LUT equation, the Quartus II software automatically changes the LUT mask. Conversely, when you change the LUT mask, the Quartus II software automatically computes the LUT equation.

### *sload and sclear Signals*

Each LE register contains a synchronous load (`sload`) signal and a synchronous clear (`sclear`) signal. You can invert either the `sload` or `sclear` signal feeding into the LE. If the design uses the `sload` signal in an LE, the signal and its inversion state must be the same for all other LEs in the same LAB. For example, if two LEs in a LAB have the `sload` signal connected, both LEs must have the `sload` signal set to the same value. This is also true for the `sclear` signal.

### *Register Cascade Mode*

When register cascade mode is enabled, the cascade-in port feeds the input to the register. The register cascade mode is used most often when the design implements shift registers. You can change the register cascade mode by connecting (or disconnecting) the cascade in port. However, if you create this port, you must ensure that the source port LE is directly above the destination LE.

### *Cell Delay Table*

The cell delay table describes the propagation delay from all inputs to all outputs for the selected LE.

### *LE Connections*

On the View menu, click **View Port Connections** to view the connections that feed in and out of an LE. Figure 14–15 shows the LE connections in the Connectivity window.

**Figure 14–15. View Connections**

Input Port name	Signal name	Latch info	Output Port name	Signal name	Latch info
ACLK	filterreset	N/A	COMBOUT	filterfaps:inst1Selector0~14	N/A
ALOAD	<Disconnected>	N/A	COUT	<Disconnected>	N/A
CIN	<Disconnected>	N/A	REGCASCOUT	<Disconnected>	N/A
CLK	filterclk	N/A	REGOUT	filterfaps:instbn_1[7]	N/A
DATAA	filterfaps:instbn[7]	N/A			
DATAB	filterfstate_m:inst1sel[1]	N/A			
DATAD	filterfstate_m:inst1sel[0]	N/A			
EMA	filterfscout	N/A			

### *Delete an LE*

To delete an LE, perform the following steps:

1. Right click the desired LE in the Resource Property Editor, point to Locate and click **Locate in Resource Property Editor**.

2. You must remove all fan-out connections from an LE prior to deletion. To delete fan-out connections, right-click each connected output signal, point to remove, and click **Fanouts**. Select all of the fan-out signals on the dialog box that appear and click **OK**.
3. Remove fan-out connections. After you locate the LE in the Resource Property Editor, delete the fan-out connections. On the right-click menu, point to Remove and click **Fanouts** on all outputs.
4. To delete an atom after all fan-out connections are removed, reference the atom back in the Chip Planner. Right-click and choose **Delete Atom**.

## Adaptive Logic Module

The basic building block of logic in the Arria GX, Stratix II, Stratix II GX, and Stratix III architectures is the ALM. The ALM provides advanced features that have efficient logic utilization. Each ALM contains LUT-based resources that can be divided between two adaptive LUTs (ALUTs). With up to eight inputs to the two ALUTs, each ALM can implement various combinations of two functions. This adaptability allows the ALM to be completely backward-compatible with four-input LUT architectures. One ALM can implement any function with up to six inputs and certain seven-input functions. In addition to the adaptive LUT-based resources, each ALM contains two programmable registers, two dedicated full adders, a carry chain, a shared arithmetic chain, and a register chain. The ALM can efficiently implement various arithmetic functions and shift registers using these dedicated resources.

You can implement the following types of functions in a single ALM:

- Two independent 4-input functions
- An independent 5-input function and an independent 3-input function
- A 5-input function and a 4-input function, if they share one input
- Two 5-input functions, if they share two inputs
- An independent 6-input functions
- Two 6-input functions, if they share four inputs and share function
- Certain 7-input functions

You can use the Resource Property Editor to change the following LE properties:

- Existing ALM atom location
- Data input to the LUT
- LUT mask or LUT equation

## ALM Schematic

You can view and edit any ALM atom with the Resource Property Editor by right-clicking the ALM in the Timing Closure Floorplan, the RTL Viewer, the Node Finder, or the Chip Planner, and clicking **Locate in Resource Property Editor** (Figure 14–16).

For a detailed description of the ALM, refer to the device handbooks for Arria GX, Stratix II, Stratix II GX, or Stratix III device families.

**Figure 14–16. ALM Schematic** *Note (1)*

**Note to Figure 14–16:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused in gray. For Figure 14–16, the used resources are in blue and the unused resources are in red.

## ALM Properties

The properties that you can display for the ALM include an equations table that shows the name and location of each of the two combinational nodes and two register nodes in the ALM, the individual LUT equations for each of the combinational nodes and the `combout`, `sumout`, `carryout`, and `shareout` equations for each combinational node.

### *ALM Connections*

On the View menu, click **View Port Connections** to view the connections that feed in and out of an ALM.

### **FPGA I/O Elements**

Altera FPGAs, with high-performance I/O elements including up to six registers, are equipped with support for a number of I/O standards allowing you to run your design at peak speeds.

For a detailed description of the device I/O elements, refer to the applicable device handbook.

You can change the following I/O properties:

- Delay chain
- Bus hold
- Weak pull up
- Slow slew rate
- I/O standard
- Current strength
- Extend OE disable
- PCI I/O
- Register reset mode
- Register synchronous reset mode
- Register power up
- Register mode

### *Arria GX, Stratix II, Stratix, and Stratix GX I/O Elements*

The I/O elements in Stratix series device families and Arria GX devices contain a bidirectional I/O buffer, six registers, and a latch for a complete bidirectional single data rate or DDR transfer. [Figure 14–17](#) shows the Stratix and Stratix GX I/O element structure. The I/O element structure contains two input registers (plus a latch), two output registers, and two output enable registers.

**Figure 14–17. Stratix and Stratix GX Device I/O Element and Structure** *Notes (1), (2)*

**Notes to Figure 14–17:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–17, the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in Stratix and Stratix GX devices, refer to the *Stratix Device Handbook* and the *Stratix GX Device Handbook*.

Figure 14–18 shows the Arria GX I/O element structures.

**Figure 14–18. Arria GX Device I/O Element and Structure** Notes (1), (2), (3), (4)

**Notes to Figure 14–18:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–18, the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in Stratix II devices, refer to the *Stratix II Device Handbook*.
- (3) This diagram also applies to Stratix II devices.
- (4) Current IOE shown in a DQS pin. Non-DQS pins do not contain DQS delay circuitry.

### Stratix III I/O Elements

The I/O element (IOE) in Stratix III devices contain a bi-directional I/O buffer and I/O registers to support a complete embedded bi-directional single data rate or DDR transfer (shown in Figure 14–19). The IOEs are located in I/O blocks around the periphery of the Stratix III device. The I/O registers are composed of the input path for handling data from the pin to the core, the output path for handling data from the core to the pin, and the output enable (OE) path for handling the OE signal for the output buffer. The output and OE paths are divided into output/OE registers, alignment registers, and HDR blocks. You can bypass each block of the output and output-enable path.

**Figure 14–19. Stratix III Device I/O Element and Structure** *Notes (1), (2)*

**Notes to Figure 14–19:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In [Figure 14–19](#), the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in Stratix III devices, refer to the *Stratix III Device Handbook*.

*Cyclone II and Cyclone I/O Elements*

The I/O elements in Cyclone III, Cyclone II, and Cyclone devices contain a bidirectional I/O buffer and three registers for complete bidirectional single data-rate transfer. [Figure 14–20](#) shows the Cyclone II and Cyclone I/O element structure. The I/O element contains one input register, one output register, and one output enable register.

**Figure 14–20. Cyclone II and Cyclone Device I/O Elements and Structure** Notes (1), (2)

**Notes to Figure 14–20:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–20, the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in Cyclone II and Cyclone devices, refer to the *Cyclone II Device Handbook* and *Cyclone Device Handbook*, respectively.

### Cyclone III I/O Elements

Cyclone III device IOEs contain a bidirectional I/O buffer and five registers for complete embedded bidirectional single-data rate transfer. Figure 14–21 shows the Cyclone III IOE structure. The IOE contains one input register, two output registers, and two output-enable registers. The two output registers and two output-enable registers are utilized for double-data rate (DDR) applications. You can use the input registers for fast setup times and the output registers for fast clock-to-output times. Additionally, you can use the output-enable (OE) registers for fast clock-to-output enable timing. You can use IOEs for input, output, or bidirectional data paths.

Figure 14–21. Cyclone III Device I/O Elements and Structure (1), (2)

**Notes to Figure 14–21:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–21, the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in Cyclone III devices, refer to the *Cyclone III Device Handbook*.

### MAX II I/O Elements

MAX II device I/O elements contain a bidirectional I/O buffer. Figure 14–22 shows the MAX II I/O element structure. Registers from adjacent LABs can drive to or be driven from the I/O element's bidirectional I/O buffers.

**Figure 14–22. MAX II Device I/O Elements and Structure** Notes (1), (2)

**Notes to Figure 14–22:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–22, the used resources are in blue and the unused resources are in red.
- (2) For more information about I/O elements in MAX II devices, refer to the *MAX II Device Handbook*.

### *I/O Element Features in the Resource Property Editor*

You use the Resource Property Editor to view, change connectivity, and edit the properties of the I/O elements. You can use the Chip Planner to change placement, delete, and create new I/O elements. You can perform all these operations on Arria GX, Stratix III, Stratix II, Stratix II GX, Stratix, Stratix GX, Cyclone III, Cyclone II, Cyclone, and MAX II devices.

### **FPGA RAM Blocks**

In the Quartus II software beginning with version 6.1, you can view the architecture of different RAM blocks in the device. Figure 14–23 shows a M9K RAM view in a Stratix III device. You can only view the connections and properties of RAM blocks in the Resource Property Editor.

**Figure 14–24. DSP Block View in a Stratix III Device** *Note (1)***Note to Figure 14–24:**

- (1) By default, the Quartus II software displays the used resources in blue and the unused resources in gray. In Figure 14–24, the used resources are in blue and the unused resources are in red.

## Change Manager

The Change Manager maintains a record of every change that you perform with the Resource Property Editor. Each row in the Change Manager represents one ECO performed. The changes are numbered sequentially, such that the larger the number, the more recent the change.

More complex changes are marked in the Change Manager with a plus icon. You can expand a complex entry in the Change Manager by clicking the plus icon to reveal all the changes that occurred. An example of a complex change is the creation or deletion of an atom.

Table 14–1 summarizes the information shown by the Change Manager.

<i>Table 14–1. Change Manager Information</i>	
Column Name	Description
Index	Identifies, by a sequential number, change records corresponding to changes made in the Chip Planner or Resource Property Editor.  In the case of complex change records, the index column identifies not only the main change, but also any component changes.
Node Name	Uniquely identifies the resource to which a change has been made.
Change Type	Identifies the type of change that has been made to the resource.
Old Value	Lists the value of the resource immediately prior to the change being made.
Target Value	Lists the desired target value (new value) that you have established using the Resource Property Editor, Chip Planner, or SignalProbe.
Current Value	Lists the value of the resource in the netlist that is currently active in memory (as opposed to the value in the netlist saved on disk, which may be different if you have made changes and not yet used the <b>Check &amp; Save All Netlist Changes</b> command).
Disk Value	Lists the current value of the resource on disk.
Comment	Lets you add a comment to a change record in the Change Manager. To add a comment to a change record, double-click in the <b>Comment</b> field of the record you want to annotate, and type the desired comment.

After you complete all of your design modifications, check the integrity of the netlist by right-clicking in the Change Manager and clicking **Check & Save All Netlist Changes**. If the applied changes successfully pass the netlist check, they are written to disk. If the changes do not pass the netlist check, all changes made since the previous successful netlist check are reversed. Figure 14–25 shows the Change Manager.

Colored indicators in the **Current Value** and **Disk Value** columns indicate the present status of the data in those columns. Green in the **Current Value** column indicates that the change has occurred. Blue in the

**Disk Value** column indicates that the change has successfully passed a **Check & Save Netlist Changes** operation. Choose **Check & Save All Netlist Changes**.

**Figure 14–25. Change Manager Results**

Index	Node Name	Change Type	Old Value	Target Value	Current Value	Disk Value
1	test1	SignalProbe	Disconnected	filterInst4	Disconnected	Disconnected
2	mult:inst6lpm_mult:lpm_mult_componentimu...	Modify Source	filtertaps.in...	Disconnected	filtertaps:instxn[4]	filtertaps:instxn[4]
3	mult:inst6lpm_mult:lpm_mult_componentimu...	Modify Source	filtertaps.in...	Disconnected	filtertaps:instxn[4]	filtertaps:instxn[4]
4	taps:instxn_1[4] Feeder.DATAF:0	Modify Source	filtertaps.in...	Disconnected	filtertaps:instxn[4]	filtertaps:instxn[4]
5	mult:inst6lpm_mult:lpm_mult_componentimu...	Modify Source	filtertaps.in...	Disconnected	Disconnected	Disconnected
6	mult:inst6lpm_mult:lpm_mult_componentimu...	Modify Source	filtertaps.in...	Disconnected	Disconnected	Disconnected
7	taps:instxn_1[0] Feeder.DATAF:0	Modify Source	filtertaps.in...	Disconnected	Disconnected	Disconnected

Change Manager: Netlist Check Required -- 3 Pending Changes

For more information about SignalProbe pins, refer to the *Quick Design Debugging Using SignalProbe* chapter in volume 3 of the *Quartus II Handbook*.

Each line in the Change Manager represents a change record. Simple changes appear as a single line. More complex changes, which require that several actions be performed to achieve the change, appear as a single line marked by a plus icon. Click the plus icon to show all the component actions performed as part of the change.

### Complex Changes in the Change Manager

Certain types of changes that you make in the Resource Property Editor or the Chip Planner (including creating or deleting atoms and changing connectivity) may appear to be self-contained, but these changes are actually composed of multiple actions. Complex changes are indicated with a plus icon in the **Index** column.

The change record in the **Change Manager** is a single-line representation of the actual change actions that occurred. You expand the change record to show the component actions that make up the change by clicking the plus icon.

After expanding a change entry in the Change Manager, you can see that creation of an atom consists of three actions:

- The creation of a new logic cell
- The creation of an output port on the newly created logic cell
- The assignment of a location index to the newly created logic cell

You cannot select individual components of a complex change record; if you select any part of a complex change record, the entire complex change record is selected.

For examples of managing changes with the Change Manager, refer to “Example of Managing Changes With the Change Manager” in the Quartus II Help.

## Managing SignalProbe Signals

The SignalProbe pins that you create from the **SignalProbe Pins** dialog box are recorded in the Change Manager. After you have created a SignalProbe assignment, you can use the Change Manager to quickly disable SignalProbe assignments by selecting **Revert to Last Saved Netlist** from the right-click menu in the Change Manager.

For more information about SignalProbe pins, refer to the *Quick Design Debugging Using SignalProbe* chapter in volume 3 of the *Quartus II Handbook*.

## Exporting Changes

You can export all your changes to a tool command language (Tcl) script, a Comma Separated Value (.csv) file, or a Text (.txt) file. The Tcl file enables you to write a script that reapplies changes that were deleted by compilation. You can also write a script that applies to other Quartus II software projects that you create. The Comma-Separated Value or Text files provide a list of changes in a tabular format. To export changes, perform the following steps:

1. On the right-click menu, click **Export Changes**.
2. Specify the Tcl file name.
3. Click **OK**.

The resulting Tcl script can also implement similar changes to another Quartus II design.

## Using Incremental Compilation in the ECO Flow

Beginning with the Quartus II software version 6.1, the incremental compilation feature is turned on by default. The top-level design is automatically set to a design partition when the incremental compilation feature is on. A design partition during incremental compilation can have different netlist types (netlist types can be set to source HDL, post synthesis, or post-fit). The netlist type indicates whether that partition should be resynthesized or refit during the recompilation. Incremental

compilation saves you time and preserves the placement of unchanged partitions in your design if small changes must be made to some partitions late in the design cycle.

For more information about partitions, their netlist types and the Quartus II incremental compilation, refer to the *Quartus Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The behavior of ECOs during an incremental compilation depends on the netlist type of your design partitions. The Quartus II software preserves ECOs if the partition containing the ECO satisfies the following two conditions:

- The netlist type of the affected partition is set to post-fit with the Fitter preservation level set to Placement and Routing.
- There are no source code changes in the affected partition that would cause the partition to be resynthesized during recompilation.

If you have ECOs that affect multiple partitions in your design, the Quartus II software preserves your ECOs during recompilation if any of the affected partitions are set to post-fit. Note that whenever an ECO affects multiple partitions, all of the affected partitions become linked. All of the higher-level “parent” partitions up to their nearest common parent are also linked. In such cases, the connection between the partitions is actually defined outside of the two partitions immediately affected, so all the partitions must be compiled together. The linked partition inherits the netlist type of the partition with the highest level of preservation. For example, if an ECO is performed on a lower-level partition of a post-fit type and a top-level partition of a post-synthesis type, the two partitions will be linked and will have a post-fit netlist type.

If the partitions are set to use the source code or a post-synthesis netlist, the software issues a warning and the post-fit ECO changes are not included in the new compilation.

For example, if your top-level partition netlist type is set to post-synthesis, and either you have no other lower-level partitions or the lower-level partitions netlist type is also set to post-synthesis, during recompilation, your ECOs are not preserved and a warning message appears in the messages window, indicating that ECO modifications are discarded; however, all of the ECO information is retained in the Change Manager. In this case, you can apply ECOs from the change manager and perform the **Check & Save All Netlist Changes** step as described in [““ECO Flow with No Quartus II Incremental Compilation” on page 14–40.](#)

## ECO Flow with No Quartus II Incremental Compilation

If you do not use the Quartus II incremental compilation feature and have implemented ECOs, those ECOs are not preserved during recompilation of your design; however, all of the ECOs remain in the Change Manager. To apply an ECO, right click the Change Manager and click **Apply Selected Change**. (If the Change Manager window is not visible at the bottom of your screen, from the View menu, point to Utility Windows and click **Change Manager**.)

After applying the selected ECO, perform one of the following steps:

- ✓ From the menu within the Change Manager, click **Check & Save All Netlist Changes**.

or

- ✓ From Processing menu, point to Start and click **Start Check & Save All Netlist Changes**.

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. The Tcl commands for controlling the Chip Planner are located in the `chip_planner` package of the `quartus_cdb` executable. A comprehensive list of Tcl commands for the Chip Planner can be found in the *Quartus Scripting Reference Manual*.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## Common ECO Applications

This section provides examples of the situations in which you might use an ECO to make a post-compilation change to your design. To help build your system quickly, you can use Chip Planner functions to perform the following activities:

- Adjust the drive strength of an I/O using the Chip Planner
- Modifying the PLL properties using the Chip Planner (see [page 14–42](#))

## Adjust the Drive Strength of an I/O Using the Chip Planner

To adjust the drive strength of an I/O, follow the steps in this section to run the Fitter and assembler to incorporate the ECO changes into the netlist of the design.

1. In Chip Planner, select the **Post Compilation Editing (ECO)** task.
2. Locate the I/O in the **Resource Property Editor**, as shown in [Figure 14–26](#).

**Figure 14–26. I/O in the Resource Property Editor**

3. Click the **Current Strength** box for the selected I/O, then click **Edit**.
4. Change the value for the desired current strength.
5. Right-click the ECO change in the Change Manager tool and click **Check & Save All Netlist Changes** to apply the ECO change.

Changing the pin locations of input/output ports can be done using the ECOs flow as well. You can drag and move the signal from an existing pin location to a new location while in the Post Compilation Editing (ECO) task in the Chip Planner. Afterward, you can set **Check & Save All Netlist Changes** to compile the ECO.

## Modifying the PLL Properties Using the Chip Planner

PLLs are used to modify and generate clock signals to meet design requirements. Additionally, PLLs are used for distributing clock signals to different devices in a design, reducing clock skew between devices, improving I/O timing, and generating internal clock signals.

The Resource Property Editor enables you to view and modify PLL properties to meet your design requirements. Using the Stratix PLL as an example, the rest of this section describes the adjustable PLL properties and the equations as a function of the adjustable PLL properties that govern the PLL output parameters. [Figure 14-27](#) shows a Stratix PLL as shown in the Resource Property Editor.

Figure 14–27. The PLL View in a Stratix Device

The screenshot shows the Quartus II Resource Property Editor for a PLL. The main window displays a block diagram of the PLL with various input and output ports. Below the diagram are three tables: 'Input Port name' and 'Output Port name', 'Properties/Modes', and 'Properties'.

Input Port name	Signal name	Output Port name	Signal name
SCANDATA	Interactive_Reconfig_pll_reconfig_inst[pll_reconfig_pll]_clk0_79[pll_reconfig_...]	ACTIVECLOCK	<Disconnected>
SCANCLK	Interactive_Reconfig_pll_reconfig_inst[pll_reconfig_pll]_clk0_79[pll_reconfig_...]	CLK 0	Interactive_Reconfig_pll_e_inst[pll_reconfig_inst]_clk0
PPFANA	<Disconnected>	CLK 1	Interactive_Reconfig_pll_e_inst[pll_reconfig_inst]_clk1
		CLK 2	<Disconnected>

Properties/Modes	Values
General PLL Properties	
PLL type	Enhanced
Scan chain	Long
Feedback source	N/A
Compensate clock	clock0
Switchover on loss of clock	N/A
Enable Switch Over Counter	N/A
Switchover counter	N/A
Primary clock	N/A
Input frequency 0 (MHz)	50.00
Input frequency 1 (MHz)	N/A
Nominal VCO frequency (MHz)	593.88
Freq min lock (MHz)	24.99

Properties	Values
CLK 0	
Mult	1
Div	1
Output Frequency (MHz)	50.00
Phase Shift (ps)	0
Delay (ps)	0
Duty Cycle (%)	50
Counter	60
CLK 1	
Mult	1
Div	1
Output Frequency (MHz)	50.00
Phase Shift (ps)	0

SCANACLK	N/A	N/A
SCANCLK	N/A	N/A
SCANDATA	N/A	N/A

## PLL Properties

The Resource Property Editor enables you to modify PLL options, such as phase shift, output clock frequency, and duty cycle. You can also change the following PLL properties with the Resource Property Editor:

- Input frequency
- M VCO tap
- M initial
- M value
- N value
- M counter delay
- N counter delay

- M2 value
- N2 value
- SS counter
- Charge pump current
- Loop filter resistance
- Loop filter capacitance
- Counter delay
- Counter high
- Counter low
- Counter mode
- Initial
- VCO tap

### *Adjusting the Duty Cycle*

Use the following equation to adjust the duty cycle of individual output clocks:

$$(1) \quad \begin{aligned} \text{High \%} &= \text{Counter High} / (\text{Counter High} + \text{Counter Low}) \\ \text{Low \%} &= \text{Counter Low} / (\text{Counter High} + \text{Counter Low}) \end{aligned}$$

### *Adjusting the Phase Shift*

Use the following equation to adjust the phase shift of an output clock of a PLL:

$$(2) \quad \text{Phase Shift} = (\text{Period } V_{CO} \times 0.125 \times \text{Tap } V_{CO}) + (\text{Initial } V_{CO} \times \text{Period } V_{CO})$$

For normal mode Period  $V_{CO}$ , Tap  $V_{CO}$ , and Initial  $V_{CO}$  are governed by the following settings:

$$\begin{aligned} \text{Tap } V_{CO} &= \text{Counter Delay} - M \text{ Tap } V_{CO} \\ \text{Initial } V_{CO} &= \text{Counter Initial} - M \text{ Initial} \\ \text{Period } V_{CO} &= \text{In Clock Period} \times N / M \end{aligned}$$

For external feedback mode, Tap  $V_{CO}$ , Initial  $V_{CO}$ , and Period  $V_{CO}$  are governed by the following settings:

$$\begin{aligned} \text{Tap } V_{CO} &= \text{Counter Delay} - M \text{ Tap } V_{CO} \\ \text{Initial } V_{CO} &= \text{Counter Initial} - M \text{ Initial} \\ \text{Period } V_{CO} &= \text{In Clock Period} \times N / (M + \text{Counter High} + \text{Counter Low}) \end{aligned}$$

For a detailed description of the settings, refer to the Quartus II Help. For more information about Stratix device PLLs, refer to the *Stratix Architecture* chapter in volume 1 of the *Stratix Device Handbook*. For more information about PLLs in Arria GX, Stratix II, Cyclone II, and Cyclone devices, refer to the appropriate device handbook.

### *Adjusting the Output Clock Frequency*

Use the following equation to adjust the PLL output clock in normal mode:

$$(3) \quad \text{Output Clock Frequency} = \text{Input Frequency} \cdot \frac{M_{\text{initial}}}{N_{\text{initial}} + \text{Counter High} + \text{Counter Low}}$$

Use the following equation to adjust the PLL output clock in external feedback mode:

$$(4) \quad \text{OUTCLK} = \text{INCLK} \cdot \frac{M_{\text{initial}} + \text{External Feedback Counter High} + \text{External Feedback Counter Low}}{N_{\text{initial}} + \text{Counter High} + \text{Counter Low}}$$

### *Adjusting the Spread Spectrum*

Use the following equation to adjust the spread spectrum for your PLL:

$$(5) \quad \% \text{spread} = 1 - \frac{M_2 N_1}{M_1 N_2}$$

## Post ECO Steps

This section describes the operations you can perform after making an ECO change with the Chip Planner.

### Performing Static Timing Analysis

After you make an ECO change with the Chip Planner, you must perform static timing analysis of your design with either the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer to ensure that your changes have not adversely affected your design's timing performance.

For example, when you turn on one of the delay chain settings for a specific pin, you change the I/O timing. Therefore, to ensure that all timing requirements are still met, you should perform static timing analysis.

Whenever you change your design using the Chip Planner, Altera also recommends that you perform a gate-level timing simulation on your design with either the Quartus II Simulator or a third-party EDA simulation tool.

For more information about performing a static timing analysis of your design, refer to the Quartus II *Classic Timing Analyzer* or Quartus II *TimeQuest Timing Analyzer* chapters in volume 3 of the Quartus II *Handbook*.

### Generating a Programming File

After you have performed simulation and static timing analysis and are confident that the changes meet your design requirements, generate a new programming file with the Quartus II Assembler. Use the programming file to implement your modified design in an Altera device.

For more information about programming your FPGA, refer to the *Quartus II Programmer* chapter in volume 3 of the *Quartus II Handbook*.

## Conclusion

As the time-to-market pressure mounts, it is more and more important to produce a fully functional design in the shortest amount of time. To address this challenge, Altera developed the Chip Planner in the Quartus II software suite. The Chip Planner enables you to analyze and modify your design floorplan. Also, ECO changes made with the Chip Planner do not require a full recompilation, eliminating the lengthy process of RTL modification, resynthesis, and another place-and-route cycle. In summary, the Chip Planner shortens the verification cycle and brings timing closure to your design in a shorter period of time.

Simulation Coverage Reports .....	1-27
Comparing Two Waveforms .....	1-28
Debugging with the Quartus II Simulator .....	1-29
Breakpoints .....	1-29
Updating Memory Content .....	1-30

Last Simulation Vector Outputs .....	1–30
Conventional Debugging Process .....	1–30
Accessing Internal Signals for Simulation .....	1–30
Scripting Support .....	1–32
Conclusion .....	1–33
Referenced Documents .....	1–33
Document Revision History .....	1–34

## Chapter 2. Mentor Graphics ModelSim Support

Introduction .....	2–1
Background .....	2–1
Software Compatibility .....	2–3
Altera Design Flow with ModelSim or ModelSim-Altera Software .....	2–3
Functional RTL Simulation .....	2–5
Functional Simulation Libraries .....	2–5
lpm Simulation Models .....	2–5
Altera Megafunction Simulation Models .....	2–6
Low-Level Primitive Simulation Models .....	2–7
Simulating VHDL Designs .....	2–7
Create Simulation Libraries .....	2–7
Create Simulation Libraries Using the ModelSim GUI .....	2–8
Create Simulation Libraries Using the ModelSim Command Prompt .....	2–8
Compile Simulation Models into Simulation Libraries .....	2–8
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI .....	2–8
Compile Simulation Models into Simulation Libraries at the ModelSim Command Prompt .....	2–9
Compile Testbench and Design Files into Work Library .....	2–9
Compile Testbench and Design Files into Work Library Using the ModelSim Command Prompt .....	2–9
Loading the Design .....	2–9
Loading the Design Using the ModelSim Command Prompt .....	2–10
Running the Simulation .....	2–10
Running the Simulation Using the ModelSim Command Prompt .....	2–10
Simulating Verilog HDL Designs .....	2–10
Create Simulation Libraries .....	2–10
Create Simulation Libraries Using the ModelSim GUI .....	2–11
Create Simulation Libraries Using the ModelSim Command Prompt .....	2–11
Compile Simulation Models into Simulation Libraries .....	2–11
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI .....	2–11
Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt .....	2–12
Compile Testbench and Design Files into Work Library .....	2–12
Compile Testbench and Design Files into Work Library Using the ModelSim Command Prompt .....	2–12

Loading the Design .....	2-12
Loading a Design Using the ModelSim Command Prompt .....	2-13
Running the Simulation .....	2-13
Running the Simulation Using the ModelSim Command Prompt .....	2-13
Verilog HDL Functional RTL Simulation with Altera Memory Blocks .....	2-13
Post-Synthesis Simulation .....	2-16
Generating a Post-Synthesis Simulation Netlist .....	2-16
Simulating VHDL Designs .....	2-17
Create Simulation Libraries .....	2-17
Create Simulation Libraries Using the ModelSim GUI .....	2-17
Create Simulation Libraries Using the ModelSim Command Prompt .....	2-18
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI ...	2-18
Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt .....	2-18
Compile Testbench and VHDL Output File into Work Library .....	2-18
Compile Testbench and VHDL Output File into Work Library Using ModelSim Command Prompt .....	2-19
Loading the Design .....	2-19
Loading the Design Using the ModelSim Command Prompt .....	2-19
Running the Simulation .....	2-19
Running the Simulation Using the ModelSim Command Prompt .....	2-20
Simulating Verilog HDL Designs .....	2-20
Create Simulation Libraries .....	2-20
Create Simulation Libraries Using the ModelSim GUI .....	2-20
Create Simulation Libraries Using the ModelSim Command Prompt .....	2-20
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI ...	2-21
Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt .....	2-21
Compile Testbench and Verilog Output File into Work Library .....	2-21
Compile Testbench and Verilog Output File into Work Library Using the ModelSim Command Prompt .....	2-21
Loading the Design .....	2-22
Loading the Design Using the ModelSim Command Prompt .....	2-22
Running the Simulation .....	2-22
Running the Simulation Using the ModelSim Command Prompt .....	2-23
Gate-Level Timing Simulation .....	2-23
Generating a Gate-Level Timing Simulation Netlist .....	2-23
Generating a Different Timing Model .....	2-24
Operating Condition Example: Generate All Timing Models for Stratix III Devices	2-25
Perform Timing Simulation Using Post-synthesis Netlist .....	2-26
Gate-Level Simulation Libraries .....	2-27
Simulating VHDL Designs .....	2-29
Create Simulation Libraries .....	2-30
Create Simulation Libraries Using the ModelSim GUI .....	2-30
Create Simulation Libraries Using the ModelSim Command Prompt .....	2-31
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI ...	2-31
Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt .....	2-31

Compile Testbench and VHDL Output File into Work Library .....	2-31
Compile Testbench and VHDL Output File into Work Library Using the ModelSim	
Command Prompt .....	2-32
Loading the Design .....	2-32
Loading a Design Using the ModelSim Command Prompt .....	2-33
Running the Simulation .....	2-33
Running a Simulation Using the ModelSim Command Prompt .....	2-33
Simulating Verilog HDL Designs .....	2-33
Create Simulation Libraries .....	2-33
Create Simulation Libraries Using the ModelSim GUI .....	2-34
Create Simulation Libraries Using the ModelSim Command Prompt .....	2-34
Compile Simulation Models into Simulation Libraries Using the ModelSim GUI ...	2-34
Compile Simulation Models into Simulation Libraries Using the ModelSim Command	
Prompt .....	2-35
Compile Testbench and Verilog Output File into Work Library .....	2-35
Compile Testbench and Verilog Output File into Work Libraries Using the ModelSim	
Command Prompt .....	2-35
Loading the Design .....	2-35
Loading the Design Using the ModelSim Command Prompt .....	2-36
Running the Simulation .....	2-36
Running the Simulation Using the ModelSim Command Prompt .....	2-36
Simulating Designs that Include Transceivers .....	2-37
Stratix GX Functional Simulation .....	2-37
Example: Performing Functional Simulation for Stratix GX in Verilog HDL .....	2-37
Example: Performing Functional Simulation for Stratix GX in VHDL .....	2-37
Stratix GX Post-Fit (Timing) Simulation .....	2-38
Example: Performing Timing Simulation for Stratix GX in Verilog HDL .....	2-38
Example: Performing Timing Simulation for Stratix GX in VHDL .....	2-39
Stratix II GX Functional Simulation .....	2-39
Example: Performing Functional Simulation for Stratix II GX in Verilog HDL .....	2-40
Example: Performing Functional Simulation for Stratix II GX in VHDL .....	2-41
Stratix II GX Post-Fit (Timing) Simulation .....	2-41
Example: Performing Timing Simulation for Stratix II GX in Verilog HDL .....	2-42
Example: Performing Timing Simulation for Stratix II GX in VHDL .....	2-42
Transport Delays .....	2-43
+transport_path_delays .....	2-43
+transport_int_delays .....	2-43
Using the NativeLink Feature with ModelSim .....	2-44
Setting Up NativeLink .....	2-44
Performing an RTL Simulation Using NativeLink .....	2-44
Performing a Gate-Level Simulation Using NativeLink .....	2-47
Setting Up a Testbench .....	2-48
Creating a Testbench .....	2-49
Scripting Support .....	2-50
Generating a Post-Synthesis Simulation Netlist for ModelSim .....	2-50
Tcl Commands .....	2-50
Command Prompt .....	2-50
Generating a Gate-Level Timing Simulation Netlist for ModelSim .....	2-51
Tcl Commands .....	2-51

Command Line .....	2-51
Software Licensing and Licensing Setup .....	2-51
LM_LICENSE_FILE Variable .....	2-52
Conclusion .....	2-52
Referenced Documents .....	2-52
Document Revision History .....	2-53
<b>Chapter 3. Synopsys VCS Support</b>	
Introduction .....	3-1
Software Requirements .....	3-1
Using VCS in the Quartus II Design Flow .....	3-3
Using VCS in the Quartus II Design Flow .....	3-3
Functional Simulations .....	3-4
Megafunctions Requiring Atom Libraries .....	3-5
Functional RTL Simulation with Altera Memory Blocks .....	3-5
Compiling Functional Library Files with Compiler Directives .....	3-5
Post-Synthesis Simulation .....	3-6
Generating a Post-Synthesis Simulation Netlist .....	3-6
Gate-Level Timing Simulation .....	3-8
Generating a Gate-Level Timing Simulation Netlist .....	3-8
Generating Different Timing Model .....	3-9
Operating Condition Example: Generate All Timing Models for Stratix III Devices .....	3-10
Perform Timing Simulation Using Post-Synthesis Netlist .....	3-11
Common VCS Software Compiler Options .....	3-11
Using VirSim .....	3-12
Debugging Support Command-Line Interface .....	3-12
Simulating Designs that Include Transceivers .....	3-13
Stratix GX Functional Simulation .....	3-13
Example of Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL .	
.....	3-13
Stratix GX Post-Fit (Timing) Simulation .....	3-13
Example of Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL .....	
.....	3-14
Stratix II GX Functional Simulation .....	3-14
Example of Compiling Library Files for Functional Stratix II GX Simulation in Verilog HDL	
.....	3-15
Stratix II GX Post-Fit (Timing) Simulation .....	3-16
Example of Compiling Library Files for Timing Stratix II GX Simulation in Verilog HDL ...	
.....	3-16
Using PLI Routines with the VCS Software .....	3-16
Preparing and Linking C Programs to Verilog HDL Code .....	3-16
Transport Delays .....	3-17
+transport_path_delays .....	3-17
+transport_int_delays .....	3-17
Using NativeLink with the VCS Software .....	3-18
Setting Up NativeLink .....	3-18
Performing an RTL Simulation Using NativeLink .....	3-18

Performing a Gate-Level Simulation Using NativeLink .....	3-20
Setting Up a Testbench .....	3-21
Creating a Testbench .....	3-22
Scripting Support .....	3-23
Generating a Post-Synthesis Simulation Netlist for VCS .....	3-23
Tcl Commands .....	3-23
Command Prompt .....	3-23
Generating a Gate-Level Timing Simulation Netlist for VCS .....	3-23
Tcl Commands .....	3-24
Command Prompt .....	3-24
Conclusion .....	3-24
Referenced Documents .....	3-24
Document Revision History .....	3-25

## Chapter 4. Cadence NC-Sim Support

Introduction .....	4-1
Software Requirements .....	4-1
Simulation Flow Overview .....	4-3
Operation Modes .....	4-4
Quartus II Software and NC Simulation Flow Overview .....	4-5
Functional and RTL Simulation .....	4-6
Create Libraries .....	4-6
Basic Library Setup .....	4-7
Using Multiple cds.lib Files .....	4-7
Create a cds.lib File in Command-Line Mode .....	4-8
Create a cds.lib File in GUI Mode .....	4-8
LPM Functions, Altera Megafunctions, and Altera Primitives Libraries .....	4-9
Megafunctions Requiring Atom Libraries .....	4-11
Simulating a Design with Memory .....	4-11
Compile Source Code and Testbenches .....	4-13
Compilation in Command-Line Mode .....	4-13
Compilation in GUI Mode .....	4-14
Elaborate Your Design .....	4-15
Elaboration in Command-Line Mode .....	4-15
Elaboration in GUI Mode .....	4-16
Add Signals to View .....	4-17
Adding Signals in Command-Line Mode .....	4-17
Adding Signals in GUI Mode .....	4-18
Simulate Your Design .....	4-20
Functional/RTL Simulation in Command-Line Mode .....	4-21
Functional/RTL Simulation in GUI Mode .....	4-21
Post-Synthesis Simulation .....	4-22
Quartus II Simulation Output Files .....	4-22
Create Libraries .....	4-23

Compile Project Files and Libraries .....	4-23
Elaborate Your Design .....	4-23
Add Signals to the View .....	4-23
Simulate Your Design .....	4-24
Gate-Level Timing Simulation .....	4-24
Generating a Gate-Level Timing Simulation Netlist .....	4-24
Generating a Different Timing Model .....	4-25
Operating Condition Example: Generate All Timing Models for Stratix III and Cyclone III Devices .....	4-26
Perform Timing Simulation Using Post-Synthesis Netlist .....	4-27
Quartus II Timing Simulation Libraries .....	4-27
Create Libraries .....	4-28
Compile the Project Files and Libraries .....	4-28
Elaborate Your Design .....	4-28
Compiling the Standard Delay Output File (VHDL Only) in Command-Line Mode .....	4-29
Compiling the Standard Delay Output File (VHDL Only) in GUI Mode .....	4-30
Add Signals to View .....	4-30
Simulate Your Design .....	4-31
Simulating Designs that Include Transceivers .....	4-31
Stratix GX Functional Simulation .....	4-31
Example of Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL . .....	4-31
Example of Compiling Library Files for Functional Stratix GX Simulation in VHDL ...	4-31
Stratix GX Post-Fit (Timing) Simulation .....	4-32
Example of Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL .....	4-32
Example of Compiling Library Files for Timing Stratix GX Simulation in VHDL .....	4-32
Stratix II GX Functional Simulation .....	4-33
Example of Compiling Library Files for Functional Stratix II GX Simulation in Verilog HDL .....	4-34
Example of Compiling Library Files for Functional Stratix II GX Simulation in VHDL	4-35
Stratix II GX Post-Fit (Timing) Simulation .....	4-35
Example of Compiling Library Files for Timing Stratix II GX Simulation in Verilog HDL ... .....	4-35
Example of Compiling Library Files for Timing Stratix II GX Simulation in VHDL .....	4-36
Pulse Reject Delays .....	4-36
-PULSE_R .....	4-36
-PULSE_INT_R .....	4-36
Using the NativeLink Feature with NC-Sim .....	4-37
Setting Up NativeLink .....	4-37
Performing an RTL Simulation Using NativeLink .....	4-37
Performing a Gate Level Simulation Using NativeLink .....	4-40
Setting Up a Testbench .....	4-40
Creating a Testbench .....	4-42
Incorporating PLI Routines .....	4-43
Dynamically Link a PLI Library .....	4-43

Dynamically Load a PLI Library .....	4-44
Statically Link the PLI Library with NC-Sim .....	4-47
Scripting Support .....	4-48
Generate NC-Sim Simulation Output Files .....	4-49
Tcl Commands: .....	4-49
Command Prompt .....	4-49
Conclusion .....	4-49
Referenced Documents .....	4-50
Document Revision History .....	4-50

## Chapter 5. Simulating Altera IP in Third-Party Simulation Tools

Introduction .....	5-1
IP Functional Simulation Flow .....	5-1
Verilog and VHDL IP Functional Simulation (IPFS) Models .....	5-2
Instantiate the IP in Your Design .....	5-3
Perform Simulation .....	5-4
Simulating Altera IP Using the Quartus II NativeLink Feature .....	5-4
Set up a Quartus II Project .....	5-5
Select the Third-Party Simulation Tool .....	5-5
Specify the Path for the Third-Party Simulator .....	5-7
Specify the Testbench Settings .....	5-7
Analyze and Elaborate the Quartus II Project .....	5-9
Run RTL Functional Simulation .....	5-9
Simulating Altera IP Without the Quartus II NativeLink Feature .....	5-9
Design Language Examples .....	5-11
Verilog HDL Example: Simulating the IPFS Model in the ModelSim Software .....	5-11
VHDL Example: Simulating the IPFS Model in the ModelSim Software .....	5-12
NC-VHDL Example: Simulating the IPFS Model in the NC-VHDL Software .....	5-14
Verilog HDL Example: Simulating Your IPFS Model in VCS .....	5-15
Single-Step Process .....	5-15
Two-Step Process (Compilation and Simulation) .....	5-16
Conclusion .....	5-16
Referenced Documents .....	5-16
Document Revision History .....	5-17

## Section II. Timing Analysis

### Chapter 6. The Quartus II TimeQuest Timing Analyzer

Introduction .....	6-1
Getting Started with the Quartus II TimeQuest Timing Analyzer .....	6-2
Setting Up the Quartus II TimeQuest Timing Analyzer .....	6-2
Compilation Flow with the Quartus II TimeQuest Timing Analyzer Guidelines .....	6-3
Running the Quartus II TimeQuest Timing Analyzer .....	6-4
Directly from the Quartus II Software .....	6-4
Stand-Alone Mode .....	6-5

Command-Line Mode .....	6-5
Timing Analysis Overview .....	6-7
Clock Analysis .....	6-11
Clock Setup Check .....	6-11
Clock Hold Check .....	6-13
Recovery and Removal .....	6-15
Multicycle Paths .....	6-16
Specify Design Timing Requirements .....	6-19
Create a Timing Netlist .....	6-19
Specify Timing Constraints .....	6-20
Generate SDC Constraint Reports .....	6-21
The Quartus II TimeQuest Timing Analyzer Flow Guidelines .....	6-22
Create a Timing Netlist .....	6-22
Read the Synopsys Design Constraints File .....	6-22
Update Timing Netlist .....	6-23
Generate Timing Reports .....	6-23
Collections .....	6-23
Application Examples .....	6-25
Constraints Files .....	6-25
Fitter and Timing Analysis SDC Files .....	6-26
Specifying SDC Files for Place-and-Route .....	6-26
Specifying SDC Files for Static Timing Analysis .....	6-26
Synopsys Design Constraints File Precedence .....	6-27
Clock Specification .....	6-28
Clocks .....	6-28
Generated Clocks .....	6-29
Virtual Clocks .....	6-32
Multi-Frequency Clocks .....	6-33
Automatic Clock Detection .....	6-34
Derive PLL Clocks .....	6-35
Default Clock Constraints .....	6-37
Clock Groups .....	6-37
Clock Effect Characteristics .....	6-39
Clock Latency .....	6-39
Clock Uncertainty .....	6-40
Derive Clock Uncertainty .....	6-41
Inter-Clock Transfers .....	6-42
Intra-Clock Transfers .....	6-43
I/O Interface Clock Transfers .....	6-43
I/O Specifications .....	6-45
Input and Output Delay .....	6-45
Set Input Delay .....	6-45
Set Output Delay .....	6-47
Timing Exceptions .....	6-48
Precedence .....	6-49
False Path .....	6-49
Minimum Delay .....	6-50

Maximum Delay .....	6-52
Multicycle Path .....	6-53
Clock-as-Data Analysis .....	6-55
Application Examples .....	6-55
Constraint and Exception Removal .....	6-57
Timing Reports .....	6-58
report_timing .....	6-58
report_clock_transfers .....	6-62
report_clocks .....	6-63
report_min_pulse_width .....	6-63
report_net_timing .....	6-65
report_sdc .....	6-66
report_ucp .....	6-66
report_path .....	6-68
report_datasheet .....	6-69
report_rskm .....	6-70
report_tccs .....	6-70
report_path .....	6-71
check_timing .....	6-73
report_clock_fmax_summary .....	6-75
create_timing_summary .....	6-76
Timing Analysis Features .....	6-77
Multi-Corner Analysis .....	6-77
Advanced I/O Timing and Board Trace Model Assignments .....	6-79
Wildcard Assignments and Collections .....	6-79
Resetting a Design .....	6-81
The TimeQuest Timing Analyzer GUI .....	6-82
The Quartus II Software Interface and Options .....	6-83
View Pane .....	6-85
View Pane: Splitting .....	6-85
View Pane: Removing Split Windows .....	6-86
Tasks Pane .....	6-87
Opening a Project and Writing a Synopsys Design Constraints File .....	6-87
Netlist Setup Folder .....	6-88
Reports Folder .....	6-88
Macros Folder .....	6-89
Console Pane .....	6-90
Report Pane .....	6-90
Constraints .....	6-90
Name Finder .....	6-92
Target Pane .....	6-94
SDC Editor .....	6-94
Conclusion .....	6-95
Referenced Documents .....	6-95
Document Revision History .....	6-96

## Chapter 7. Switching to the Quartus II TimeQuest Timing Analyzer

Introduction .....	7-1
Benefits of Switching to the Quartus II TimeQuest Analyzer .....	7-1
Chapter Contents .....	7-2
Switching to the Quartus II TimeQuest Analyzer .....	7-2
Compile Your Design .....	7-2
Create an SDC File .....	7-3
Conversion Utility .....	7-3
Perform Timing Analysis with the Quartus II TimeQuest Timing Analyzer .....	7-4
Run the Quartus II TimeQuest Analyzer .....	7-4
Set the Default Timing Analyzer .....	7-4
Differences Between Quartus II TimeQuest and Quartus II Classic Timing Analyzers .....	7-5
Terminology .....	7-5
Netlist .....	7-6
Collections .....	7-7
Constraints .....	7-7
Constraint Files .....	7-7
Constraint Entry .....	7-8
Time Units .....	7-9
MegaCore Functions .....	7-9
Bus Name Format .....	7-10
Constraint File Priority .....	7-10
Constraint Priority .....	7-11
Ambiguous Constraints .....	7-12
Clocks .....	7-13
Related and Unrelated Clocks .....	7-13
Clock Offset .....	7-14
Clock Latency .....	7-15
Offset and Latency Example .....	7-15
Clock Offset Scenario .....	7-16
Clock Latency Scenario .....	7-17
Clock Uncertainty .....	7-18
Derived and Generated Clocks .....	7-19
Automatic Clock Detection .....	7-19
derive_clocks Command .....	7-20
derive_pll_clocks Command .....	7-22
Hold Relationship .....	7-23
Clock Objects .....	7-23
Hold Multicycle .....	7-24
Fitter Behavior .....	7-27
Fitter Performance .....	7-27
Reporting .....	7-27
Paths and Pairs .....	7-28
Default Reports .....	7-28
Netlist Names .....	7-29
Non-Integer Clock Periods .....	7-29
Other Features .....	7-30

Scripting API .....	7-32
Timing Assignment Conversion .....	7-33
Setup Relationship .....	7-33
Hold Relationship .....	7-34
Clock Latency .....	7-34
Clock Uncertainty .....	7-34
Inverted Clock .....	7-35
Not a Clock .....	7-35
Default Required $f_{MAX}$ Assignment .....	7-35
Virtual Clock Reference .....	7-36
Clock Settings .....	7-37
Multicycle .....	7-37
Clock Enable Multicycle .....	7-38
I/O Constraints .....	7-38
Input and Output Delay .....	7-39
$t_{SU}$ Requirement .....	7-40
$t_H$ Requirement .....	7-43
$t_{CO}$ Requirement .....	7-45
Minimum $t_{CO}$ Requirement .....	7-48
$t_{PD}$ Requirement .....	7-50
Combinational Path Delay Scenario .....	7-50
Minimum $t_{PD}$ Requirement .....	7-51
Cut Timing Path .....	7-52
Maximum Delay .....	7-52
Minimum Delay .....	7-52
Maximum Clock Arrival Skew .....	7-53
Maximum Data Arrival Skew .....	7-53
Constraining Skew on an Output Bus .....	7-53
Conversion Utility .....	7-55
Unsupported Global Assignments .....	7-56
Recommended Global Assignments .....	7-56
Clock Conversion .....	7-58
Instance Assignment Conversion .....	7-59
PLL Phase Shift Conversion .....	7-61
$t_{CO}$ Requirement Conversion .....	7-62
Entity-Specific Assignments .....	7-63
Paths between Unrelated Clock Domains .....	7-63
Unsupported Instance Assignments .....	7-64
Reviewing Conversion Results .....	7-64
Warning Messages .....	7-64
Ignored QSF Variable <assignment> .....	7-65
Global <name> = <value> .....	7-65
QSF: Expected <name> to be set to <expected value> but it is set to <actual value> .....	7-65
QSF: Found Global Fmax Requirement. Translation will be done using derive_clocks ...	7-65
TAN Report Database not found. HDL based assignments will not be migrated ....	7-65

Ignored Entity Assignment (Entity <entity>): <variable> = <value> -from <from> -to <to> .....	7-65
Ignoring OFFSET_FROM_BASE_CLOCK assignment for clock <clock> .....	7-66
Clock <clock> has no FMAX_REQUIREMENT - No clock was generated .....	7-66
No Clock Settings defined in QSF file .....	7-66
Clocks .....	7-66
Clock Transfers .....	7-66
Path Details .....	7-67
Unconstrained Paths .....	7-67
Bus Names .....	7-68
Other .....	7-68
Re-Running the Conversion Utility .....	7-68
Notes .....	7-68
Output Pin Load Assignments .....	7-68
Constraint Target Types .....	7-69
DDR Constraints with the DDR Timing Wizard .....	7-69
HardCopy Stratix Device Handoff .....	7-69
Unsupported SDC Features .....	7-69
Constraint Passing .....	7-70
Optimization .....	7-70
Clock Network Delay Reporting .....	7-70
PowerPlay Power Analysis .....	7-70
Project Management .....	7-71
Conversion Utility .....	7-71
$t_{PD}$ and Minimum $t_{PD}$ Requirement Conversion .....	7-71
Referenced Documents .....	7-72
Document Revision History .....	7-72

## Chapter 8. Quartus II Classic Timing Analyzer

Introduction .....	8-1
Timing Analysis Tool Setup .....	8-2
Static Timing Analysis Overview .....	8-2
Clock Analysis .....	8-4
Clock Setup Check .....	8-4
Clock Hold Check .....	8-6
Multicycle Paths .....	8-7
Clock Settings .....	8-8
Individual Clock Settings .....	8-8
Default Clock Settings .....	8-8
Clock Types .....	8-9
Base Clocks .....	8-9
Derived Clocks .....	8-9
Undefined Clocks .....	8-9
PLL Clocks .....	8-10
Clock Uncertainty .....	8-11
Clock Latency .....	8-12
Timing Exceptions .....	8-15

Multicycle .....	8-15
Destination Multicycle Setup Exception .....	8-15
Destination Multicycle Hold Exception .....	8-16
Source Multicycle Setup Exception .....	8-17
Source Multicycle Hold Exception .....	8-18
Default Hold Multicycle .....	8-19
Clock Enable Multicycle .....	8-19
Setup Relationship and Hold Relationship .....	8-22
Maximum Delay and Minimum Delay .....	8-24
False Paths .....	8-24
I/O Analysis .....	8-26
External Input Delay and Output Delay Assignments .....	8-26
Input Delay Assignment .....	8-26
Output Delay Assignment .....	8-28
Virtual Clocks .....	8-29
Asynchronous Paths .....	8-30
Recovery and Removal .....	8-30
Recovery Report .....	8-31
Removal Report .....	8-32
Skew Management .....	8-34
Maximum Clock Arrival Skew .....	8-34
Maximum Data Arrival Skew .....	8-35
Generating Timing Analysis Reports with report_timing .....	8-36
Other Timing Analyzer Features .....	8-38
Wildcard Assignments .....	8-38
Assignment Groups .....	8-38
Fast Corner Analysis .....	8-40
Early Timing Estimation .....	8-40
Timing Constraint Checker .....	8-41
Latch Analysis .....	8-42
Timing Analysis Using the Quartus II GUI .....	8-43
Assignment Editor .....	8-43
Timing Settings .....	8-44
Clock Settings Dialog Box .....	8-45
More Timing Settings Dialog Box .....	8-46
Timing Reports .....	8-47
Advanced List Path .....	8-49
Early Timing Estimate .....	8-51
Assignment Groups .....	8-51
Scripting Support .....	8-52
Creating Clocks .....	8-53
Base Clocks .....	8-53
Derived Clocks .....	8-53
Clock Latency .....	8-53
Clock Uncertainty .....	8-54
Cut Timing Paths .....	8-54
Input Delay Assignment .....	8-54

Maximum and Minimum Delay .....	8-55
Maximum Clock Arrival Skew .....	8-55
Maximum Data Arrival Skew .....	8-55
Multicycle .....	8-56
Output Delay Assignment .....	8-56
Report Timing .....	8-57
Setup and Hold Relationships .....	8-57
Assignment Group .....	8-57
Virtual Clock .....	8-58
MAX+PLUS II Timing Analysis Methodology .....	8-58
$f_{MAX}$ Relationships .....	8-58
Slack .....	8-58
I/O Timing .....	8-60
$t_{SU}$ Timing .....	8-60
$t_H$ Timing .....	8-60
$t_{CO}$ Timing .....	8-61
Minimum $t_{CO}$ (min $t_{CO}$ ) .....	8-62
$t_{PD}$ Timing .....	8-62
Minimum $t_{PD}$ (min $t_{PD}$ ) .....	8-62
The Timing Analyzer Tool .....	8-62
Conclusion .....	8-63
Referenced Documents .....	8-63
Document Revision History .....	8-64

## Chapter 9. Synopsys PrimeTime Support

Introduction .....	9-1
Quartus II Settings for Generating the PrimeTime Software Files .....	9-2
Files Generated for the PrimeTime Software Environment .....	9-3
The Netlist .....	9-3
The SDO File .....	9-4
Generating Multiple Operating Conditions with TimeQuest .....	9-4
The Tcl Script .....	9-7
Generated File Summary .....	9-9
Running the PrimeTime Software .....	9-10
Analyzing Quartus II Projects .....	9-10
Other pt_shell Commands .....	9-11
PrimeTime Timing Reports .....	9-12
Sample of the PrimeTime Software Timing Report .....	9-12
Comparing Timing Reports from the Quartus II Classic Timing Analyzer and the PrimeTime Software .....	9-13
Clock Setup Relationship and Slack .....	9-13
Clock Hold Relationship and Slack .....	9-17
Input Delay and Output Delay Relationships and Slack .....	9-21
Static Timing Analyzer Differences .....	9-23
The Quartus II Classic Timing Analyzer and the PrimeTime Software .....	9-23
Rise/Fall Support .....	9-23
Minimum and Maximum Delays .....	9-23

Recovery/Removal Analysis .....	9-23
Encrypted Intellectual Property Blocks .....	9-24
Registered Clock Signals .....	9-24
Multiple Source and Destination Register Pairs .....	9-25
Latches .....	9-25
LVDS I/O .....	9-25
Clock Latency .....	9-26
Input and Output Delay Assignments .....	9-26
Generated Clocks Derived from Generated Clocks .....	9-26
The Quartus II TimeQuest Timing Analyzer and the PrimeTime Software .....	9-26
Encrypted Intellectual Property Blocks .....	9-26
Latches .....	9-27
LVDS I/O .....	9-27
The Quartus II TimeQuest Timing Analyzer SDC File and PrimeTime Compatibility .....	9-27
Clock and Data Paths .....	9-27
Inverting and Non-Inverting Propagation .....	9-28
Multiple Rise/Fall Numbers For a Timing Arc .....	9-28
Virtual Generated Clocks .....	9-28
Generated Clocks Derived from Generated Clocks .....	9-28
Conclusion .....	9-28
Referenced Documents .....	9-29
Document Revision History .....	9-30

## Section III. Power Estimation and Analysis

### Chapter 10. PowerPlay Power Analysis

Introduction .....	10-1
Quartus II Early Power Estimator File .....	10-2
PowerPlay Early Power Estimator File Generator Compilation Report .....	10-5
Types of Power Analyses .....	10-6
Factors Affecting Power Consumption .....	10-6
Device Selection .....	10-6
Environmental Conditions .....	10-7
Air Flow .....	10-7
Heat Sink and Thermal Compound .....	10-7
Ambient Temperature .....	10-8
Board Thermal Model .....	10-8
Design Resources .....	10-8
Number, Type, and Loading of I/O Pins .....	10-8
Number and Type of Logic Elements, Multiplier Elements, and RAM Blocks .....	10-8
Number and Type of Global Signals .....	10-9
Signal Activities .....	10-9
PowerPlay Power Analyzer Flow .....	10-10
Operating Conditions .....	10-11
Signal Activities Data Sources .....	10-12

Simulation Results .....	10-13
Using Simulation Files in Modular Design Flows .....	10-15
Complete Design Simulation .....	10-16
Modular Design Simulation .....	10-16
Multiple Simulations on the Same Entity .....	10-17
Overlapping Simulations .....	10-18
Partial Simulations .....	10-18
Node Name Matching Considerations .....	10-18
Glitch Filtering .....	10-19
Node and Entity Assignments .....	10-21
Timing Assignments to Clock Nodes .....	10-22
Default Toggle Rate Assignment .....	10-22
Vectorless Estimation .....	10-23
Using the PowerPlay Power Analyzer .....	10-23
Common Analysis Flows .....	10-23
Signal Activities from Full Post-Fit Netlist (Timing) Simulation .....	10-23
Signal Activities from RTL (Functional) Simulation, Supplemented by Vectorless Estimation .....	10-24
Signal Activities from Vectorless Estimation, User-Supplied Input Pin Activities .....	10-24
Signal Activities from User Defaults Only .....	10-24
Generating a SAF or VCD File Using the Quartus II Simulator .....	10-24
Generating a VCD File Using a Third-Party Simulator .....	10-28
Running the PowerPlay Power Analyzer Using the Quartus II GUI .....	10-31
PowerPlay Power Analyzer Compilation Report .....	10-39
Summary .....	10-39
Settings .....	10-39
Simulation Files Read .....	10-39
Operating Conditions Used .....	10-39
Thermal Power Dissipated by Block .....	10-39
Thermal Power Dissipation by Block Type (Device Resource Type) .....	10-39
Thermal Power Dissipation by Hierarchy .....	10-40
Core Dynamic Thermal Power Dissipation by Clock Domain .....	10-40
Current Drawn from Voltage Supplies .....	10-40
Confidence Metric Details .....	10-40
Signal Activities .....	10-41
Messages .....	10-41
Specific Rules for Reporting .....	10-41
Scripting Support .....	10-41
Running the PowerPlay Power Analyzer from the Command Line .....	10-42
Conclusion .....	10-43
Referenced Documents .....	10-43
Document Revision History .....	10-44

## Section IV. Signal Integrity

### Chapter 11. Signal Integrity Analysis with Third-Party Tools

Introduction .....	11-1
The Need for FPGA to Board Signal Integrity Analysis .....	11-3
The Double Counting Problem for FPGA Output Timing .....	11-4
Defining the Double Counting Problem .....	11-4
The Solution to Double Counting .....	11-5
I/O Model Selection: IBIS or HSPICE .....	11-7
FPGA to Board Signal Integrity Analysis Flow .....	11-8
Create I/O and Board Trace Model Assignments .....	11-10
Enable Output File Generation .....	11-10
Generate the Output Files .....	11-10
Customize the Output Files .....	11-11
Set Up and Run Simulations in Third-Party Tools .....	11-11
Interpret Simulation Results .....	11-12
Simulation with IBIS Models .....	11-12
Elements of an IBIS Model .....	11-12
Creating Accurate IBIS Models .....	11-13
Download IBIS Models .....	11-13
Generate Custom IBIS Models with the IBIS Writer .....	11-14
Design Simulation Using the Mentor Graphics HyperLynx Software .....	11-17
Configuring LineSim to Use Altera IBIS Models .....	11-20
Integrating Altera IBIS Models into LineSim Simulations .....	11-21
Running and Interpreting LineSim Simulations .....	11-24
Simulation with HSPICE Models .....	11-25
Supported Devices and Signaling .....	11-26
Creating Accurate HSPICE Models .....	11-26
Creating HSPICE Model Files Using the Quartus II GUI .....	11-27
Creating HSPICE Model Files Using Tcl Scripting and the Command Line .....	11-28
Customizing HSPICE Model Files .....	11-29
Design Simulation Using Synopsys HSPICE .....	11-30
Running HSPICE Simulations .....	11-30
Viewing and Interpreting Tabular Simulation Results .....	11-31
Viewing Graphical Simulation Results .....	11-31
Making Design Adjustments Based on HSPICE Simulations .....	11-33
Conclusion .....	11-35
Referenced Documents .....	11-36
Document Revision History .....	11-36

## Section V. In-System Design Debugging

### Chapter 12. Quick Design Debugging Using SignalProbe

Introduction .....	12-1
--------------------	------

On-Chip Debugging Tool Comparison .....	12-2
Debugging Using the SignalProbe Feature .....	12-4
Reserve the SignalProbe Pins .....	12-4
Perform a Full Compilation .....	12-6
Assign a SignalProbe Source .....	12-6
Add Registers to the Pipeline Path to SignalProbe Pin .....	12-7
Perform a SignalProbe Compilation .....	12-9
Analyze the Results of the SignalProbe Compilation .....	12-10
Generate the Programming File .....	12-11
SignalProbe ECO flows .....	12-11
SignalProbe ECO Flow with Quartus II Incremental Compilation .....	12-11
SignalProbe ECO Flow without Quartus Incremental Compilation .....	12-12
Common Questions About the SignalProbe Feature .....	12-14
Why Did I Get the Following Error Message, "Error: There are No Enabled SignalProbes to Process"?	12-14
How Can I Retain My SignalProbe ECOs during Re-compilation of My Design? .....	12-14
Why Did My SignalProbe Source Disappear in the Change Manager? .....	12-14
What is an ECO and Where Can I Find More Information on ECO? .....	12-15
How Do I Migrate My Previous SignalProbe Assignments in the Quartus II Software Versions 5.1 and below to Versions 6.0 and Higher? .....	12-15
What are all the Changes for the SignalProbe Feature between the Quartus II Software Version 5.1 and Earlier, and Version 6.0 and Later? .....	12-16
Scripting Support .....	12-17
Make a SignalProbe Pin .....	12-17
Delete a SignalProbe Pin .....	12-17
Enable a SignalProbe Pin .....	12-18
Disable a SignalProbe Pin .....	12-18
Perform a SignalProbe Compilation .....	12-18
Migrating Previous SignalProbe Pins to the Quartus II Software Versions 6.0 and Later .....	12-18
Script Example .....	12-18
Using SignalProbe with the APEX Device Family .....	12-19
Adding SignalProbe Sources .....	12-19
Performing a SignalProbe Compilation .....	12-20
Running SignalProbe with Smart Compilation .....	12-21
Understanding the Results of a SignalProbe Compilation .....	12-21
Analyzing SignalProbe Routing Failures .....	12-23
SignalProbe Scripting Support for APEX Devices .....	12-23
Reserving SignalProbe Pins .....	12-24
Adding SignalProbe Sources .....	12-24
Assigning I/O Standards .....	12-24
Adding Registers for Pipelining .....	12-24
Run SignalProbe Automatically .....	12-25
Run SignalProbe Manually .....	12-25
Enable or Disable All SignalProbe Routing .....	12-25
Running SignalProbe with Smart Compilation .....	12-26
Allow SignalProbe to Modify Fitting Results .....	12-26

Conclusion .....	12–26
Referenced Documents .....	12–26
Document Revision History .....	12–27

## Chapter 13. Design Debugging Using the SignalTap II Embedded Logic Analyzer

Introduction .....	13–1
Hardware and Software Requirements .....	13–3
On-Chip Debugging Tool Comparison .....	13–5
Design Flow Using the SignalTap II Logic Analyzer .....	13–7
SignalTap II Logic Analyzer Task Flow .....	13–8
Add the SignalTap II Logic Analyzer to Your Design .....	13–9
Configure the SignalTap II Logic Analyzer .....	13–9
Define Triggers .....	13–9
Compile the Design .....	13–9
Program the Target Device or Devices .....	13–9
Run the SignalTap II Logic Analyzer .....	13–10
View, Analyze, and Use Captured Data .....	13–10
Add the SignalTap II Logic Analyzer to Your Design .....	13–10
Creating and Enabling a SignalTap II File .....	13–10
Creating a SignalTap II File .....	13–10
Enabling and Disabling a SignalTap II File for the Current Project .....	13–11
Using the MegaWizard Plug-In Manager to Create Your Embedded Logic Analyzer .....	13–12
Creating an HDL Representation Using the MegaWizard Plug-In Manager .....	13–12
SignalTap II Megafunction Ports .....	13–16
Instantiating the SignalTap II Logic Analyzer in Your HDL .....	13–16
Embedding Multiple Analyzers in One FPGA .....	13–17
Monitoring FPGA Resources Used by the SignalTap II Logic Analyzer .....	13–17
Configure the SignalTap II Logic Analyzer .....	13–18
Assigning an Acquisition Clock .....	13–18
Adding Signals to the SignalTap II File .....	13–19
Signal Preservation .....	13–21
Assigning Data Signals .....	13–22
Node List Signal Use Options .....	13–23
Untappable Signals .....	13–23
Adding Signals with a Plug-In .....	13–23
Specifying the Sample Depth .....	13–25
Capturing Data to a Specific RAM Type .....	13–26
Choosing the Buffer Acquisition Mode .....	13–26
Circular Buffer .....	13–27
Segmented Buffer .....	13–27
Managing Multiple SignalTap II Files and Configurations .....	13–28
Define Triggers .....	13–30
Creating Basic Trigger Conditions .....	13–30
Creating Advanced Trigger Conditions .....	13–31
Examples of Advanced Triggering Expressions .....	13–32
Trigger Condition Flow Control .....	13–34
Sequential Triggering .....	13–34

Custom State-Based Triggering .....	13–36
State Diagram Pane .....	13–39
State Machine Pane .....	13–39
Resources Pane .....	13–39
SignalTap II Trigger Flow Description Language .....	13–40
State Labels .....	13–41
Boolean_expression .....	13–41
Action_list .....	13–42
Resource Manipulation Action .....	13–43
Buffer Control Action .....	13–43
State Transition Action .....	13–44
Specifying the Trigger Position .....	13–44
Creating a Power-Up Trigger .....	13–45
Enabling a Power-Up Trigger .....	13–45
Managing and Configuring Power-Up and Runtime Trigger Conditions .....	13–46
Using External Triggers .....	13–47
Trigger In .....	13–47
Trigger Out .....	13–48
Using the Trigger Out of One Analyzer as the Trigger In of Another Analyzer .....	13–48
Compile the Design .....	13–50
Faster Compilations with Quartus II Incremental Compilation .....	13–51
Enabling Incremental Compilation for your Design .....	13–51
Using Incremental Compilation with the SignalTap II Logic Analyzer .....	13–52
Preventing Changes Requiring Recompilation .....	13–54
Timing Preservation with the SignalTap II Logic Analyzer .....	13–54
Performance and Resource Considerations .....	13–55
Program the Target Device or Devices .....	13–57
Programming a Single Device .....	13–57
Programming Multiple Devices to Debug Multiple Designs .....	13–58
Run the SignalTap II Logic Analyzer .....	13–59
Running with a Power-Up Trigger .....	13–60
Running with Runtime Triggers .....	13–60
Performing a Force Trigger .....	13–61
SignalTap II Status Messages .....	13–62
View, Analyze, and Use Captured Data .....	13–63
Viewing Captured Data .....	13–63
Creating Mnemonics for Bit Patterns .....	13–64
Automatic Mnemonics with a Plug-In .....	13–64
Locating a Node in the Design .....	13–65
Saving Captured Data .....	13–66
Converting Captured Data to Other File Formats .....	13–66
Creating a SignalTap II List File .....	13–67
Other Features .....	13–67
Using the SignalTap II MATLAB MEX Function to Capture Data .....	13–67
Using SignalTap II in a Lab Environment .....	13–69
Remote Debugging Using the SignalTap II Logic Analyzer .....	13–69
Equipment Setup .....	13–70

Software Setup on the Remote PC .....	13-70
Software Setup on the Local PC .....	13-71
SignalTap II Setup on the Local PC .....	13-72
SignalTap II Scripting Support .....	13-72
SignalTap II Command Line Options .....	13-73
SignalTap II Tcl Commands .....	13-75
Design Example: Using SignalTap II Logic Analyzers in SOPC Builder Systems .....	13-77
Custom Triggering Flow Application Examples .....	13-77
Design Example 1: Specifying a Custom Trigger Position .....	13-77
Design Example 2: Trigger When triggercond1 Occurs Ten Times between triggercond2 and triggercond3 .....	13-78
Conclusion .....	13-80
Referenced Documents .....	13-80
Document Revision History .....	13-81

## Chapter 14. In-System Debugging Using External Logic Analyzers

Introduction .....	14-1
Choosing a Logic Analyzer .....	14-2
Required Components .....	14-3
FPGA Device Support .....	14-3
Debugging Your Design Using the Logic Analyzer Interface .....	14-4
Creating a Logic Analyzer Interface File .....	14-4
Creating a New Logic Analyzer Interface File .....	14-5
Opening an Existing External Analyzer Interface File .....	14-6
Saving the External Analyzer Interface File .....	14-7
Configuring the Logic Analyzer Interface File Core Parameters .....	14-7
Mapping the Logic Analyzer Interface File Pins to Available I/O Pins .....	14-9
Mapping Internal Signals to the Logic Analyzer Interface Banks .....	14-9
Using the Node Finder .....	14-10
Enabling the Logic Analyzer Interface Before Compiling Your Quartus II Project .....	14-11
Compiling Your Quartus II Project .....	14-12
Programming Your FPGA Using the Logic Analyzer Interface .....	14-13
Using the Logic Analyzer Interface with Multiple Devices .....	14-14
Configuring Banks in the Logic Analyzer Interface File .....	14-15
Acquiring Data on Your Logic Analyzer .....	14-15
Advanced Features .....	14-15
Using the Logic Analyzer Interface with Incremental Compilation .....	14-15
Creating Multiple Logic Analyzer Interface Instances in One FPGA .....	14-16
Conclusion .....	14-17
Document Revision History .....	14-18

## Chapter 15. In-System Updating of Memory and Constants

Introduction .....	15-1
Overview .....	15-1
Device Megafunction Support .....	15-2
Using In-System Updating of Memory Constants with Your Design .....	15-3
Creating In-System Modifiable Memories Constants .....	15-3

Running the In-System Memory Content Editor .....	15-4
Instance Manager .....	15-5
Editing Data Displayed in the Hex Editor .....	15-7
Importing Exporting Memory Files .....	15-7
Viewing Memories Constants in the Hex Editor .....	15-7
Scripting Support .....	15-9
Programming the Device Using the In-System Memory Content Editor .....	15-10
Example: Using the In-System Memory Content Editor with the SignalTap II Embedded Logic Analyzer .....	15-10
Conclusion .....	15-11
Referenced Documents .....	15-11
Document Revision History .....	15-12
<b>Chapter 16. Design Debugging Using In-System Sources and Probes</b>	
Introduction .....	16-1
Overview .....	16-1
Hardware and Software Requirements .....	16-3
Design Flow Using In-System Sources and Probes .....	16-4
Configuring the <code>altsource_probes</code> Megafunction .....	16-6
Instantiating the <code>altsource_probe</code> Megafunction .....	16-8
Compiling the Design .....	16-8
Running the	
In-System Sources and Probes Editor .....	16-9
Programming Your Device Using the JTAG Chain Configuration Window .....	16-11
Instance Manager .....	16-12
Sources and Probes Editor Window .....	16-13
Reading Probe Data .....	16-13
Writing Data .....	16-13
Data Organization .....	16-14
TCL Support .....	16-14
Design Example: Dynamic PLL Reconfiguration .....	16-18
Conclusion .....	16-21
Referenced Documents .....	16-21
Document Revision History .....	16-21

## Section VI. Formal Verification

### Chapter 17. Cadence Encounter Conformal Support

Introduction .....	17-1
Formal Verification Versus Simulation .....	17-2
Formal Verification: What You Need to Know .....	17-2
Formal Verification Design Flow .....	17-2
Quartus II Integrated Synthesis .....	17-3
EDA Tool Support for Quartus II Integrated Synthesis .....	17-3
Synplify Pro .....	17-3

EDA Tool Support for Synplify Pro .....	17-4
RTL Coding Guidelines for Quartus II Integrated Synthesis .....	17-5
Synthesis Directives and Attributes .....	17-5
Stuck-at Registers .....	17-7
ROM, LPM_DIVIDE, and Shift Register Inference .....	17-8
RAM Inference .....	17-8
Latch Inference .....	17-9
Combinational Loops .....	17-9
Finite State Machine Coding Styles .....	17-10
Generating the Post-Fit Netlist Output File and the Encounter Conformal Setup Files .....	17-10
Tcl Command .....	17-15
GUI .....	17-15
The Quartus II Software Generated Files, Formal Verification Scripts, and Directories ...	17-16
Understanding the Formal Verification Scripts for Encounter Conformal .....	17-18
The Encounter Conformal Commands within the Quartus II Software-Generated Scripts .....	17-18
Comparing Designs Using Encounter Conformal .....	17-21
Black Boxes in the Encounter Conformal Flow .....	17-21
Running the Encounter Conformal Software .....	17-22
Running the Encounter Conformal Software from the GUI .....	17-22
Running the Encounter Conformal Software From a System Command Prompt .....	17-24
Known Issues and Limitations .....	17-24
Conclusion .....	17-27
Black Box Models .....	17-28
Conformal Dofile/Script Example .....	17-30
Referenced Documents .....	17-32
Document Revision History .....	17-33

## Chapter 18. Synopsys Formality Support

Introduction .....	18-1
Formal Verification .....	18-1
Equivalence Checking .....	18-1
Formal Verification Support .....	18-2
EDA Tools and Device Support .....	18-2
Formal Verification Between RTL and Post-Synthesis Netlist .....	18-2
Generating Post-Synthesis Netlist for Formal Verification .....	18-3
DC FPGA Software Settings .....	18-3
Generating the VO File and Formality Script .....	18-4
Handling Black Boxes .....	18-9
Tcl Command .....	18-9
GUI .....	18-10
Quartus II Scripts for Formality .....	18-11
Comparing Designs Using the Formality Software .....	18-11
Known Issues and Limitations .....	18-12
Conclusion .....	18-12
Related Links .....	18-12
Tcl Sample Script .....	18-13

DC FPGA Synthesis Script .....	18–13
Quartus II Software-Generated Formal Verification Script .....	18–14
Referenced Documents .....	18–15
Document Revision History .....	18–15

## Section VII. Device Programming

### Chapter 19. Quartus II Programmer

Introduction .....	19–1
Programming Flow .....	19–1
Programming and Configuration Modes .....	19–4
JTAG Mode .....	19–4
Passive Serial Mode .....	19–4
Active Serial Mode .....	19–5
In-Socket Programming Mode .....	19–5
Programmer Overview .....	19–6
Tools Menu .....	19–11
Hardware Setup .....	19–12
Hardware Settings .....	19–12
JTAG Settings .....	19–13
Device Programming and Configuration .....	19–14
Single Device Programming and Configuration .....	19–14
Multi-Device Programming and Configuration .....	19–14
Bypassing an Altera Device .....	19–15
Bypassing a Non-Altera Device .....	19–15
Chain Description File .....	19–17
Design Security Key Programming .....	19–17
Optional Programming Files .....	19–18
Types of Programming and Configuration Files .....	19–18
Generating Optional Programming Files .....	19–20
Create Programming Files .....	19–20
Convert Programming Files .....	19–20
Generating Optional Programming or Configuration Files During Compilation .....	19–21
Flash Loaders .....	19–21
Parallel Flash Loader .....	19–21
Serial Flash Loader .....	19–21
Other Programming Tools .....	19–22
Quartus II Stand-Alone Programmer .....	19–22
jtagconfig Debugging Tool .....	19–22
Scripting Support .....	19–22
Conclusion .....	19–23
Referenced Documents .....	19–24
Document Revision History .....	19–24

# Chapter Revision Dates

The chapters in this book, the Quartus II Handbook, Volume 3, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

Chapter 1. Quartus II Simulator

Revised: *October 2007*  
Part number: *QII53017-7.2.0*

Chapter 2. Mentor Graphics ModelSim Support

Revised: *October 2007*  
Part number: *QII53001-7.2.0*

Chapter 3. Synopsys VCS Support

Revised: *October 2007*  
Part number: *QII53002-7.2.0*

Chapter 4. Cadence NC-Sim Support

Revised: *October 2007*  
Part number: *QII53003-7.2.0*

Chapter 5. Simulating Altera IP in Third-Party Simulation Tools

Revised: *October 2007*  
Part number: *QII53014-7.2.0*

Chapter 6. The Quartus II TimeQuest Timing Analyzer

Revised: *October 2007*  
Part number: *QII53018-7.2.0*

Chapter 7. Switching to the Quartus II TimeQuest Timing Analyzer

Revised: *October 2007*  
Part number: *QII53019-7.2.0*

Chapter 8. Quartus II Classic Timing Analyzer

Revised: *October 2007*  
Part number: *QII53004-7.2.0*

Chapter 9. Synopsys PrimeTime Support

Revised: *October 2007*  
Part number: *QII53005-7.2.0*

- Chapter 10. PowerPlay Power Analysis  
Revised: *October 2007*  
Part number: *QII53013-7.2.0*
- Chapter 11. Signal Integrity Analysis with Third-Party Tools  
Revised: *October 2007*  
Part number: *QII53020-7.2.0*
- Chapter 12. Quick Design Debugging Using SignalProbe  
Revised: *October 2007*  
Part number: *QII53008-7.2.0*
- Chapter 13. Design Debugging Using the SignalTap II Embedded Logic Analyzer  
Revised: *October 2007*  
Part number: *QII53009-7.2.0*
- Chapter 14. In-System Debugging Using External Logic Analyzers  
Revised: *October 2007*  
Part number: *QII53016-7.2.0*
- Chapter 15. In-System Updating of Memory and Constants  
Revised: *October 2007*  
Part number: *QII53012-7.2.0*
- Chapter 16. Design Debugging Using In-System Sources and Probes  
Revised: *October 2007*  
Part number: *QII53021-7.2.0*
- Chapter 17. Cadence Encounter Conformal Support  
Revised: *October 2007*  
Part number: *QII53011-7.2.0*
- Chapter 18. Synopsys Formality Support  
Revised: *October 2007*  
Part number: *QII53015-7.2.0*
- Chapter 19. Quartus II Programmer  
Revised: *October 2007*  
Part number: *QII53022-7.2.0*

# About this Handbook

This handbook provides comprehensive information about the Altera® Quartus® II design software, version 7.2.

## How to Contact Altera

For the most up-to-date information about Altera products, refer to the following table.

Information Type	Contact (1)
Technical support	<a href="http://www.altera.com/mysupport/">www.altera.com/mysupport/</a>
Technical training	<a href="http://www.altera.com/training/custrain@altera.com">www.altera.com/training/custrain@altera.com</a>
Product literature	<a href="http://www.altera.com/literature/">www.altera.com/literature/</a>
Altera literature services	<a href="mailto:literature@altera.com">literature@altera.com (1)</a>
FTP site	<a href="ftp.altera.com">ftp.altera.com</a>

**Note to table:**

(1) You can also contact your local Altera sales office or sales representative.

## Third-Party Software Product Information

Third-party software products described in this handbook are not Altera products, are licensed by Altera from third parties, and are subject to change without notice. Updates to these third-party software products may not be concurrent with Quartus II software releases. Altera has assumed responsibility for the selection of such third-party software products and its use in the Quartus II 7.2 software release. To the extent that the software products described in this handbook are derived from third-party software, no third party warrants the software, assumes any liability regarding use of the software, or undertakes to furnish you any support or information relating to the software. EXCEPT AS EXPRESSLY SET FORTH IN THE APPLICABLE ALTERA PROGRAM LICENSE SUBSCRIPTION AGREEMENT UNDER WHICH THIS SOFTWARE WAS PROVIDED TO YOU, ALTERA AND THIRD-PARTY LICENSORS DISCLAIM ALL WARRANTIES WITH RESPECT TO THE USE OF SUCH THIRD-PARTY SOFTWARE CODE OR DOCUMENTATION IN THE SOFTWARE, INCLUDING, WITHOUT LIMITATION, ANY WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE, TITLE, AND NONINFRINGEMENT. For more information, including the latest available version of specific third-party software products, refer to the documentation for the software in question.

# Typographic Conventions

This document uses the typographic conventions shown below.

Visual Cue	Meaning
<b>Bold Type with Initial Capital Letters</b>	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: <b>Save As</b> dialog box.
<b>bold type</b>	External timing parameters, directory names, project names, disk drive names, filenames, filename extensions, and software utility names are shown in bold type. Examples: <b>f<sub>MAX</sub></b> , <b>lqdesigns</b> directory, <b>d:</b> drive, <b>chiptrip.gdf</b> file.
<i>Italic Type with Initial Capital Letters</i>	Document titles are shown in italic type with initial capital letters. Example: <i>AN 75: High-Speed Board Design</i> .
<i>Italic type</i>	Internal timing parameters and variables are shown in italic type. Examples: <i>t<sub>PIA</sub></i> , <i>n + 1</i> .  Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: <file name>, <project name>.pof file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
“Subheading Title”	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: “Typographic Conventions.”
Courier type	Signal and port names are shown in lowercase Courier type. Examples: data1, tdi, input. Active-low signals are denoted by suffix n, e.g., resetn.  Anything that must be typed exactly as it appears is shown in Courier type. For example: c:\qdesigns\tutorial\chiptrip.gdf. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword SUBDESIGN), as well as logic function names (e.g., TRI) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
✓, —, N/A	Used in table cells to indicate the following: ✓ indicates a “Yes” or “Applicable” statement; — indicates a “No” or “Not Supported” statement; N/A indicates that the table cell entry is not applicable to the item of interest.
■ ● ●	Bullets are used in a list of items when the sequence of the items is not important.
✓	The checkmark indicates a procedure that consists of one step only.
	The hand points to information that requires special attention.
	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
	A warning calls attention to a condition or possible situation that can cause injury to the user.
↵	The angled arrow indicates you should press the Enter key.
	The feet direct you to more information on a particular topic.

As the design complexity of FPGAs continues to rise, verification engineers are finding it increasingly difficult to simulate their system-on-a-programmable-chip (SOPC) designs in a timely manner. The verification process is now the bottleneck in the FPGA design flow. You can perform functional and timing simulation of your design by using the Quartus® II Simulator. The Quartus II software also provides a wide range of features for performing simulation of designs in EDA simulation tools.

This section includes the following chapters:

- [Chapter 1, Quartus II Simulator](#)
- [Chapter 2, Mentor Graphics ModelSim Support](#)
- [Chapter 3, Synopsys VCS Support](#)
- [Chapter 4, Cadence NC-Sim Support](#)
- [Chapter 5, Simulating Altera IP in Third-Party Simulation Tools](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

With today's FPGAs becoming faster and more complex, designers face challenges in validating their designs. Simulation verifies the correctness of the design, reducing board testing and debugging time.

Altera® offers the Simulator as part of the Quartus® II software to assist designers with design verification. The Quartus II Simulator has a comprehensive set of features that are covered in the following sections:

- "Simulation Flow"
- "Waveform Editor" on page 1-5
- "Simulator Settings" on page 1-17
- "Simulation Report" on page 1-25
- "Debugging with the Quartus II Simulator" on page 1-29
- "Scripting Support" on page 1-32

This chapter describes how to perform different types of simulations with the Quartus II Simulator.

## Simulation Flow

You can perform both functional and timing simulations with the Quartus II Simulator. Both types of simulation verify the correctness and behavior of your design. Functional simulations are run at the beginning of the Quartus II design flow and timing simulations are run at the end.

Figure 1-1 shows the Quartus II Simulator flow.

Figure 1-1. Simulation Flow

Notes to Figure 1-1:

- (1) For more information on EDA Simulators, refer to the *Simulation* section in volume 3 of the *Quartus II Handbook*.
- (2) You can use Signal Activity Files (.saf) or Value Change Dump Files (.vcd) in the PowerPlay Power Analyzer to check power resources.

As shown in [Figure 1-1](#), your design simulation can happen at the functional level, where your design's logical behavior is verified and no timing information is used in simulation. Timing simulation can happen after your design has been compiled (synthesized and placed and routed) and after you use the timing data of your design's resources. In Timing simulation, your design's logical behavior is verified with the device's worst-case timing models. Timing simulation using the Fast Timing Model is also a type of Timing simulation where best-case timing data is used.

To perform functional simulations with the Quartus II Simulator, you must first generate a functional simulation netlist. A functional netlist file is a flattened netlist extracted from the design files that does not contain timing information.

For timing simulations, you must first perform place-and-route and static timing analysis to generate a timing simulation netlist. A timing simulation netlist includes timing delays of each device atom block and the routing delays.

If you want to use third-party EDA simulation tools, you can generate a netlist using EDA Netlist Writer. You can use this netlist with your testbench files in third-party simulation tools.

For more information about third-party simulators, refer to the respective EDA Simulation chapter in the *Simulation* section in volume 3 of the *Quartus II Handbook*.

The Quartus II Simulator supports Functional, Timing, and Timing using Fast Timing Model simulations. The following sections describe how to perform these simulations.

## Functional Simulation

To run a functional simulation, perform the following steps:

1. On the Processing menu, click **Generate Functional Simulation Netlist**. This flattens the functional simulation netlist extracted from the design files. The netlist does not contain timing information.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
4. In the **Simulation mode** list, select **Functional**.

5. In the **Simulation input** box, specify the vector source. You must specify the vector file to run the simulation.
6. Click **OK**.
7. On the Processing menu, click **Start Simulation**.

## Timing Simulation

To run a timing simulation, perform the following steps:

1. On the Processing menu, click **Start Compilation** or click the **Compilation** button on the toolbar. This flattens the design and generates an internal netlist with timing delay information annotated.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
4. In the **Simulation Mode** list, select **Timing**.
5. In the **Simulation input** list, specify the vector source. You need to specify the vector file to run the simulation.
6. Click **OK**.
7. On the Processing menu, click **Start Simulation**.

## Timing Simulation Using Fast Timing Model Simulation

To run a timing simulation using a fast timing model, perform the following steps:

1. On the Processing menu, point to Start and click **Start Analysis and Synthesis**.
2. On the Processing menu, point to Start and click **Start Fitter**.

You must perform fast timing analysis before you can perform a timing simulation using the fast timing models.

3. On the Processing menu, point to Start and click **Start Classic Timing Analyzer (Fast Timing Model)**.

4. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
5. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears.
6. In the **Simulation mode** list, select **Timing using Fast Timing Model**.
7. In the **Simulation input** box, specify the vector source. You need to specify the vector file to run the simulation.
8. Click **OK**.
9. On the Processing menu, click **Start Simulation**.

## Waveform Editor

The most common input stimulus for the Quartus II Simulator are VWFs. You can use the Quartus II Waveform Editor to generate a VWF.

### Creating VWFs

To create a VWF, perform the following steps:

1. On the File menu, click **New**. The **New** dialog box appears.
2. Click the **Other Files** tab, and select **Vector Waveform File**.
3. Click **OK**. A blank Waveform Editor window appears ([Figure 1-2](#)).

**Figure 1–2. Waveform Editor Window**

4. Add nodes and buses. To add a node or bus, on the Edit menu, click **Insert** and click **Insert Node or Bus**. The **Insert Node or Bus** dialog box appears (Figure 1–3). All nodes and buses, as well as the internal signals, are listed under **Name** in the Waveform Editor window.

You can also open the **Insert Node or Bus** dialog box by double-clicking under **Name** in the Waveform Editor.

**Figure 1–3. Insert Node or Bus Dialog Box**

5. You can customize the type of node or bus you want to add. If you have a large design with many nodes or buses, you may want to use the Node Finder for node or bus selection. To use the Node Finder, click **Node Finder**. The **Node Finder** dialog box appears (Figure 1–4).

**Figure 1–4. Node Finder Dialog Box**

You can use the Node Finder to find your nodes for simulation among all the nodes and buses in your design. Use the Node Finder to filter and add nodes to your waveform. The Node Finder is equipped with multiple default filter options. By using the correct filter in the Node Finder, you can find the internal node's name and add it to your Vector Waveform File for simulation.

Your node might not appear in the simulation waveform and might be ignored during simulation. This happens because the node has been renamed or synthesized away by the Quartus II software. To prevent this from happening, Altera recommends using the register and pin nodes to simulate your design.

Table 1–1 describes twelve of the Node Finder default filters.

<b>Filter</b>	<b>Description</b>
<b>Pins: input</b>	Finds all input pin names in your design file(s).
<b>Pins: output</b>	Finds all output pin names in your design file(s).
<b>Pins: bidirectional</b>	Finds all bidirectional pin names in your design file(s).
<b>Pins: virtual</b>	Finds all virtual pin names.
<b>Pins: all</b>	Finds all pin names in your design file(s).
<b>Registers: pre-synthesis</b>	Finds all user-entered register names contained in the design after design elaboration, but before physical synthesis does any synthesis optimizations.
<b>Registers: post-fitting</b>	Finds all user-entered register names in your design file(s) that survived physical synthesis and fitting.
<b>Design Entry (all names)</b>	Finds all user-entered names in your design file(s).
<b>Post-Compilation</b>	Finds all user-entered and compiler-generated names that do not have location assignments and survived fitting.
<b>SignalTap II: pre-synthesis</b>	Finds all internal device nodes in the pre-synthesis netlist that can be analyzed by the SignalTap® II Logic Analyzer.
<b>SignalTap II: post-fitting</b>	Finds all internal device nodes in the post-fitting netlist that can be analyzed by the SignalTap II Logic Analyzer.
<b>SignalProbe</b>	Finds all SignalProbe™ device nodes in the post-fitting netlist.

To customize your own filters in the Node Finder, perform the following steps:

- a. Click **Customize**. The **Customize Filter** dialog box appears.
  - b. To configure settings, click **New**. The **New Custom Filter** dialog box appears.
  - c. In the **Filter name** box, type the name of the custom filter.
  - d. In the **Copy settings from filter** list, select the filter setting.
  - e. Click **OK**.
  - f. You can now customize your filters in the **Customize Filter** dialog box.
6. In the **Look in** box, you can view and edit the current search hierarchy path. You can type the search hierarchy path or you can browse for the hierarchy path by clicking the browse button.

You can move up the search hierarchy by selecting hierarchical names in the **Select Hierarchy Level** dialog box. This ensures that in a large design with many signals, you can specify which hierarchy you would like to get the node from to reduce the amount of signals displayed.

- After you have configured the filter and specified the correct hierarchy in the **Node Finder** dialog box, click **List** to display all relevant nodes or buses.

Select any node(s) or bus(es) from the **Nodes Found** list and click > to include it in the waveform, or you can click >> to include all nodes and buses displayed in the **Nodes Found** list.

- Click **OK**.

 You can also add nodes to the Waveform Editor by dragging nodes from the Project Navigator, Netlist Viewers, or Block Diagram, and dropping them into the Waveform Editor.

- Create a waveform for a signal. The Quartus II Waveform Editor toolbar includes some of the most common waveform settings, making waveform vector drawings easier and user friendly. [Figure 1-5](#) shows the options available on the Waveform Editor toolbar.

**Figure 1-5. Waveform Editor Toolbar**

- After you edit your waveform, save the waveform. On the File menu, click **Save As**. The **Save As** dialog box appears. Type your file name, specify the file type, and click **Save**.

Instead of using the Node Finder to insert your nodes for your VWF, you can also drag-and-drop any nodes from the Netlist Viewer to your Simulation Vector Waveform File. For more information on Netlist Viewers, refer to *Analyzing Designs with the Quartus II Netlist Viewers* in volume 1 of the *Quartus II Handbook*.

### Count Value

Count Value applies a count value to a bus to increment the value of the bus by a specified time interval. Instead of manually editing the values for each node, the Count Value feature on the Waveform Editor toolbar automatically creates the counting values for buses. This feature enables you to specify a starting value for a bus, what time interval to increment, and when to stop counting. You can also configure transition occurrences, while setting the count type and increment number. When you click on the **Count Value** button in the Waveform Editor toolbar, the **Count Value** dialog box appears (Figure 1-6). You can also open the **Count Value** dialog box by right-clicking the selected node, pointing to Value, and clicking **Count Value**.

Figure 1-6. Count Value Dialog Box

### Clock

You can use the Clock feature in the Waveform Editor toolbar to automatically generate the clock wave, rather than drawing each clock triggering pulse. To generate a clock signal with the **Clock** dialog box,

click the **Overwrite Clock** button on the Waveform Editor toolbar. Furthermore, you can determine the start and end time of a clock signal, whether to manually configure the period (the offset and the duty cycle), or whether to generate the clock based on a specified clock. [Figure 1-7](#) shows the **Clock** dialog box.

**Figure 1-7. Clock Dialog Box**

### *Arbitrary Value*

Arbitrary Value allows you to overwrite a node value over the selected waveform, waveform interval, or across one or more nodes or groups. To overwrite a node value, perform the following steps:

1. Select a node or a bus and click the **Arbitrary Value** button on the Waveform Editor toolbar ([Figure 1-5](#)). The **Arbitrary Value** dialog box appears ([Figure 1-8](#)).
2. Under **Time range**, specify the start and end time you want to overwrite for the node value.
3. In the **Radix** list, select the radix type.
4. Specify the new value you want overwritten in the **Numeric or named value** box.
5. Click **OK**.

**Figure 1–8. Arbitrary Value Dialog Box**

### Random Value

Random Value allows you to generate random node values over the selected waveform, waveform interval, or across one or more nodes or groups. [Figure 1–9](#) shows the **Random Values** dialog box.

You can generate random node values by every grid interval, every half grid interval, at random intervals, or at fixed intervals.

**Figure 1–9. Random Values Dialog Box**

## Generating a Testbench

You can export your VWF as a VHDL Test Bench File (.vht) or Verilog Test Bench File (.vt). This is useful when you want to use a vector waveform in different EDA tools. You must run an analysis and

elaboration before you can export a waveform vector. To export a waveform vector, have your vector waveform open and perform the following steps:

1. On the File menu, click **Export**. The **Export** dialog box appears.
2. In the **Save as type** list, select **VHDL Test Bench File (\*.vht)** or **Verilog Test Bench File (\*.vt)**.
3. You can optionally turn on **Add self-checking code to file**. This option adds additional logic to check the results of the output and compares it to the original VWF.

You must open your project in the Quartus II software before you can export a VWF.

For more information about using the generated test bench in other EDA tools, refer to the respective EDA simulator chapter in the *Simulation* section in volume 3 of the *Quartus II Handbook*.

## Grid Size

When you select portions of your waveform, the selection area snaps to time intervals specified in the **Grid Size** dialog box. You can customize the grid size in the Waveform Editor. You can change the grid size based on the clock settings or by setting the time period. To customize the grid size, on the Edit menu, click **Grid Size**.

## Time Bars

Add time bars in the Waveform Editor to compare edges between different signals. You can also use time bars to jump forward and backward to the next edge transition in the selected signal, and read the logic level of signals by sliding the Time Bar in your waveform. The logic level is displayed in the **Value at** column of the Waveform Editor.

The **Time Bar Organizer** dialog box enables you to create, delete, and edit a time bar, and to create a master time bar. Only one master time bar is allowed per waveform file. To use the Time Bar Organizer, on the Edit menu, point to Time Bar and click **Time Bar Organizer**.

Under **Existing time bars**, in the **Absolute time** column, the red **M** indicates the master time bar (Figure 1–10).

**Figure 1–10. Time Bar Organizer Dialog Box**

## Stretch or Compress a Waveform Interval

You can stretch or compress a waveform interval in the Waveform Editor, which enables you to analyze the effects on a waveform. For example, you can check the behavior of your design at high speeds for a short interval by using the compress option to compress the waveform. You can also use this feature to delay the transition of a signal by stretching the waveform.

You have to specify the original start and end time, and the new time for the waveform you want to stretch or compress. If you want to stretch or compress all the nodes or buses, deselect all nodes and buses and set the stretch or compress feature.

To stretch or compress a waveform interval, on the Edit menu, point to Value and click **Stretch or Compress Waveform Interval**. The **Stretch or Compress Waveform Interval** dialog box appears.

The “To time value” end time specified in the **Stretch or Compress Waveform Interval** dialog box cannot be larger than the “End Time” specified in the **Simulator Settings** page of the **Settings** dialog box (Figure 1–12). Otherwise, the Quartus II software displays a message indicating the invalid time value.

## End Time

The End Time setting enables you to change the end time of the VWF. The end time represents the maximum length of time in the VWF. You can specify the end time and your preferred time unit, and have different extension values for different nodes or buses. With the waveform open, specify the end time by performing the following steps:

1. On the Edit menu, click **End Time**. The **End Time** dialog box appears (Figure 1–11).

**Figure 1–11. End Time Dialog Box**

2. In the **Time** box, specify the end time and select the time unit in the **Time** list.
3. Under **Default extension options**, in the **Extension value** list, select the value.
4. Under **End time extension per signal**, you can select specific extension values for each signal by clicking in the **Extension value** column.

The options in the **End time** dialog box are different settings than those under **Simulation period** in the **Settings** dialog box. Simulation period is the period that the Quartus II software simulates the stimuli. End time is the maximum length of time in the VWF. For information on the simulation period, refer to [Table 1–2 on page 1–19](#).

### Arrange Group or Bus in LSB or MSB Order

You can arrange a group or bus in Least Significant Bit (LSB) or Most Significant Bit (MSB) order. If you arrange in LSB order, the LSB is on top and MSB is at bottom. If you arrange in MSB order, the MSB is on top and LSB is at bottom.

To arrange a group or bus in LSB or MSB order, perform the following steps:

1. Select the bus that you want to change the LSB or MSB order. You can also select multiple buses in the waveform editor.
2. On the Edit, point to Group and Bus Bit Order and click either **MSB on top, LSB on Bottom** to change the bus or group in MSB order or click **LSB on top, MSB on Bottom** to change the bus or group in LSB order.

## Simulator Settings

You can enhance your output, reduce debugging time, and provide better coverage before running a simulation. This section covers the different simulation modes supported by the Quartus II Simulator. Additionally, the Quartus II Simulator offers common setup features like glitch filtering, setup and hold violation detection, and simulation coverage.

To setup simulation settings, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears ([Figure 1–12](#)).

Figure 1–12. Simulator Settings Page

Table 1–2 shows the options in the **Simulator Settings** page.

<b>Table 1–2. Quartus II Simulator Settings (Part 1 of 2)</b>	
<b>Settings and Options</b>	<b>Description</b>
<b>Simulation mode (1)</b>	<p><b>Functional</b> This simulation mode uses a pre-synthesis compiler database to simulate the logical performance of a project without the timing information. This mode enables you to check the functionality of the design. All nodes and buses are preserved in this simulation because functional simulation is performed before synthesis, partitioning, or fitting. A VWF is required to perform this simulation mode.</p> <p><b>Timing</b> This simulation mode takes the compiled netlist that includes timing information. With this simulation mode, you can check setup, hold violation, glitches, and simulation coverage. You can remove nodes or buses using the Quartus II Compiler when logic is optimized. This simulation mode uses the worst case timing model.</p> <p><b>Timing using Fast Timing Model</b> This simulation mode is similar to timing simulation but this mode uses the best-case timing model.</p>
<b>Simulation input</b>	<p>You must include the vector file in the <b>Simulation input</b> box. You can type the name of the file or use the browse button to open the <b>Select File</b> dialog box. In the <b>Files of type</b> list, you can select Vector Waveform File (*.vwf), Compressed Vector Waveform File (*.cvwf), Value Change Dump File (*.vcd), Vector Table Output File (*.tbl), Vector Text File (*.vec), Simulation Channel File (.scf), or <b>All Files (*.*)</b>.</p> <p>TBL files contain input vectors and output logic levels in tabular-format list. You can generate this file using a VWF. However, if you would like to maintain, view, or update the vectors, VWFs offer better visibility. VWF or TBL file formats are interchangeable. You can generate TBL files from VWFs and vice versa. You can create a VWF with the Waveform Editor. For more information on the Waveform Editor, refer to <a href="#">“Waveform Editor” on page 1–5</a>.</p> <p>The Quartus II software also supports MAX+PLUS® II simulation vector files, such as VEC and SCF.</p> <p>A CVWF is the simplified version, non-readable, format of the VWF format. This file type is in binary format and is generally smaller in file size. You can use CVWFs in the Waveform Editor and simulation.</p> <p>A VCD file is an ASCII file which contains header information, variable definitions, and the value changes for specified variables, or all variables, in a given design. The value changes for a variable are given in scalar or vector format, based on the nature of the variable.</p>

**Table 1–2. Quartus II Simulator Settings (Part 2 of 2)**

Settings and Options	Description
<b>Simulation period</b>	<p>The simulation period determines the length of time that the simulator runs the stimuli with the maximum period being equal to the end time of a VWF. If the simulation period is configured shorter than the end time, all signals beyond the simulation period are displayed as Unknown (X). Therefore, you can also shorten the simulation period or end the simulation earlier by selecting <b>End Simulation at</b> and specifying the time and selecting the time unit. If the simulation period is configured longer than the end time, the simulation will stop at the end time. For information on the end time, refer to “<a href="#">End Time</a>” on page 1–16.</p>
<b>Glitch filtering options</b>	<p>Specifies whether to enable glitch filtering for simulations. You can select one of the following options:</p> <p><b>Auto</b>—The Simulator performs glitch filtering when SAF generation is enabled in the <b>Simulation Output Files</b> page of the <b>Settings</b> dialog box.</p> <p><b>Always</b>—The Simulator always performs glitch filtering, even if SAF generation is not enabled.</p> <p><b>Never</b>—The Simulator never performs glitch filtering, even if SAF generation is enabled.</p>
<b>More Settings</b>	<p>If you click <b>More Settings</b>, the <b>More Simulator Settings</b> dialog box appears. The following options are available under <b>Existing option settings</b>.</p> <p><b>Cell Delay Model Type</b> Specifies the type of delay model to be used for cell delays: transport or inertial. The default is transport.</p> <p><b>Interconnect Delay Model Type</b> Specifies the type of delay model to be used for interconnect delays: transport or inertial. The default is transport.</p> <p><b>Preserve fewer signal transition to reduce memory requirements</b> This option is effective on lower performance workstations because turning on this option flushes signal transitions from memory to disk for memory optimization.</p>

**Note to Table 1–2:**

- (1) The Quartus II Simulator may flag an error message if zero-time oscillation happens in your design. Zero-time oscillation happens when a particular output signal does not achieve a stable output value at a particular fixed time, which may be due to your design containing combinational logic path loops.

## Simulation Verification Options

Figure 1–13 shows the simulation verification page.

**Figure 1–13. Simulation Verification Page**

Table 1–3 shows the options in the simulation verification page.

<b>Table 1–3. Quartus II Simulation Verification (Part 1 of 2)</b>	
<b>Settings and Options</b>	<b>Description</b>
<b>Check outputs</b>	<p><b>Check outputs</b> checks expected outputs against actual outputs in the simulation report. After turning on <b>Check outputs</b>, click the <b>Waveform Comparison Settings</b> button. The <b>Waveform Comparison Settings</b> dialog box appears.</p> <p>In the <b>Waveform Comparison Settings</b> dialog box, you can specify the waveform comparison time frame and the comparison options. You can also set the tolerance level for all the signals by specifying the tolerance limit in the <b>Default comparison timing tolerance</b> box. The <b>Maximum comparison mismatches</b> box is the amount of mismatches the Quartus II Simulator is allowed to accept before it stops comparing.</p> <p>You can also set the type of transition the comparison should trigger in the <b>Waveform Comparison Settings</b> dialog box. You can assign trigger comparisons based on <b>Input signal transition edges</b>, <b>All signal transition edges</b>, or <b>Selected Signal transition edges</b>.</p> <p>To customize the waveform comparison matching rules, you can also click the <b>Comparison Rules</b> button. The <b>Comparison Rules</b> dialog box appears, allowing you to customize the comparison matching rules.</p>
<b>Setup and hold time violation detection</b>	<p>This option detects setup and hold time violation. Setup time is the period required by a synchronous signal to stabilize before the arrival of a clock edge. Hold time is the time required by a synchronous signal to maintain after the same clock edge. If the <b>Setup and hold time violation detection</b> option is turned on, a warning in the Messages windows appears if any setup or hold time violation is detected during the simulation. This option is only for Timing and Timing using Fast Timing Model simulation modes.</p>
<b>Glitch detection</b>	<p>Conditions happen when two or more signals toggle simultaneously and can cause glitches or unwanted short pulses. The <b>Glitch detection</b> option enables you to detect glitches and specify the time interval that defines a glitch. If two logic level transitions occur in a period shorter than the specified time period, the resulting glitch is detected and reported in the <b>Processing</b> tab of the Messages window.</p> <p>If you turn on the <b>Glitch detection</b> option, you can specify the acceptable glitch width. A Messages window appears when a pulse is smaller than the specified glitch width that is detected. The <b>Glitch detection</b> option is only available for Timing and Timing using Fast Timing Model simulation modes.</p>

**Table 1–3. Quartus II Simulation Verification (Part 2 of 2)**

<b>Settings and Options</b>	<b>Description</b>
<b>Simulation coverage reporting</b>	This option reports the ratio of outputs (coverage) actually simulated to the number of outputs in the netlist and is expressed as a percentage. When you turn on the <b>Simulation coverage reporting</b> option, the <b>Report Settings</b> button is available. If you click <b>Report Settings</b> , the <b>Report Settings</b> dialog box appears. The three types of coverage reports you can select from are <b>Display complete 1/0 value coverage report</b> , <b>Display missing 1-value coverage report</b> , and <b>Display missing 0-value coverage report</b> .
<b>Disable setup and hold time violation detection for input registers of bi-directional pins</b>	This option enables you to disable setup and hold time violations detection in input registers of all bidirectional pins in the simulated design during Timing or Timing using Fast Timing Model simulation.

## Simulation Output Files Options

Figure 1-14 shows the simulation output file page.

**Figure 1-14. Simulation Output Files Page**

Table 1–4 shows the options in the simulation output file page.

<b>Table 1–4. Quartus II Simulation Output Files</b>	
<b>Setting and Options</b>	<b>Description</b>
<b>Simulation output waveform</b>	<p>Specify the simulation output waveform options.</p> <p><b>Automatically add pins to simulation output waveforms</b> The <b>Automatically add pins to simulation output waveforms</b> option automatically adds all outputs that are available in the design to the waveform reports. If your design has large amounts of outputs, turning on this option ensures all outputs are monitored during simulation.</p> <p><b>Overwrite simulation input file with simulation results</b> This option overwrites the vector source file with simulation results. This option is ignored when the <b>Check outputs</b> setting is turned on. This option adds the result to the vector file and generally, it can give you more visibility during the debugging process. (1)</p> <p><b>Group bus channel in simulation results</b> This option automatically groups bus channels in the output waveform that are shown in the simulation reports. By turning off this option, all output waveforms have a node to represent each bus signal.</p>
<b>Signal activity output for power analysis</b>	When you perform your simulation with the Quartus II Simulator, you can generate a SAF which is used by the PowerPlay Power Analyzer to assist you with power analysis. (2), (3)
<b>VCD output for power analysis</b>	When you perform simulation with the Quartus II Simulator, you can generate a VCD file, which is used by the PowerPlay Power Analyzer to assist you with power analysis. (2), (3)

**Notes to Table 1–4:**

- (1) A backup copy of the source vector file is saved under the **db** folder with the name `<project>.sim_ori.<vector file format type>`.
- (2) Instead of using the SAF or Generate VCD file (\*.vcd), you can also save your output waveform as a VCD file to perform power analysis.
- (3) For more information about the PowerPlay Power Analyzer, refer to the *PowerPlay Power Analysis* chapter in volume 3 of the *Quartus II Handbook*.

## Simulation Report

Comprehensive reports are shown after the completion of each simulation. These reports are important to ensure designs meet timing and logical correctness. These simulation reports also play an important role in debugging.

### Simulation Waveform

Simulation Waveforms are part of the Simulation report. In this report, the stimuli and the results of the simulation are displayed.

You can export the simulation waveform as a VHDL Test Bench File or a Verilog Test Bench File for use in other EDA tools. You can also save a simulation as a VWF or Vector Table Output File for use with the Quartus II software.

When you try to edit the Simulation Waveform, the **Edit Input Vector File** dialog box appears, asking whether you would like to edit the vector input file with the results of the simulation or if you would like to overwrite the vector input file with other vector inputs ([Figure 1-15](#)).

**Figure 1-15. Edit Input Vector File**

You can overwrite your simulation input file with the simulation results so that your input vector file is updated with the resulting waveform after a simulation. For more information, refer to the **Overwrite simulation input file with simulation results** option in [Table 1-2](#).

If you do not want to overwrite the simulation input file in every simulation run, perform the following to overwrite simulation input files with simulation results after a simulation:

On the Processing Menu, point to Simulation Debug and click **Overwrite Vector Inputs with Simulation Outputs**.

## Simulating Bidirectional Pin

A bidirectional pin is represented in the waveform by two channels. One channel represents the input to the bidirectional pin, and the other channel represents the output from the bidirectional pin. You can enter the input channel into the waveform by using the **Node Finder** dialog box. The output channel is automatically created by the Quartus II Simulator and named `<bidir pin name> ~result`.

## Logical Memories Report

The Quartus II software writes out the contents of each memory module after simulation. Therefore, if you use memory cells in your design, you can analyze the contents of the logic memory structures in the device in the Logical Memories Report. The Logical Memories Report displays individual reports for each memory block and contains the data stored in the memory cell used at the end of simulation.

After being simulated, a memory module's contents are stored in the Logical Memories section of the simulation report file.

To view this section, perform the following steps:

1. On the Processing menu, click **Simulation Report**. The Simulation Report window appears.
2. In the report window, click on the "+" next to **Logical Memories**.

## Simulation Coverage Reports

The **Coverage Summary** report contains the following summary information for the simulation:

- Total toggling coverage as a percentage
- Total nodes checked in the design
- Total output ports checked
- Total output ports with complete 1/0-value coverage
- Total output ports with no 1/0-value coverage
- Total output ports with no 1-value coverage
- Total output ports with no 0-value coverage

The **Complete 1/0-Value Coverage** report lists the following information:

- Node name
- Output port name
- Output port type for output ports that toggle between 1 and 0 during the simulation

The **Missing 0-Value Coverage** report and **Missing 1-Value Coverage** report list the following information:

- Node name
- Output port name
- Output port type for output ports that do not toggle to the designated value

For more information about Simulation Coverage reports, refer to the **Simulation coverage reporting** option in [Table 1-2 on page 1-19](#).

The following are individual reports and their definition:

**Complete 1/0 value coverage report**

Displays all the nodes or buses that toggle between 1 and 0 during simulation.

**Missing 1-value coverage and Missing 0-value coverage reports**

Displays all the nodes that do not toggle to the designated value.

**Comparing Two Waveforms**

You can compare your simulation results against previous simulations using the compare option. To compare two waveforms in the **Simulation Report**, turn on the **Check outputs** option. For more information on the **Check outputs** option, refer to [Table 1-2 on page 1-19](#). With the **Check outputs** option turned on, the two comparable waveforms are visible in black and red. The black waveforms represent the original output or the expected output, and the red waveforms represent the compared output or the actual output. [Figure 1-16](#) shows an example of expected output waveform versus actual output waveform.

**Figure 1-16. Example of Simulation Waveform from the Simulation Report When Check Output is Turned On**

## Debugging with the Quartus II Simulator

The Quartus II software includes tools to help with simulation debugging. This section covers some debugging tools and their use.

### Breakpoints

Inserting breakpoints into the simulation process enables the simulator to break at the desired time or on the desired node or bus condition. You can monitor the activity of nodes or buses during specified times and pinpoint the cause of mismatched signal levels between expected and actual. To use breakpoints, perform the following steps:

1. On the Processing menu, point to Simulation Debug and click **Breakpoints**. The **Breakpoints** dialog box appears (Figure 1–17).

Figure 1–17. Breakpoints Dialog Box

2. Click **New** to create a new breakpoint. The **New Breakpoint** dialog box appears. In this dialog box, you can specify the name, the equation, and the action of the breakpoint. You can also enable or disable this breakpoint by using the **Enable Breakpoint** check box.
3. In the Equation text box, click **condition**. You can configure the logical conditions of individual nodes or buses, or you can set the time.
4. After you configure the equation conditions, select the action for the Quartus II Simulator. In the Action drop down list, select **Stop**, **Warning Message**, **Error Message**, or **Information Message**. This selection defines the action once the condition is met.

5. You can also enter the text that appears when the Simulator encounters the breakpoint. If you do not make an entry in this box, the Quartus II software displays a default message.

## Updating Memory Content

If your design includes memories, when the simulator stops at a breakpoint, you can view and edit the contents of the memories. To view your memories during a breakpoint in the simulation, on the Processing menu, point to Simulation Debug and click **Embedded Memory**.

## Last Simulation Vector Outputs

The Last Simulation Vector Outputs command opens the Output Simulation Waveforms report generated by the last simulation. To use this command, on the Processing menu, point to Simulation Debug and click **Last Simulation Vector Outputs**.

You can open the current input vectors that you defined in the **Simulator Settings** dialog box with the Current Vector Inputs command. To use this command, on the Processing menu, point to Simulation Debug and click **Current Vector Inputs**. Lastly, you can overwrite the vector source file with the simulation outputs which open the resulting file.

## Conventional Debugging Process

During the design phase, tapping out internal signals is a common practice to debug simulation errors. Therefore, the Quartus II software enables you to tap out the signal for simulation debug and also enables you to pull out the internal signal to the physical I/O. The Quartus II software also offers SignalTap II and SignalProbe to further assist you with debugging.

### *Accessing Internal Signals for Simulation*

You can conventionally debug by probing out the internal signals, which enables you to preserve the internal signals during synthesis. You can probe the internal signal by selecting the node or bus and specifying a name, and then adding an output port to the schematic with a similar name. [Figure 1-18](#) shows an example of accessing internal signals for simulation from a schematic diagram.

**Figure 1–18. Example of Tapping Out Internal Signal**

For timing simulations, the simulation netlist is based on the Compilation post-Synthesis and post-Fitting netlist. Therefore, some of the internal nodes or buses are optimized away during compilation of the netlist. If an internal node is optimized away, the Quartus II software shows a warning in the **Warning** tab of the Messages window similar to the following message:

Warning: Compiler packed, optimized or synthesized away node "DataU". Ignored vector source file node.

This internal node is ignored by the Quartus II Simulator.

If you would like to tap out the D and Q ports of registers, turn on **Add D and Q ports of register node to Simulation Output Waveform** from the Assignment Editor. This feature is only available for functional simulations.

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ←
```

The Scripting Reference Manual includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

You can change the Functional, Timing, or Timing using Fast Timing Model simulation modes with the following command:

```
simulation_mode <mode> ←
```

To initialize the simulation for the current design, use the following command. During initialization, the Simulator builds the simulation netlist and sets the simulation time to zero.

The option `-ignore_vector_file` is set to **Off** by default, when the source vector file exists for simulation. The Quartus II software ignores the source vector file during simulation if the option `-ignore_vector_file` is set to **On**. The `-end_time` option is used only when the `-ignore_vector_file` option is set to **On**.

```
initialize_simulation [-h | -help] [-long_help] [-check_outputs <On | Off>] \
[-end_time <end_time>] [-glitch_filtering <On | Off>] [-ignore_vector_file <On | Off>] \
[-memory_limiter <On | Off>] [-power_vcd_output <target_file>] [-read_settings_files <On | Off>] \
[-saf_output <target_file>] [-sim_mode <functional | timing | timing_using_fast_timing_model >] \
[-vector_source <vector_source_file>] [-write_settings_files <On | Off>] \
-simulation_results_format <VWF | CVWF | VCD> -vector_source <vector source file>
```

To force the specified signal or group of signals to the specified value, type the following at a command prompt:

```
force_simulation_value [-h | -help] [-long_help] -node <hpath> <value> ←
```

To turn on the simulator to simulate the design for a specified time, type the following at a command prompt:

```
run_simulation [-h | -help] [-long_help] [-time <time>] ←
```

If you do not specify the length of time the simulation runs, it runs until the simulation is complete.

To create a breakpoint with a specified equation and action, type the following at a command prompt:

```
create_simulation_breakpoint [-h | -help] [-long_help] \  
-action [Give Warning | Give Info | Give Error] \  
-breakpoint <breakpoint_name> -equation <equation> [-user_message <message_text>] ←
```

To delete a breakpoint with a specified name, type the following at a command prompt:

```
delete_simulation_breakpoint [-h | -help] [-long_help] \  
-breakpoint <breakpoint_name> ←
```

## Conclusion

Simulation plays an important role in ensuring the quality of a product. The Quartus II software offers various tools to assist you with simulation and helps reduce debugging time with the introduction of features like Glitch Filtering and Breakpoints.

# Document Revision History

Table 1-5 shows the revision history for this chapter.

<i>Table 1-5. Document Revision History</i>		
<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized "Referenced Documents" on page 1-33.	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>● Updated a command in Scripting Support.</li> <li>● Updated Breakpoints.</li> <li>● Added procedure to Logical Memories Report.</li> <li>● Updated sections, added sections and deleted sections in Simulator Settings.</li> <li>● Updated Simulation Report.</li> <li>● Updated Table 1-2.</li> <li>● Added Arrange Group or Bus in LSB or MSB Order.</li> <li>● Updated Creating VWFs.</li> <li>● Added Referenced Documents.</li> </ul>	Updated for the Quartus II software version 7.1.
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only. No other changes made to chapter.	—
November 2006 v6.1.0	Updated for the Quartus II software version 6.1. <ul style="list-style-type: none"> <li>● Added references to Value Change Dump File (.vcd)</li> <li>● Added Random Value section</li> <li>● Other minor changes</li> </ul>	Updated for the Quartus II software version 6.1.
May 2006 v6.0.0	Initial release.	—

### Introduction

An Altera® software subscription includes a license for the ModelSim-Altera software on a PC or UNIX platform. The ModelSim-Altera software can be used to perform functional register transfer level (RTL), post-synthesis, and gate-level timing simulations for either Verilog HDL or VHDL designs that target an Altera FPGA. This chapter provides detailed instructions on how to simulate your design in the ModelSim-Altera version or the Mentor Graphics® ModelSim® software version. This chapter gives you details on the specific libraries that are needed for a functional RTL simulation or a gate-level timing simulation.

This document describes using ModelSim-Altera software version 6.1g and the Mentor Graphics ModelSim software version 6.1g. It also contains references to features available in the Altera Quartus® II software version 7.2.

The following topics are discussed in this chapter:

- “Background”
- “Software Compatibility” on page 2-3
- “Altera Design Flow with ModelSim or ModelSim-Altera Software” on page 2-3
- “Functional RTL Simulation” on page 2-5
- “Post-Synthesis Simulation” on page 2-16
- “Gate-Level Timing Simulation” on page 2-23
- “Simulating Designs that Include Transceivers” on page 2-37
- “Using the NativeLink Feature with ModelSim” on page 2-44
- “Scripting Support” on page 2-50
- “Software Licensing and Licensing Setup” on page 2-51

For more information about the current Quartus II software version, refer to the Altera website at [www.altera.com](http://www.altera.com).

### Background

The ModelSim-Altera software version 6.1g is included with your Altera software subscription and can be licensed for the PC, Solaris, or Linux platforms to support either Verilog HDL or VHDL hardware description language (HDL) simulation. The ModelSim-Altera software supports VHDL or Verilog functional RTL, post-synthesis, and gate-level timing simulations for all Altera devices.

Table 2–1 describes the differences between the Mentor Graphics ModelSim SE/PE and ModelSim-Altera software versions.

<b>Table 2–1. Comparison of ModelSim Software Versions</b>				
<b>Product Feature</b>	<b>ModelSim SE</b>	<b>ModelSim PE</b>	<b>ModelSim-Altera</b>	<b>ModelSim-Altera Web Edition</b>
100% VHDL, Verilog, mixed-HDL support	Optional	Optional	Supports only single-HDL simulation	Supports only single-HDL simulation
Complete HDL debugging environment	✓	✓	✓	✓
Optimized direct compile architecture	✓	✓	✓	✓
Industry-standard scripting	✓	✓	✓	✓
Flexible licensing	✓	Optional	✓	—
Verilog PLI support. Interfaces Verilog HDL designs to customer C code and third-party software	✓	✓	✓	✓
VHDL FLI support. Interfaces VHDL designs to customer C code and third-party software	✓	—	—	—
Standard Delay Format File annotation	✓	✓	✓ <sup>(1)</sup>	✓ <sup>(1)</sup>
Advanced debugging features and language-neutral licensing	✓	—	—	—
Customizable, user-expandable graphical user interface GUI and integrated simulation performance analyzer	✓	—	—	—
Integrated code coverage analysis and SWIFT support	✓	—	—	—
Accelerated VITAL and Verilog HDL primitives (3 times faster), and register transfer level (RTL) acceleration (5 times faster)	✓	—	—	—
Platform support	PC, UNIX, Linux	PC only	PC, UNIX, Linux	PC only
Precompiled Libraries	No	No	Yes	Yes

**Note to Table 2–1:**

(1) ModelSim-Altera will only allow SDF annotation to modules in the Altera library.

## Software Compatibility

Table 2-2 shows which ModelSim-Altera software version is compatible with the Quartus II software versions. ModelSim versions provided directly from Mentor Graphics do not correspond to specific Quartus II software versions.

For help with ModelSim-Altera licensing set up, refer to “[Software Licensing and Licensing Setup](#)” on page 2-51.

**Table 2-2. Compatibility Between Software Versions**

ModelSim-Altera Software	Quartus II Software (1)
ModelSim-Altera software version 6.1g	Quartus II software version 6.1, 7.0, 7.1, and 7.2
ModelSim-Altera software version 6.1d	Quartus II software version 6.0
ModelSim-Altera software version 6.0e	Quartus II software version 5.1
ModelSim-Altera software version 6.0c	Quartus II software version 5.0
ModelSim-Altera software version 5.8.e ModelSim-Altera software version 5.8	Quartus II software version 4.2

*Note to Table 2-2:*

- (1) Updated ModelSim-Altera precompiled libraries are available for download on Altera’s website for each release of the Quartus II service pack.

## Altera Design Flow with ModelSim or ModelSim-Altera Software

This chapter contains the following sections:

- Functional RTL simulations
- Post-synthesis simulations
- Gate-level timing simulations
- Using the NativeLink® feature with ModelSim

Figure 2-1 illustrates an Altera design flow using the Mentor Graphics ModelSim software or ModelSim-Altera software.

**Figure 2-1. Altera Design Flow with ModelSim-Altera and Quartus II Software**

**Note to Figure 2-1:**

- (1) If you are performing a functional simulation through NativeLink, you must complete analysis and elaboration first.

## Functional RTL Simulation

A functional RTL simulation is performed before a gate-level simulation or post-synthesis simulation. Functional RTL simulation verifies the functionality of the design before synthesis and place-and-route. This section provides detailed instructions on how to perform a functional RTL simulation in the ModelSim-Altera software and highlights some of the differences in performing similar steps in the Mentor Graphics ModelSim software versions for Verilog HDL and VHDL designs.

### Functional Simulation Libraries

Pre-compiled libraries are available for functional simulation with the ModelSim-Altera software. These libraries include the **lpm** library and the **altera\_mf** library. To create these libraries for simulation with the ModelSim SE/PE software, compile the library files described in the following sections.

#### *lpm Simulation Models*

To simulate designs containing lpm functions, use the following functional simulation models:

- **220model.v** (for Verilog HDL)
- **220pack.vhd** and **220model.vhd** (for VHDL)

When you are simulating a design that uses VHDL-1987, use the **220model\_87.vhd** model file.

Table 2-3 shows the location of these simulation model files and precompiled libraries in the Quartus II software and the ModelSim-Altera software.

**Table 2-3. Location of lpm Simulation Models Files and Pre-Compiled Libraries**

Software	Location
Quartus II	<Quartus II installation directory>\eda\sim_lib\ (1)
ModelSim-Altera	<ModelSim-Altera installation directory>\altera\<HDL>\220model\ (2), (3)

**Notes to Table 2-3:**

- (1) For ModelSim SE/PE, compile the files provided with the Quartus II software.
- (2) For ModelSim-Altera, use the precompiled libraries for simulation.
- (3) <HDL> can be either Verilog HDL or VHDL.

For more information about LPM functions, refer to the Quartus II Help.

### Altera Megafunction Simulation Models

To simulate a design that contains Altera megafunctions, use the following simulation models:

- `altera_mf.v` (for Verilog HDL)
- `altera_mf.vhd` and `altera_mf_components.vhd` (for VHDL)

 When you are simulating a design that uses VHDL-1987, use `altera_mf_87.vhd`.

Table 2-4 shows the location of these simulation files and precompiled libraries in the Quartus II software and the ModelSim-Altera software.

Software	Location
Quartus II	<Quartus II installation directory>\eda\sim_lib\ (1)
ModelSim-Altera	<ModelSim-Altera installation directory>\altera\<HDL>\altera_mf (2), (3)

**Notes to Table 2-4:**

- (1) For ModelSim SE/PE, compile the files provided with the Quartus II software.
- (2) For ModelSim-Altera, use the precompiled libraries for simulation.
- (3) <HDL> can be either Verilog HDL or VHDL.

The following Altera megafunctions require device atom libraries to perform a functional simulation in a third-party simulator:

- `altclkbuf`
- `altclkctrl`
- `altdqs`
- `altdq`
- `altddio_in`
- `altddio_out`
- `altddio_bidir`
- `altufm_none`
- `altufm_parallel`
- `altufm_spi`
- `altmemmult`
- `altremote_update`

The device atom library files are located in the following directory:

<Quartus II installation directory>/eda/sim\_lib

### Low-Level Primitive Simulation Models

You can simulate a design that contains low-level Altera primitives with the following simulation models:

- `altera_primitives.v` (for Verilog HDL)
- `altera_primitives.vhd` and `altera_primitives_components.vhd` (for VHDL)

Table 2-5 shows the location of these simulation library files and precompiled libraries in the Quartus II software and the ModelSim-Altera software.

Software	Location
Quartus II	<Quartus II installation directory>\eda\sim_lib (1)
ModelSim-Altera	<ModelSim-Altera installation directory>\altera\<HDL>\altera (2), (3)

#### Notes to Table 2-5:

- (1) For ModelSim SE/PE, compile the files provided with the Quartus II software.
- (2) For ModelSim-Altera, use the precompiled libraries for simulation.
- (3) <HDL> can be either Verilog HDL or VHDL.

## Simulating VHDL Designs

Use the following instructions to perform a functional RTL simulation for VHDL designs in the ModelSim software.

The steps in the following section assume you have already created a ModelSim project.

The ModelSim-Altera software comes with precompiled simulation libraries. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to “[Compile Testbench and Design Files into Work Library](#)” on page 2-9.

### Create Simulation Libraries

Simulation libraries are required to simulate a design that contains an Altera primitive, lpm function, or Altera megafunction. These libraries have already been compiled if you are using the ModelSim-Altera software. However, if you are using the Mentor Graphics ModelSim software, you must create the simulation libraries and link them to your design correctly.

### Create Simulation Libraries Using the ModelSim GUI

Perform the following steps to create simulation libraries:

1. In the ModelSim software, on the File menu, point to New and click **Library**. The **Create a New Library** dialog box appears.
2. Select **a new library and a logical mapping to it**.
3. In the **Library Name** box, type the name of the newly created library.

For example, the library name for Altera megafunctions should be **altera\_mf**, and the library name for LPM should be **lpm**.

4. Click **OK**.

### Create Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vlib altera_mf ←  
vmap altera_mf altera_mf ←  
vlib lpm ←  
vmap lpm lpm ←  
vlib altera ←  
vmap altera altera ←
```

### *Compile Simulation Models into Simulation Libraries*

The following steps are not required for the ModelSim-Altera software.

### Compile Simulation Models into Simulation Libraries Using the ModelSim GUI

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, point to Add to Project and click **Existing File**.
2. Browse to the *<Quartus II installation directory>/eda/sim\_lib* and add the necessary simulation model files to your project.

The **altera\_mf.vhd** model file should be compiled into the **altera\_mf** library. The **220pack.vhd** and **220model.vhd** model files should be compiled into the **lpm** library.

3. In the Workspace window, select the simulation model file, and on the View menu, click **Properties**.

4. Choose the correct library from the **Compile to Library** list.
5. Click **OK**.
6. On the **Compile** menu, click **Compile selected**.

### Compile Simulation Models into Simulation Libraries at the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vcom -work altera_mf <Quartus II installation directory>/eda/sim_lib/altera_mf_components.vhd ↵
vcom -work altera_mf <Quartus II installation directory>/eda/sim_lib/altera_mf.vhd ↵
vcom -work lpm <Quartus II installation directory>/eda/sim_lib/220pack.vhd ↵
vcom -work lpm <Quartus II installation directory>/eda/sim_lib/220model.vhd ↵
vcom -work altera <Quartus II installation directory>/eda/sim_lib/altera_primitives_components.vhd ↵
vcom -work altera <Quartus II installation directory>/eda/sim_lib/altera_primitives.vhd ↵
```

### Compile Testbench and Design Files into Work Library

Compile a testbench and design files into a work library by clicking **Compile All** or by clicking the **Compile All** toolbar icon on the **Compile** menu.

### Compile Testbench and Design Files into Work Library Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vcom -work work <my_test_bench.vhd> <my_design_files.vhd>↵
```

Resolve compile-time errors before proceeding to the following section.

### Loading the Design

To load a design, perform the following steps:

1. On the **Simulate** menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Expand the work library in the **Start Simulation** dialog box.
3. Select the top-level design unit (your testbench).
4. In the **Resolution** list, select **ps**.
5. Click **OK**.

### Loading the Design Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vsim work.<my_test bench> -t ps ↵
```

### Running the Simulation

Perform the following steps to run a simulation:

1. On the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ↵
```

### Running the Simulation Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ↵  
run <time period> ↵
```

## Simulating Verilog HDL Designs

The following instructions provide step-by-step instructions to perform functional RTL simulation for Verilog HDL designs in the ModelSim software.

The following steps assume you have already created a ModelSim project.

If you are using the ModelSim-Altera software, a set of precompiled libraries are created when you install the software. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to [“Compile Testbench and Design Files into Work Library” on page 2–12](#).

### Create Simulation Libraries

Simulation libraries are needed to properly simulate a design that contains an lpm function or an Altera megafunction. These libraries have already been compiled if you are using the ModelSim-Altera software.

However, if you are using the Mentor Graphics ModelSim software, you must create the simulation libraries and correctly link them to your design.

### Create Simulation Libraries Using the ModelSim GUI

Perform the following steps to create simulation libraries:

1. On the File menu, point to New and click **Library**. The **Create a New Library** dialog box appears.
2. Select **a new library and a logical mapping to it**.
3. In the **Library Name** box, type the name of the newly created library.

For example, the library name for Altera megafunctions should be **altera\_mf**, and the library name for LPM should be **lpm**.

4. Click **OK**.

### Create Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vlib altera_mf ←  
vmap altera_mf altera_mf ←  
vlib lpm ←  
vmap lpm lpm ←  
vlib altera ←  
vmap altera altera ←
```

### *Compile Simulation Models into Simulation Libraries*

The following steps are not required for the ModelSim-Altera software.

### Compile Simulation Models into Simulation Libraries Using the ModelSim GUI

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, point to Add to Project and click **Existing File**.
2. Browse to the *<Quartus II installation directory>/eda/sim\_lib* and add the necessary simulation model files to your project.

Compile the **altera\_mf.v** into the **altera\_mf** library. Compile the **220model.v** into the **lpm** library.

3. Select the simulation model file and on the View menu, click **Properties**.
4. Choose the correct library from the **Compile to Library** list.
5. Click **OK**.
6. On the Compile menu, click **Compile selected**.

### Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vlog -work altera_mf <Quartus II installation directory>/eda/sim_lib/altera_mf.v ↵
vlog -work lpm <Quartus II installation directory>/eda/sim_lib/220model.v ↵
vlog -work altera <Quartus II installation directory>/eda/sim_lib/altera_primitives.v ↵
```

### *Compile Testbench and Design Files into Work Library*

Compile a testbench and design files into a work library on the Compile menu by clicking **Compile All** or clicking the **Compile All** toolbar icon on the Compile menu.

### Compile Testbench and Design Files into Work Library Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vlog -work work <my_test_bench.v> <my_design_files.v>↵
```

Resolve compile-time errors before proceeding to the following section.

### *Loading the Design*

Perform the following steps to load a design:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Libraries** tab.
3. In the **Search Libraries** box, click **Add**.
4. Specify the location of the **lpm** or **altera\_mf** simulation libraries.

If you are using the ModelSim-Altera version, refer to [Table 2-3 on page 2-5](#) and [Table 2-4 on page 2-6](#) for the location of the precompiled simulation libraries. If you are using the Mentor Graphics ModelSim software version, browse to the library that was created earlier.

5. In the **Load Design** dialog box, click the **Design** tab and expand the work library.
6. Select the top-level design unit (your testbench).
7. In the **Resolution** list, select **ps**.
8. Click **OK**.

#### Loading a Design Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vsim -L altera_mf -L lmp work.<my_test_bench> -t ps ↵
```

#### Running the Simulation

Perform the following steps to run a simulation:

1. On the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag the signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ↵
```

#### Running the Simulation Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ↵
run <time period> ↵
```

#### Verilog HDL Functional RTL Simulation with Altera Memory Blocks

Both ModelSim software products support simulating Altera memory megafunctions initialized with Hexadecimal (Intel-Format) File (**.hex**) or RAM initialization files (**.rif**).

Although synthesis is able to read a Memory Initialization File (.mif), this memory file is not supported with third-party tools and must be converted to either a Hexadecimal (Intel-Format) File or RAM Initialization File.

Table 2–6 summarizes the different types of memory initialization file formats that are supported with each RTL language.

<b>Table 2–6. Simulation Support for Memory Initialization Files</b>		
<b>File</b>	<b>Verilog HDL</b>	<b>VHDL</b>
Hexadecimal (Intel-Format) File	Yes (1)	Yes
Memory Initialization File	No	No
RAM Initialization File	Yes (2)	No

**Notes to Table 2–6:**

- (1) For memories and library files from the Quartus II software version 5.0 and earlier, you must use a PLI library containing the `convert_hex2ver` function.
- (2) Requires the `USE_RIF` macro to be defined, described later in this section.

To simulate your design by converting your Memory Initialization File into either a Hexadecimal (Intel-Format) File or a RAM Initialization File, perform the following steps:

1. Convert a Memory Initialization File to a Hexadecimal (Intel-Format) File or RAM Initialization File in the Quartus II software.

**Converting a Memory Initialization File to a Hexadecimal (Intel-Format) File**

- a. Open the Memory Initialization File. On the File menu, click **Save As**. The **Save As** dialog box appears.
- b. In the **Save as type** list, select **Hexadecimal (Intel-Format) File (\*.hex)**.
- c. Click **OK**.

**Convert a Memory Initialization File to a RAM Initialization File**

- a. Open the Memory Initialization File and on the File menu, click **Export**. The **Export** dialog box appears.
- b. In the **Save as type** list, select **RAM Initialization File (\*.rif)**.

- c. Click **OK**.

Alternatively, you can convert a Memory Initialization File to a RAM Initialization File using the **mif2rif.exe** utility located in the `<Quartus II installation>/bin` directory.

```
mif2rif <mif_file> <rif_file> ↵
```

2. Modify the HDL file generated by the MegaWizard® Plug-In Manager.

The Altera memory custom megafunction variation file includes the `lpm_file` parameter for LPM memories such as `LPM_ROM`, or the `init_file` for Altera specific memories such as an `altsyncram`, to point to the initialization file.

In a text editor, open the custom megafunction variation file and edit the `lpm_file` or `init_file` to point to the Hexadecimal (Intel-Format) File or RAM Initialization File, as shown in the following example:

```
lpm_ram_dp_component.lpm_file = "<path to HEX/RIF>"
```

3. Compile the functional library files with compiler directives.

If you use a Hexadecimal (Intel-Format) File, no compiler directives are required. If you use a RAM Initialization File, you must define the **USE\_RIF** macro when compiling the model library files. For example, you should enter the following when compiling the `altera_mf` library when RAM Initialization File memory initialization files are used:

```
vlog -work altera_mf altera_mf.v +define+USE_RIF=1
```

For the Quartus II software versions 5.0 and earlier, you must define the **NO\_PLI** macro instead of **USE\_RIF**. The **NO\_PLI** macro is forward compatible with the Quartus II software.

## Post-Synthesis Simulation

A post-synthesis simulation verifies the functionality of a design after synthesis has been performed. You can create a post-synthesis netlist in the Quartus II software and use this netlist to perform a post-synthesis simulation in ModelSim. Once the post-synthesis version of the design is verified, the next step is to place-and-route the design in the target device using the Quartus II Fitter.

### Generating a Post-Synthesis Simulation Netlist

The following steps describe the process of generating a post-synthesis simulation netlist in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to Start and click **Start Analysis and Synthesis** (you can also perform this after step 2).
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
  - a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
  - b. In the **Category** list, select **Simulation**. The **Simulation** page appears.
  - c. In the **Tool name** list:
    - If you are using the ModelSim-Altera software, select **ModelSim-Altera**.
    - If you are using the Mentor Graphics ModelSim software, select **ModelSim**.
  - d. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
  - e. Click **More Settings**. The **More EDA Tools Simulation Settings** dialog box appears. In the **Existing options settings list**, click **Generate Netlist for Functional Simulation Only** and select **On** from the **Setting** list under **Option**.
  - f. Click **OK**.
  - g. In the **Settings** dialog box, click **OK**.

3. Run the EDA Netlist Writer. On the Processing menu, point to Start and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (.vo) or VHDL Output File (.vho) that can be used for post-synthesis simulations in the ModelSim software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the `<project directory>/simulation/modelsim` directory.

## Simulating VHDL Designs

The following instructions help you perform a post-synthesis simulation for a VHDL design in the ModelSim software.

The following steps assume you have already created a ModelSim project.

If you are using the ModelSim-Altera software, a set of precompiled libraries are created when you install the software. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to [“Compile Testbench and Design Files into Work Library” on page 2–9](#).

### *Create Simulation Libraries*

Simulation libraries are required to simulate a design that is mapped to post-synthesis primitives. If you are using the Mentor Graphics ModelSim software, you must create the simulation libraries and correctly link them to your design.

This process is not required with the ModelSim-Altera version because a set of pre-compiled libraries is installed with the software.

### **Create Simulation Libraries Using the ModelSim GUI**

Perform the following steps to create simulation libraries:

1. On the File menu, click **New Library**. The **Create a New Library** dialog box appears.
2. Select **a new Library and a logical linking to it**.
3. In the **Library Name** box, type the name of the newly created library.

4. Click **OK**.

### Create Simulation Libraries Using the ModelSim Command Prompt

Type the following commands to create simulation libraries:

```
vlib <device family name> ↵  
vmap <device family name> <device family name> ↵
```

For more information about library names, refer to [Table 2–9 on page 2–28](#).

### Compile Simulation Models into Simulation Libraries Using the ModelSim GUI

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, point to Add to Project and click **Existing File**.
2. Browse to the <Quartus II installation directory>/eda/sim\_lib directory and add the necessary gate-level simulation files to your project.
3. Select the simulation model file and on the View menu, click **Properties**.
4. In the **Compile to Library** list, select the correct library.
5. Click **OK**.
6. On the Compile menu, click **Compile selected**.

### Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vcom -work <device family name> <Quartus II installation directory> \  
/eda/sim_lib/<device family name>_atoms.vhd ↵  
  
vcom -work <device family name> <Quartus II installation directory> \  
/eda/sim_lib/<device family name>_components.vhd ↵
```

### Compile Testbench and VHDL Output File into Work Library

To compile the testbench and VHDL Output Files into a work library, on the Compile menu, click **Compile All** or click the **Compile All** toolbar icon on the Compile menu.

### Compile Testbench and VHDL Output File into Work Library Using ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vcom -work work <my_test_bench.vhd> <my_vhdl_output_file.vho>↵
```

Resolve any compilation errors before proceeding to the following section.

### Loading the Design

Perform the following steps to load a design:

1. On the Simulate menu, click **Simulate**.
2. Click the **Design** tab.
3. In the **Library** list, select the **work** library.
4. In the **Simulate** dialog box, expand the **work** library and select the top-level design unit (your testbench).
5. Click **OK**.

### Loading the Design Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vsim work.<my test bench> -t 1ps ↵
```

Set the time scale resolution to 1 ps when simulating Altera FPGA designs.

### Running the Simulation

Perform the following steps to run a simulation:

1. On the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag the signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ↵
```

### Running the Simulation Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ␣  
run <time period> ␣
```

## Simulating Verilog HDL Designs

The following sections provide step-by-step instructions for performing post-synthesis simulation for Verilog HDL designs in the ModelSim software.

### Create Simulation Libraries

The following steps assume you have already created a ModelSim project.

If you are using the ModelSim-Altera software, a set of precompiled libraries are created when you install the software. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to [“Compile Testbench and Design Files into Work Library” on page 2-9](#).

### Create Simulation Libraries Using the ModelSim GUI

Perform the following steps to create simulation libraries:

1. In the ModelSim software, on the File menu, point to New and click **Library**. The **Create a New Library** dialog box appears.
2. Select **a new library and a logical mapping to it**.

The name of the libraries should be **altera\_mf** (for Altera megafunctions) and **lpm** (for lpm and MegaWizard Plug-in Manager-generated entities).

3. In the **Library Name** box, type the name of the newly created library.
4. Click **OK**.

### Create Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vlib <device family name> ␣  
vmap <device family name> <device family name> ␣
```

For more information about library names, refer to [Table 2-9 on page 2-28](#).

### Compile Simulation Models into Simulation Libraries Using the ModelSim GUI

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, click **Add to Project**, then select **Existing File**.
2. Browse to the *<Quartus II installation directory>/eda/sim\_lib* directory and add the necessary simulation model files to your project.
3. Select the simulation model file and on the View menu, click **Properties**.
4. Specify the correct library in the **Compile to Library** box.

### Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vlog -work <device family name> <Quartus II installation \
directory> /eda/sim_lib/<device family name>_atoms.v ←
```

### *Compile Testbench and Verilog Output File into Work Library*

To compile the testbench and Verilog Output Files into a work library, on the Compile menu, click **Compile All** or click the **Compile All** toolbar icon on the Compile menu.

### Compile Testbench and Verilog Output File into Work Library Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vlog -work work <my_test_bench.v> <my_verilog_output_file.vo> ←
```

Resolve any compilation errors before proceeding to the following section.

### *Loading the Design*

Perform the following steps to load a design:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Libraries** tab.
3. In the **Search Libraries** box, click **Add**.
4. Specify the location of the device family simulation libraries.
5. In the **Load Design** dialog box, click the **Design** tab and expand the work library.
6. Select the top-level design unit (your testbench).
7. In the **Resolution** list, select **ps**.
8. Click **OK**.

### **Loading the Design Using the ModelSim Command Prompt**

Type the following command at the ModelSim command prompt:

```
vsim -L <gate-level simulation library> work.<my_test_bench> -t 1ps ←
```

Set the time scale resolution to 1 ps when simulating Altera FPGA designs.

### *Running the Simulation*

Perform the following steps to run a simulation:

1. In the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag the signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ←
```

## Gate-Level Timing Simulation

### Running the Simulation Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ←  
run <time period> ←
```

Gate-level timing simulation is a post place-and-route simulation to verify the operation of the design after the worst-case timing delays have been calculated. This section provides detailed instructions on how to perform gate-level timing simulation in the ModelSim-Altera software and highlights differences in performing similar steps in the Mentor Graphics ModelSim software versions for VHDL and Verilog HDL designs.

### Generating a Gate-Level Timing Simulation Netlist

To perform gate-level timing simulation, the ModelSim-Altera software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a Verilog Output File for Verilog HDL designs and a VHDL Output File for VHDL designs. The accompanying timing information is stored in the Standard Delay Format Output File (.sdo), which annotates the delay for the elements found in the Verilog Output File or VHDL Output File.

The following steps describe the process of generating a gate-level timing simulation netlist in the Quartus II software:

1. Perform a full compilation. On the Processing menu, click **Start Compilation**.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, click the “+” icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
4. In the **Tool name** list:
  - If you are using the ModelSim-Altera software, select **ModelSim-Altera**.
  - If you are using the Mentor Graphics ModelSim software, select **ModelSim**.

5. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
6. Click **OK**.
7. In the **Settings** dialog box, click **OK**.
8. Run the EDA Netlist Writer. On the Processing menu, point to Start and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (**.vo**), VHDL Output File (**.vho**), and a SDO used for gate-level timing simulations in the ModelSim software. This netlist file is mapped to architecture-specific primitives. The timing information for the netlist is included in the SDO. The resulting netlist is located in the output directory you specified in the Settings dialog box, which defaults to the *<project\_directory>/simulation/modelsim* directory.

### *Generating a Different Timing Model*

If you enable the Quartus II Classic or Quartus II TimeQuest Timing Analyzer when generating the SDO file, slow-corner (worst case) timing models are used by default. To generate the SDO file using a different timing model, you must run the Quartus II Classic or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to Start and click **Start Classic Timing Analyzer (Fast Timing Model)**. After timing analysis is complete, the Compilation Report appears. You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the `-fast_model` option after you create the timing netlist. The following command enables the fast timing models:

```
create_timing_netlist -fast_model ↵
```

You can also type the following command at a command prompt:

```
quartus_sta <project_name> --fast_model=on ↵
```

For more information about generating the timing model, refer to the *Quartus II Classic Timing Analyzer* or *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

After you run the Classic or TimeQuest Timing Analyzer, you can perform steps 2 through 8 in “[Generating a Gate-Level Timing Simulation Netlist](#)” on page 2–23 to generate the SDO file. For fast corner timing models, the `_fast` post fix is added to the VO, VHO, and SDO file (for example, `my_project_fast.vo`, `my_project_fast.vho`, and `my_project_fast.sdo`).

### Operating Condition Example: Generate All Timing Models for Stratix III Devices

In Stratix III and Cyclone III devices, you can specify different temperature and voltage parameters to generate the timing models. [Table 2–7](#) shows the available operation conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Device Family	Model	Voltage	Temperature
Stratix III	Slow	1100 mV	85° C
	Slow	1100 mV	0° C
	Fast	1100 mV	0° C
Cyclone III	Slow	1200 mV	85° C
	Slow	1200 mV	0° C
	Fast	1200 mV	0° C

To generate the SDO files for the three different operating conditions for a Stratix III design, perform the following steps:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ←
```

2. Generate the ModelSim simulation output files for all three corners specified above. The output files are generated in the simulation output directory. Type the following command at a command prompt:

```
quartus_eda <project name> --simulation --tool=modelsim --format=verilog ←
```

To summarize, for the three operating conditions the preceding steps generate the following files in the simulation output directory:

First slow corner (slow, 1100 mV, 85° C):

VO file— *<revision name>.vo*

SDO file— *<revision name>\_v.sdo*

Second slow corner (slow, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_slow.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_slow.sdo*

Fast corner (fast, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_fast.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_fast.sdo*

### *Perform Timing Simulation Using Post-synthesis Netlist*

Instead of using the gate-level netlist, you can also perform a timing simulation with the post-synthesis netlist. You can generate a SDO without running the fitter. In this case, the SDO file includes all timing values for only the device cells. Interconnect delays are not included because fitting (placement and routing) has not been performed.

To generate the post-synthesis netlist and the SDO file, type the following command at a command prompt:

```
quartus_map <project name> -c <revision name> ␣
quartus_tan <project name> -c <revision name> --post_map --zero_ic_delays ␣
quartus_eda <project name> -c <revision name> --simulation --tool= \
<3rd party EDA tool> --format=<HDL language> ␣
```

For more information on the --format and --tool options, type the following command at a command prompt:

```
quartus_eda -help=<options> ␣
```

## Gate-Level Simulation Libraries

Table 2–8 provides a description of the ModelSim-Altera precompiled device libraries.

<i>Table 2–8. ModelSim-Altera Precompiled Device Libraries</i>	
<b>Library</b>	<b>Description</b>
<b>arriagx_hssi</b>	Precompiled library for Arria® GX device designs using the Gigabit Transceiver Block (alt2gxb megafunction). This precompiled library is required for both functional and timing simulations.
<b>stratixiii</b>	Precompiled library for Stratix® III device designs.
<b>stratixii</b>	Precompiled library for Stratix II device designs.
<b>stratixiigx</b>	Precompiled library for Stratix II GX device designs.
<b>stratixiigx_hssi</b>	Precompiled library for Stratix II GX device designs using the Gigabit Transceiver Block (alt2gxb megafunction). This precompiled library is required for both functional and timing simulations.
<b>stratix</b>	Precompiled library for Stratix device designs.
<b>stratixgx</b>	Precompiled library for Stratix GX device designs.
<b>stratixgx_gxb</b>	Precompiled library for Stratix GX device designs using the Gigabit Transceiver Block. This precompiled library should be used for post-fit (timing) simulations.
<b>altgxb</b>	Precompiled library for Stratix GX device designs that include the altgxb megafunction. This precompiled library should be used for functional simulations.
<b>cycloneii</b>	Precompiled library for Cyclone® II device designs.
<b>cyclone</b>	Precompiled library for Cyclone device designs.
<b>maxii</b>	Precompiled library for MAX® II device designs.
<b>max</b>	Precompiled library for MAX 7000 and MAX 3000 device designs.
<b>apexii</b>	Precompiled library for APEX™ II device designs.
<b>apex20k</b>	Precompiled library for APEX 20K device designs.
<b>apex20ke</b>	Precompiled library for APEX 20KC, APEX 20KE, and Excalibur™ device designs.
<b>mercury</b>	Precompiled library for Mercury™ device designs.
<b>flex10ke</b>	Precompiled library for FLEX® 10KE and ACEX® 1K device designs.
<b>flex6000</b>	Precompiled library for FLEX 6000 device designs.

Table 2–9 shows the location of the timing simulation libraries in the ModelSim-Altera software for Verilog HDL.

Library	Verilog HDL
arriagx_ver	<ModelSim-Altera installation directory>\altera\verilog\arriagx\
arriagx_hssi_ver	<ModelSim-Altera installation directory>\altera\verilog\arriagx_hssi\ (1)
stratixii_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixii\
stratixiigx_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixiigx\
stratixiigx_hssi_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixiigx_hssi\ (1)
stratixiii_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixiii\
stratix_ver	<ModelSim-Altera installation directory>\altera\verilog\stratix\
stratixgx_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixgx\
stratixgx_gxb_ver	<ModelSim-Altera installation directory>\altera\verilog\stratixgx_gxb\

flex6000	<ModelSim-Altera installation directory>\altera\vhdl\flex6000\
mercury	<ModelSim-Altera installation directory>\altera\vhdl\mercury\

Note to [Table 2–10](#):

- (1) The `stratixiigx_hssi` precompiled library is required for functional and timing simulations.

If you are using the Mentor Graphics ModelSim software version for your timing simulation, libraries are available in the Quartus II software in the <Quartus II installation directory>\eda\sim\_lib\ directory. Mentor Graphics ModelSim software users must use the files provided with the Quartus II software.

## Simulating VHDL Designs

The following section provides step-by-step instructions for performing gate-level timing simulation for VHDL designs. The following steps assume you have already created a ModelSim project. For additional information, refer to “Altera Design Flow with ModelSim or ModelSim-Altera Software” on page 2–3.

If you are using the ModelSim-Altera software, a set of precompiled libraries are created when you install the software. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to “[Compile Testbench and Design Files into Work Library](#)” on page 2–9.

### *Create Simulation Libraries*

If you are using the Mentor Graphics ModelSim software, create the gate-level simulation libraries and correctly link them to your design.

#### **Create Simulation Libraries Using the ModelSim GUI**

Perform the following steps to create simulation libraries:

1. In the ModelSim software, on the File menu, point to New and click **Library**. The **Create a New Library** dialog box appears.
2. Select **a new library and a logical mapping to it**.

The name of the libraries should be **altera\_mf** (for Altera megafunctions) and **lpm** (for lpm and MegaWizard Plug-In Manager-generated entities).

3. In the **Library Name** box, type the name of the newly created library.

The library name must be one of those listed in [Table 2–10 on page 2–28](#).

4. Click **OK**.

**Create Simulation Libraries Using the ModelSim Command Prompt**

Type the following commands at the ModelSim command prompt:

```
vlib <device family name> ␣
vmap <device family name> <device family name> ␣
```

For more information about library names, refer to [Table 2–9 on page 2–28](#).

**Compile Simulation Models into Simulation Libraries Using the ModelSim GUI**

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, point to Add to Project and click **Existing File**.
2. Browse to the *<Quartus II installation directory>/eda/sim\_lib* directory, and add the necessary gate-level simulation files to your project.
3. Select the simulation model file, and on the View menu, click **Properties**.
4. In the **Compile to Library** list, select the correct library.
5. Click OK.
6. On the Compile menu, click **Compile selected**.

**Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt**

Type the following commands at the ModelSim command prompt:

```
vcom -work <device family name> <Quartus II installation directory> \
/eda/sim_lib/<device family name>_atoms.vhd ␣

vcom -work <device family name> <Quartus II installation directory> \
/eda/sim_lib/<device family name>_components.vhd ␣
```

*Compile Testbench and VHDL Output File into Work Library*

Compile testbench and VHDL Output Files into a work library on the Compile menu by clicking **Compile All** or by clicking the **Compile All** toolbar icon on the Compile menu.

### Compile Testbench and VHDL Output File into Work Library Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vcom -work work <my_test_bench.vhd> <my_vhdl_output_file.vho> ↵
```

Resolve any compilation errors before proceeding to the following section.

### *Loading the Design*

Perform the following steps to load a design:

1. On the Simulate menu, click **Start Simulation**.
2. Click the **SDF** tab, and click **Add**.
3. In the **Add SDF Entry** dialog box, click **Browse** and select the Standard Delay Format Output File (**.sdo**).
4. In the **Apply to Region** dialog box, type in the instance path to which the SDO should be applied. For example, if you are using a testbench exported into the Quartus II software from a Vector Waveform File, the instance path should be set to `/i1`.

You do not have to choose from the **Delay** list because the Quartus II EDA Netlist Writer generates the SDO using the same value for the triplet (minimum, typical, and maximum timing values). The value is derived from either the fast (minimum) timing model or worst case (maximum) timing model, depending on which timing model was used in the last timing analysis. In the standard compilation flow, the Quartus II software writes the SDO using timing values from the worst case (maximum) timing model.

5. Click **OK**.
6. Click the **Design** tab. In the **Resolution** list, select **ps**.
7. In the **Library** list, select the **work** library.
8. In the **Start Simulation** dialog box, expand the **work** library.
9. Select the top-level design unit (your testbench).
10. Click **OK**.

**Loading a Design Using the ModelSim Command Prompt**

Type the following command at the ModelSim command prompt:

```
vsim -sdftyp <instance path to design>=<path to SDO> work. \
<my_test bench> -t ps ↵
```

**Running the Simulation**

Perform the following steps to run a simulation:

1. In the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag the signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ↵
```

**Running a Simulation Using the ModelSim Command Prompt**

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ↵
run <time period> ↵
```

**Simulating Verilog HDL Designs**

The following sections provide step-by-step instructions on performing gate-level timing simulation for Verilog HDL designs in the ModelSim-Altera software.

If you are using the ModelSim-Altera software, a set of pre-compiled libraries are created when you install the software. Creating simulation libraries and compiling simulation models steps are not required. You can proceed directly to [“Compile Testbench and Design Files into Work Library”](#) on page 2–9.

**Create Simulation Libraries**

If you are using the Mentor Graphics ModelSim software, you must create the simulation libraries and correctly link them to your design.

The following steps assume you have already created a ModelSim project. For additional information, refer to “[Altera Design Flow with ModelSim or ModelSim-Altera Software](#)” on page 2–3.

### Create Simulation Libraries Using the ModelSim GUI

Perform the following steps to create simulation libraries:

1. In the ModelSim software, on the File menu, point to New and click **Library**. The **Create a New Library** dialog box appears.
2. Select **a new library and a logical mapping to it**.

The names of the libraries should be **altera\_mf** (for Altera megafunctions) and **lpm** (for lpm and MegaWizard Plug-In Manager-generated entities).

3. In the **Library Name** box, type the name of the newly created library.
4. Click **OK**.

### Create Simulation Libraries Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
vlib <library name> ←  
vmap <library name> <device family name> ←
```

For more information about library names, refer to [Table 2–9 on page 2–28](#).

### Compile Simulation Models into Simulation Libraries Using the ModelSim GUI

Perform the following steps to compile simulation models into simulation libraries:

1. On the File menu, point to Add to Project and click **Existing File**.
2. Browse to the `<Quartus II installation directory>/eda/sim_lib`, and add the necessary simulation model files to your project.
3. Select the simulation model file, and on the View menu, click **Properties**.
4. In the **Compile to Library** list, select the correct library.

5. Click **OK**.
6. On the Compile menu, click **Compile selected**.

### Compile Simulation Models into Simulation Libraries Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vlog -work <device family name> <Quartus II installation directory> /eda/sim_lib/<device family name> \
_atoms.v ←
```

### Compile Testbench and Verilog Output File into Work Library

Compile a testbench and Verilog Output File into a work library on the Compile menu by clicking **Compile All** or by clicking the **Compile All** toolbar icon on the Compile menu.

### Compile Testbench and Verilog Output File into Work Libraries Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vlog -work work <my_test_bench.v> <my_verilog_output_file.vo> ←
```

Resolve any compilation errors before proceeding to the following section.

### Loading the Design

Perform the following steps to load a design:

1. On the Simulate menu, click **Start Simulation**. The **Start Simulation** dialog box appears.
2. Click the **Libraries** tab.
3. In the **Search Libraries** box, click **Add**.
4. Specify the location of the **lpm** or **altera\_mf** simulation libraries.

If you are using the ModelSim-Altera version, refer to [Table 2-3 on page 2-5](#) and [Table 2-4 on page 2-6](#) for the location of the precompiled simulation libraries. If you are using the Mentor Graphics ModelSim software version, browse to the library that you created earlier.

5. In the **Load Design** dialog box, click the **Design** tab and expand the work library.

6. Select the top-level design unit (your testbench).
7. In the **Resolution** list, select **ps**.
8. Click **OK**.

When simulating in Verilog HDL, the SDO does not have to be manually specified because in the Quartus II generated Verilog Output File, there is a `$sdf_annotate` task that ModelSim uses to look into the current directory from which VSIM was run and uses to look for the SDO. If your SDO is not in the same directory from which you ran VSIM, you can either copy the SDO into your current directory or comment out the `$sdf_annotate` line in the Verilog Output File and manually specify the SDO in the Load Design dialog box.

### Loading the Design Using the ModelSim Command Prompt

Type the following command at the ModelSim command prompt:

```
vsim -L <location of the gate level simulation library> -work .<my_test_bench> -t ps ↵
```

### Running the Simulation

Perform the following steps to run a simulation:

1. On the View menu, point to Debug Windows and click **Objects**. This command displays all objects in the current scope.
2. On the View menu, point to Debug Windows and click **Wave**.
3. Drag the signals to monitor from the Objects window and drop them into the Wave window.
4. Type the following command at the ModelSim command prompt:

```
run <time period> ↵
```

### Running the Simulation Using the ModelSim Command Prompt

Type the following commands at the ModelSim command prompt:

```
add wave /<signal name> ↵  
run <time period> ↵
```

For the design examples to run gate-level timing simulation in VHDL or Verilog language, refer to:

[www.altera.com/support/examples/modelsim/exm-modelsim.html](http://www.altera.com/support/examples/modelsim/exm-modelsim.html).

## Simulating Designs that Include Transceivers

If your design includes a Stratix GX or Stratix II GX transceiver, you must compile additional library files to perform functional or timing simulations.

### Stratix GX Functional Simulation

To perform a functional simulation of your design that instantiates the `altgxb` megafunction which enables the gigabit transceiver block on Stratix GX devices, compile the `stratixgx_mf` model file into the `altgxb` library.

The `stratixii_gx_mf` model file references the `lpm` and `sgate` libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

#### *Example: Performing Functional Simulation for Stratix GX in Verilog HDL*

If you are using ModelSim-Altera, compiling the libraries is not necessary. You can simulate the design directly by typing the following command:

```
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L altgxb work.<my design> ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vlib work ↵
vlib lpm ↵
vlib altera_mf ↵
vlib sgate ↵
vlib altgxb ↵
vlog -work lpm 220model.v ↵
vlog -work altera_mf altera_mf.v ↵
vlog -work sgate sgate.v ↵
vlog -work altgxb stratixgx_mf.v ↵
vsim -L lpm -L sgate -L altgxb work.<my design> ↵
```

#### *Example: Performing Functional Simulation for Stratix GX in VHDL*

If you are using ModelSim-Altera, compiling the libraries is not necessary and you can simulate the design directly by typing the following command:

```
vsim -L lpm -L sgate -L altgxb work.<my design> r ↵
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulation the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ␣
vcom -work lpm 220pack.vhd 220model.vhd ␣
vcom -work sgate sgate_pack.vhd sgate.vhd ␣
vcom -work altgxb stratixgx_mf.vhd stratixgx_mf_components.vhd ␣
vsim -L lpm -L altera_mf -L sgate -L altgxb work.<my design> ␣
```

## Stratix GX Post-Fit (Timing) Simulation

Perform a post-fit timing simulation of your design that includes a Stratix GX transceiver by compiling the **stratixgx\_atoms** and **stratixgx\_hssi\_atoms** model files into the **stratixgx** and **stratixgx\_gxb** libraries, respectively.

The **stratixgx\_hssi\_atoms** model file references the **lpm** and **sgate** libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

### *Example: Performing Timing Simulation for Stratix GX in Verilog HDL*

If you are using ModelSim-Altera, compiling the libraries is not necessary. You can simulate the design directly by typing the following command:

```
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver -L \
stratixgx_gxb work.<my design> -t ps +transport_int_delays \
+transport_path_delays ␣
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vlog -work lpm 220model.v ␣
vlog -work altera_mf altera_mf.v ␣
vlog -work sgate sgate.v ␣
vlog -work stratixgx stratixgx_atoms.v ␣
vlog -work stratixgx_gxb stratixgx_hssi_atoms.v ␣
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
work.<my design> -t ps +transport_int_delays +transport_path_delays ␣
```

This example assumes you are using ModelSim PE/SE. If you are using ModelSim-Altera, type the following command to simulate your design:

```
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_ver -L \
stratixgx_gxb work.<my design> -t ps +transport_int_delays \
+transport_path_delays ←
```

### Example: Performing Timing Simulation for Stratix GX in VHDL

If you are using ModelSim-Altera, compiling the libraries is not necessary. You can simulate the design directly by typing the following command:

```
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
work. <my design> -t ps - +transport_int_delays+transport_path_delays ←
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vcom -work lpm 220pack.vhd 220model.vhd ←
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ←
vcom -work sgate sgate_pack.vhd sgate.vhd ←
vcom -work stratixgx stratixgx_atoms.vhd stratixgx_components.vhd ←
vcom -work stratixgx_gxb stratixgx_hssi_atoms.vhd \
stratixgx_hssi_components.vhd ←
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
work. <my design> -t ps +transport_int_delays +transport_path_delays ←
```

This example assumes you are using ModelSim PE/SE. If you are using ModelSim-Altera, type the following command to simulate your design:

```
vsim -L lpm -L altera_mf -L sgate -L stratixgx -L stratixgx_gxb \
work. <my design> -t ps - +transport_int_delays+transport_path_delays ←
```

## Stratix II GX Functional Simulation

To perform a functional simulation of your design that instantiates the `alt2gxb` megafunction, which enables the gigabit transceiver block on Stratix II GX devices, compile the `stratixiigx_hssi` model file into the `stratixiigx_hssi` library.

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

```
vsim -L lpm_ver -L altera_mf_ver -L sgate_ver -L stratixgx_hssi_ver \
work.<my design> ←
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vlog -work lpm 220model.v ←
vlog -work altera_mf altera_mf.v ←
vlog -work sgate sgate.v ←
vlog -work stratixiigx_hssi stratixiigx_hssi_atoms.v ←
vlog -work work <alt2gxb module name>.vo ←
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my design> ←
```

### Example: Performing Functional Simulation for Stratix II GX in VHDL

If you are using ModelSim-Altera, compiling the libraries is not necessary. You can simulate the design directly by typing the following command:

```
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my design> r ←
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vcom -work lpm 220pack.vhd 220model.vhd ←
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ←
vcom -work sgate sgate_pack.vhd sgate.vhd ←
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd ←
vcom -work work <alt2gxb entity name>.vho ←
vsim -L lpm -L altera_mf -L sgate -L stratixgx_hssi work.<my design> ←
```

## Stratix II GX Post-Fit (Timing) Simulation

To perform a post-fit timing simulation of your design that includes a Stratix II GX transceiver, compile `stratixiigx_atoms` and `stratixiigx_hssi_atoms` into the `stratixiigx` and `stratixiigx_hssi` libraries, respectively.

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries. If you are using ModelSim PE/SE, you must create these libraries to perform a simulation.

*Example: Performing Timing Simulation for Stratix II GX in Verilog HDL*

If you are using ModelSim-Altera, compiling the libraries is not necessary and you can simulate the design directly by typing the following command:

```
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \  
work.<my design> -t ps +transport_int_delays +transport_path_delays ␣
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vlog -work lpm 220model.v ␣  
vlog -work altera_mf altera_mf.v ␣  
vlog -work sgate sgate.v ␣  
vlog -work stratixiigx stratixiigx_atoms.v ␣  
vlog -work stratixiigx_hssi stratixiigx_hssi_atoms.v ␣  
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \  
work.<my design> -t ps +transport_int_delays +transport_path_delays ␣
```

*Example: Performing Timing Simulation for Stratix II GX in VHDL*

If you are using ModelSim-Altera, compiling the libraries is not necessary. You can simulate the design directly by typing the following command:

```
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \  
work.<my design> -t ps +transport_int_delays +transport_path_delays ␣
```

If you are using ModelSim SE/PE, you must compile the necessary libraries before you can simulate the designs. Type the following commands at the ModelSim command prompt to compile and simulate the design:

```
vcom -work lpm 220pack.vhd 220model.vhd ␣  
vcom -work altera_mf altera_mf_components.vhd altera_mf.vhd ␣  
vcom -work sgate sgate_pack.vhd sgate.vhd ␣  
vcom -work stratixiigx stratixiigx_atoms.vhd stratixiigx_components.vhd ␣  
vcom -work stratixiigx_hssi stratixiigx_hssi_components.vhd \  
stratixiigx_hssi_atoms.vhd ␣  
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \  
work.<my design> -t ps +transport_int_delays +transport_path_delays ␣
```

This example assumes you are using ModelSim PE/SE. If you are using ModelSim-Altera, you do not need to compile any libraries and can type the following command:

```
vsim -L lpm -L altera_mf -L sgate -L stratixiigx -L stratixiigx_hssi \
work.<my design> -t ps +transport_int_delays +transport_path_delays ←
```

## Transport Delays

By default, the ModelSim software filters out all pulses that are shorter than the propagation delay between primitives. Turning on the transport delay options in the ModelSim software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

### *+transport\_path\_delays*

Use this option when the pulses in your simulation may be shorter than the delay within a gate-level primitive.

### *+transport\_int\_delays*

Use this option when the pulses in your simulation may be shorter than the interconnect delay between gate-level primitives.

The *+transport\_path\_delays* and *+transport\_int\_delays* options are also used by default in the NativeLink feature for gate-level timing simulation.

For more information about either of these options, refer to the ModelSim Altera Command Reference installed with the ModelSim software.

The following ModelSim software command describes the command-line syntax to perform a gate-level timing simulation with the device family library:

```
vsim -t lps -L stratixii -sdftyp /il=filtref_vhd.sdo work.filtref_vhd_vec_tst \
+transport_int_delays +transport_path_delays
```

## Using the NativeLink Feature with ModelSim

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run ModelSim within the Quartus II software.

### Setting Up NativeLink

To run ModelSim automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**.
3. Double-click the entry under **Location of executable** beside the name of your EDA Tool.
4. Type or browse to the directory containing the executables of your EDA tool.

For ModelSim-Altera and ModelSim SE/PE, executable files are stored in the **win32aloem** and **win32** directories, respectively.

`c:\<ModelSim-Altera installation path>\win32aloem`

`c:\<ModelSim installation path>\win32`

5. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` TCL command:

```
set_user_option -name EDA_TOOL_PATH_MODELSIM <path to executables>
set_user_option -name EDA_TOOL_PATH_MODELSIM_ALTERA <path to executables>
```

### Performing an RTL Simulation Using NativeLink

To run a functional RTL simulation with the ModelSim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 2-3).

Figure 2–3. Simulation Page in the Settings Dialog Box

- In the **Tool name** list, select one of the following choices:
  - ModelSim
  - ModelSim-Altera
- If your design is written entirely in Verilog HDL or in VHDL, the NativeLink feature automatically chooses the correct language and Altera simulation libraries. If your design is written with mixed languages, the NativeLink feature uses the default language specified in the **Format for output netlist** list. To change the default language when there is a mixed language design, under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. Table 2–11 shows the design languages for output netlists and simulation models.

<b>Design File</b>	<b>Format for Output Netlist</b>	<b>Simulation Models Used</b>
Verilog	Any	Verilog
VHDL	Any	VHDL
Mixed	Verilog	Verilog
Mixed	VHDL	VHDL

For mixed language simulation, choose the same language that was used to generate your megafunctions to ensure correct parameter passing between the megafunctions and the Altera libraries. For example, if your `altsyncram` megafunction was generated in VHDL, choose VHDL as the format for the output netlist.

When creating mixed language designs, it is important to be aware of the following:

- EDA Simulation tools do not allow seamless passing of parameters when a VHDL entity is instantiated in Verilog designs.
  - The ModelSim and ModelSim-Altera software do not allow the use of Verilog User Defined Primitives (UDPs) to be instantiated in VHDL designs.
5. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

For more information about setting up a testbench with NativeLink, refer to [“Setting Up a Testbench” on page 2–48](#).

6. Click **OK**.
7. On the Processing menu, point to Start and click **Start Analysis and Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
8. On the Tools menu, point to **EDA Simulation Tool** and click **Run EDA RTL Simulation** to automatically run ModelSim, compile all necessary design files, and complete a simulation.

## Performing a Gate-Level Simulation Using NativeLink

To run a gate-level timing simulation with the ModelSim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 2-3 on page 2-45).
3. In the **Tool name** list, select one of the following:
  - ModelSim
  - ModelSim-Altera
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, choose **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To run a gate-level simulation after each full compilation, turn on **Run Gate Level Simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. Click **OK**.
8. On the Processing menu, point to Start and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.
9. On the Tools menu, point to EDA Simulation Tool and click **Run EDA Gate Level Simulation** to automatically run ModelSim, compile all necessary design files, and complete a simulation.

A ModelSim Macro File (\*.do) is generated in the `<project_directory>\simulation\modelsim` directory while running NativeLink. You can perform a simulation with the DO file directly from ModelSim when you rerun a simulation without using NativeLink. To perform the simulation directly without NativeLink, type the following command in the ModelSim console: `do <generated_do_file>.do`.

## Setting Up a Testbench

You can use NativeLink to compile your design files and testbench files, and run an EDA simulation tool to automatically perform a simulation.

To set up NativeLink for simulation, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the “+” icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None**, **Compile test bench**, or **Script to compile test bench** (Table 2–12).

**Table 2–12. NativeLink Settings**

Settings	Description
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.
Script to compile test bench	NativeLink compiles the simulation models and design files. The script you provide is sourced after design files compile. Use this option when you want to create your own script to compile your testbench and perform simulation.

4. If you select **Compile test bench**, select your test bench setup from the **Compile test bench** list. You can use different testbench setups to specify different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:
  - a. Click **Test Benches**. The **Test Benches** dialog box appears.
  - b. Click **New**. The **New Test Bench Settings** dialog box appears.
  - c. In the **Test Bench name** box, type in the testbench setup name that identifies the different test bench setups.
  - d. In the **Test bench entity** box, type in the top-level testbench entity name. For example, for a Quartus II generated VHDL testbench, type in `<Vector Waveform File name>_vhd_vec_tst`.
  - e. In the **Instance** box, type in the full instance path to the top level of your FPGA design. For example, for a Quartus II generated VHDL testbench, type in `i.1`.

- f. Under **Simulation period**, select **Run simulation until all vector stimuli are used** or specify the end time of the simulation.
  - g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** button to reorder your files. The script used by NativeLink compiles the files in order from top to bottom.
-  You can also specify the library name and the HDL version to compile the testbench file. Native link compiles the testbench to a library name using the specified HDL version.
- h. Click **OK**.
  - i. In the **Test Benches** dialog box, click **OK**.
5. Under **NativeLink settings**, you can turn on **Use script to setup simulation** and browse to your script. Your script is executed to set up and run simulation after loading the design using the `vsim` command.
  6. If you choose **Script to compile test bench**, browse to your script and click **OK**.

### *Creating a Testbench*

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File. The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your Vector Waveform File.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. Click the **Save as type** arrow and select **VHDL Test Bench File (\*.vht)** or **Verilog Test Bench File (\*.vt)**.
6. You can turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.

7. Click **Export**. Your VHDL or Verilog testbench file is generated in your project directory.

## Scripting Support

You can run procedures and create settings described in this chapter in a Tcl script. You can also run some procedures at the command line prompt.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For detailed information about scripting command options, refer to the **Qhelp** command line and Tcl API help browser.

Type this command to start the Qhelp help browser:

```
quartus_sh --qhelp←
```

### Generating a Post-Synthesis Simulation Netlist for ModelSim

You can use the Quartus II software to generate a post-synthesis simulation netlist with Tcl commands or with a command at the command-line prompt. The following example assumes that you are selecting ModelSim (Verilog HDL output from Quartus II software).

#### *Tcl Commands*

Use the following Tcl commands to set the output format to Verilog HDL, the simulation tool to ModelSim for Verilog HDL, and to generate a functional netlist:

```
set_global_assignment-name EDA_SIMULATION_TOOL "ModelSim (Verilog)"  
set_global_assignment-name EDA_GENERATE_FUNCTIONAL_NETLIST ON
```

#### *Command Prompt*

Use the following command to generate a simulation output file for the ModelSim simulator. Specify VHDL or Verilog HDL for the format:

```
quartus_eda <project name> --simulation=on --format=<format> --tool=ModelSim \  
--functional ←
```

## Generating a Gate-Level Timing Simulation Netlist for ModelSim

You can use the Quartus II software to generate a gate-level timing simulation netlist with Tcl commands or with a command at the command prompt.

### *Tcl Commands*

Use one of the following Tcl commands:

```
set_global_assignment -name EDA_SIMULATION_TOOL "ModelSim-Altera (Verilog) "
set_global_assignment -name EDA_SIMULATION_TOOL "ModelSim-Altera (VHDL) "
set_global_assignment -name EDA_SIMULATION_TOOL "ModelSim (Verilog) "
set_global_assignment -name EDA_SIMULATION_TOOL "ModelSim (VHDL) "
```

### *Command Line*

Generate a simulation output file for the ModelSim simulator by specifying VHDL or Verilog HDL for the format by typing the following command at the command prompt:

```
quartus_eda <project name> --simulation=on --format=<format> --tool=ModelSim ←
```

## Software Licensing and Licensing Setup

License the ModelSim-Altera software with a parallel port software guard (T-guard), USB guard, FIXEDPC license, or a network FLOATNET or FLOATPC license. Each Altera software subscription includes a license for either VHDL or Verilog HDL. Network licenses with multiple users may have their licenses split between VHDL and Verilog HDL in any ratio.

The USB software guard is not supported by versions earlier than Mentor Graphics ModelSim software 5.8d.

Obtain a license for the ModelSim-Altera software from the Altera website at [www.altera.com](http://www.altera.com). Get licensing information for the Mentor Graphics ModelSim software directly from Mentor Graphics. Refer to [Figure 2-4](#) for the set-up process.

For ModelSim-Altera versions prior to 5.5b, use the PCLS utility included with the software to set up the license.

**Figure 2-4. ModelSim-Altera Licensing Set Up Process**

### LM\_LICENSE\_FILE Variable

Altera recommends setting the `LM_LICENSE_FILE` environment variable to the location of the license file.

## Conclusion

Using the ModelSim-Altera simulation software within the Altera FPGA design flow enables Altera software users to easily and accurately perform functional RTL simulations, post-synthesis simulations, and gate-level simulations on their designs. Proper verification of designs at the functional, post-synthesis, and post place-and-route stages using the ModelSim-Altera software helps ensure design functionality and success and, ultimately, a quick time-to-market.

## Document Revision History

Table 2–13 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Updated Table 2–2. Updated “Operating Condition Example: Generate All Timing Models for Stratix III Devices” on page 2–25.	Updated for the Quartus II software version 7.2.
May 2007 v7.1.0	Updated “Functional RTL Simulation” on page 2–5. Updated “Gate-Level Timing Simulation” on page 2–23. Added “Perform Timing Simulation Using Post-synthesis Netlist” on page 2–26. Updated examples in “Simulating Designs that Include Transceivers” on page 2–37. Updated procedures in “Setting Up a Testbench” on page 2–48. Added “Referenced Documents” on page 2–52.	Updated for the Quartus II software version 7.1.
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only.	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>• Added ModelSim-Altera Web Edition to Table 2-1.</li> <li>• Added Stratix III library support to Table 2-8, 2-9, and 2-10.</li> <li>• Other minor changes to chapter.</li> </ul>	Updated for the Quartus II software version 6.1.
May 2006 v6.0.0	Updated for the Quartus II software version 6.0.0: <ul style="list-style-type: none"> <li>• Added a section on setting ModelSim as the Simulation Tool</li> <li>• Updated EDA Tools Settings in the GUI.</li> <li>• Updated the Synopsys Design Constraints File information.</li> <li>• Updated the device information.</li> <li>• Added Quartus II-Generated Testbench information</li> <li>• Updated megafunction information.</li> </ul>	—
October 2005 v5.1.0	Updated for the Quartus II software version 5.1.	—
May 2005 v5.0.0	<ul style="list-style-type: none"> <li>• Updates to tables, figures.</li> <li>• Updated information.</li> <li>• New functionality for Quartus II software 5.0.</li> </ul>	—
December 2004 v3.0	<ul style="list-style-type: none"> <li>• Reorganized chapter, updated information.</li> <li>• Updates to tables, figures.</li> <li>• New functionality for Quartus II software 4.2.</li> </ul>	—
June 2004 v2.0	<ul style="list-style-type: none"> <li>• Updates to tables, figures.</li> <li>• New functionality for Quartus II software 4.1.</li> </ul>	—
February 2004 v1.0	Initial release.	—

## Introduction

This chapter is an overview about using the Synopsys VCS software to simulate designs that target Altera® FPGAs. It provides a step-by-step explanation of how to perform functional register transfer level (RTL) simulations, post-synthesis simulations, and gate-level timing simulations using the VCS software.

This chapter discusses the following topics:

- “Software Requirements”
- “Common VCS Software Compiler Options” on page 3–11
- “Using VirSim” on page 3–12
- “Debugging Support Command-Line Interface” on page 3–12
- “Simulating Designs that Include Transceivers” on page 3–13
- “Using PLI Routines with the VCS Software” on page 3–16
- “Transport Delays” on page 3–17
- “Using NativeLink with the VCS Software” on page 3–18
- “Scripting Support” on page 3–23

## Software Requirements

To simulate your design using VCS, you must first set up the Altera libraries. These libraries are installed with the Quartus II software.

Table 3–1 shows the compatibility between versions of the Quartus II software and the Synopsys VCS software.

**Table 3–1. Supported Quartus II and VCS Software Version Compatibility**

Synopsys	Altera
VCS software version Y-2006.06-SP1	Quartus II software version 7.2
VCS software version 2006.06	Quartus II software version 7.1
VCS software version 2005.06-SP2	Quartus II software version 7.0 and 6.1
VCS software version 2005.06-SP1	Quartus II software version 6.0
VCS software version 7.2	Quartus II software version 5.1
VCS software version 7.2	Quartus II software version 5.0
VCS software version 7.1.1	Quartus II software version 4.2

For more information about installing the software and the directories created during the Quartus II software installation, refer to the *Quartus II Installation and Licensing for Windows* or the *Quartus II Installation and Licensing for UNIX and Linux Workstation* manuals.

## Using VCS in the Quartus II Design Flow

You can perform the following types of simulations using VCS:

- Functional RTL
- Post-synthesis
- Gate-level timing

Figure 3-1 shows the VCS and Quartus II software design flow.

**Figure 3-1. Altera Design Flow with the VCS and Quartus II Software**

## Functional Simulations

Functional RTL simulations verify the functionality of the design before synthesis, placement, and routing. These simulations are independent of any Altera FPGA architecture implementation. Once the HDL designs are verified to be functionally correct, the next step is to synthesize the design and use the Quartus II software to place-and-route the design in an Altera device.

To functionally simulate an Altera FPGA design in the VCS software that uses Altera intellectual property (IP) megafunctions, or library of parameterized modules (LPM) functions, you must include certain libraries during the compilation. Table 3–2 summarizes the Verilog HDL library files that are required to compile LPM functions and Altera megafunctions.

Library Name	Verilog HDL Libraries
LPM	220model.v
altera_mf	altera_mf.v
altgxb	stratixgx_mf.v (1)
alt2gxb	stratixiigx_hssi_atoms.v (1) arriagx_hssi_atoms.v (1)
sgate	sgate.v
altera	altera_primitives.v

**Note to Table 3–2:**

- (1) The `stratixgx_mf.v`, `stratixiigx_hssi_atoms.v`, and `arriagx_hssi_atoms.v` library files require the LPM and SGATE libraries.

The library files in Table 3–2 are installed with the Quartus II software. These files are found in the `<path to Quartus II installation>\eda\sim_lib` directory.

The following is a VCS command for performing a functional RTL simulation with one of the libraries in Table 3–2:

```
vcs -R <test bench> .v <design name> .v -v <library file> .v ↵
```

### *Megafunctions Requiring Atom Libraries*

The following Altera megafunctions require gate-level libraries to perform a functional simulation in a third-party simulator:

- altclkbuf
- altclkctrl
- altdq
- altdqs
- altddio\_in
- altddio\_out
- altddio\_bidir
- altufm\_none
- altufm\_parallel
- altufm\_spi
- altmemmult
- altremote\_update

The gate-level library files are located in *<path to Quartus II installation>eda/sim\_lib* directory (Table 3-3).

### *Functional RTL Simulation with Altera Memory Blocks*

The VCS software supports functional simulation of complex Altera memory blocks such as lpm\_ram\_dp and altsyncram. You can create these memory blocks with the Quartus II MegaWizard® Plug-In Manager, which can be initialized with power-up data via a Hexadecimal (Intel-Format) File (.hex) or Memory Initialization File (.mif). The lpm\_file parameter included in the file generated by the MegaWizard Plug-In Manager points to the path of the Hexadecimal (Intel-Format) File or Memory Initialization File that is used to initialize the memory block. You can create a Hexadecimal (Intel-Format) File or Memory Initialization File with the Quartus II software.

### **Compiling Functional Library Files with Compiler Directives**

If you use a Hexadecimal (Intel-Format) File, no compiler directives are required. If you use a RAM Initialization File, the USE\_RIF macro must be defined to compile the model library files. For example, enter the following when compiling the altera\_mf library using RIF memory initialization files:

```
vcs -R -v <path to Quartus installation> /
\eda\sim_lib\altera_mf.v <test bench file> /
<design file (top-level)> +define+USE_RIF=1 ←
```

For the Quartus II software versions 5.0 and earlier, the `NO_PLI` macro must be defined instead of `USE_RIF`. The `NO_PLI` macro is forward compatible with the Quartus II software.

## Post-Synthesis Simulation

A post-synthesis simulation verifies the functionality of a design after synthesis has been performed. You can create a post-synthesis netlist in the Quartus II software and use this netlist to perform a post-synthesis simulation in the VCS software. Once the post-synthesis version of the design has been verified, the next step is to place-and-route the design in the target architecture using the Quartus II software.

### *Generating a Post-Synthesis Simulation Netlist*

The following steps describe the process of generating a post-synthesis simulation netlist in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to Start and click **Start Analysis and Synthesis**.
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
  - a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
  - b. In the **Category** list, select **Simulation**. The **Simulation** page is shown.
  - c. In the **Tool name** list, select **VCS**.
  - d. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
  - e. Click **More Settings**. The **More EDA Tools Simulation Settings** dialog box appears. In the **Existing options settings list**, click **Generate Netlist for Functional Simulation Only** and select **On** from the **Setting** list under **Option**.
  - f. Click **OK**.
  - g. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to Start and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (.vo) that can be used for the post-synthesis simulations in the VCS software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage.

The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the *<project directory>/simulation/vcs* directory. This netlist, along with the device family library listed in [Table 3–3](#), can be used to perform a post-synthesis simulation in the VCS software.

<b>Library Files</b>	<b>Description</b>
<b>arriagx_atoms.v</b> <b>arriagx_hssi_atoms.v</b>	Atom libraries for Arria™ GX designs
<b>stratixii_atoms.v</b>	Atom libraries for Stratix® II designs
<b>stratixiigx_atoms.v</b> <b>stratixiigx_hssi_atoms.v</b>	Atom libraries for Stratix II GX designs
<b>stratix_atoms.v</b>	Atom libraries for Stratix designs
<b>stratixgx_atoms.v</b> <b>stratixgx_hssi_atoms.v</b>	Atom libraries for Stratix GX designs
<b>stratixiii_atoms.v</b>	Atom libraries for Stratix III designs
<b>hardcopyii_atoms.v</b>	Atom libraries for HardCopy® II designs
<b>hcstratix_atoms.v</b>	Atom libraries for HardCopy Stratix designs
<b>cycloneiii_atoms.v</b>	Atom libraries for Cyclone® III designs
<b>cycloneii_atoms.v</b>	Atom libraries for Cyclone II designs
<b>cyclone_atoms.v</b>	Atom libraries for Cyclone designs
<b>apexii_atoms.v</b>	Atom libraries for APEX™ II designs
<b>apex20ke_atoms.v</b>	Atom libraries for APEX 20KE, APEX 20KC, and Excalibur™ designs
<b>apex20k_atoms.v</b>	Atom libraries for APEX 20K designs
<b>flex10ke_atoms.v</b>	Atom libraries for FLEX® 10KE and ACEX® 1K designs
<b>flex6000_atoms.v</b>	Atom libraries for FLEX 6000 designs
<b>maxii_atoms.v</b>	Atom libraries for MAX® II designs
<b>max_atoms.v</b>	Atom libraries for MAX 3000 and MAX 7000 designs
<b>mercury_atoms.v</b>	Atom libraries for Mercury™ designs

The following VCS software commands describe the command-line syntax used to perform a post-synthesis simulation with the appropriate device family library listed in [Table 3-3](#):

```
vcs -R <test bench> <post synthesis netlist> -v <altera device family library> ←
```

## Gate-Level Timing Simulation

A gate-level timing simulation verifies the functionality of the design after place-and-route. You can create a post-fit netlist in the Quartus II software and use this netlist to perform a gate-level timing simulation in VCS software.

## Generating a Gate-Level Timing Simulation Netlist

To perform gate-level timing simulation, the VCS software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a Verilog Output File for Verilog HDL designs. The accompanying timing information is stored in the Standard Delay Output File (.sdo), which annotates the delay for the elements found in the Verilog Output File.

The following steps describe the process of generating a gate-level timing simulation netlist in the Quartus II software:

1. Perform a full compilation. On the Processing menu, click **Start Compilation**.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulation**. The **Simulation** page is shown.
4. In the **Tool name** list, select **VCS**.
5. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
6. Click **OK**.
7. In the **Settings** dialog box, click **OK**.
8. Run the EDA Netlist Writer. On the Processing menu, point to **Start** and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (.vo) that can be used for post-synthesis simulations in the VCS software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the Settings dialog box, which defaults to the *<project\_directory>/simulation/vcs* directory.

### *Generating Different Timing Model*

If you enable the Quartus II Classic or Quartus II TimeQuest Timing Analyzer when generating the SDO file, slow-corner (worst case) timing models are used by default. To generate the SDO file using a different timing model, you must run the Quartus II Classic or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist writer.

To run the Classic Timing Analyzer with the best-case model, on the Processing menu, point to Start and click **Start Classic Timing Analyzer (Fast Timing Model)**. After timing analysis is complete, the Compilation Report appears. You can also type the following command at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the `-fast_model` option after you create the timing netlist. The following command enables the fast timing models:

```
create_timing_netlist -fast_model
```

You can also type the following command at a command prompt:

```
quartus_sta <project_name> --fast_model=on ↵
```

For more information about generating the timing model, refer to the *Quartus II Classic Timing Analyzer* or *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

After you run the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer, you can perform steps 2 through 8 in “[Generating a Gate-Level Timing Simulation Netlist](#)” on page 3–8 to generate the SDO file. For fast corner timing models, the `_fast` post fix is added to the VO, VHO, and SDO file (for example, `my_project_fast.vo`, `my_project_fast.vho`, and `my_project_fast.sdo`).

### Operating Condition Example: Generate All Timing Models for Stratix III Devices

In Stratix III and Cyclone III devices, you can specify different temperature and voltage parameters to generate the timing models.

Table 3-4 shows the available operation conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Device Family	Model	Voltage	Temperature
Stratix III	Slow	1100 mV	85° C
	Slow	1100 mV	0° C
	Fast	1100 mV	0° C
Cyclone III	Slow	1200 mV	85° C
	Slow	1200 mV	0° C
	Fast	1200 mV	0° C

To generating the SDO files for the three different operating conditions for a Stratix III design, perform the following steps:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ␣
```

2. Generate the ModelSim simulation output files for all three corners specified above. The output files are generated in the simulation output directory. Type the following command at a command prompt:

```
quartus_eda <project name> --simulation --tool=vcs --format=verilog ␣
```

To summarize, for the three operating conditions the steps above generate the following files in the simulation output directory:

First slow corner (slow, 1100 mV, 85° C):

VO file— <revision name>.vo

SDO file— <revision name>\_v.sdo

Second slow corner (slow, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_slow.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_slow.sdo*

Fast corner (fast, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_fast.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_fast.sdo*

## Perform Timing Simulation Using Post-Synthesis Netlist

You can perform a timing simulation using the post-synthesis netlist instead of using a gate-level netlist and you can generate a SDO without running the fitter. In this case, the SDO file includes all timing values for the device cells only. Interconnect delays are not included because fitting (placement and routing) has not been performed.

To generate the post-synthesis netlist and the SDO file, type the following command at a command prompt:

```
quartus_map <project name> -c <revision name> ␣
quartus_tan <project name> -c <revision name> --post_map --zero_ic_delays ␣
quartus_eda <project name> -c <revision name> --simulation --tool=<third party EDA tool>
--format=<HDL language> ␣
```

For more information about the `-format` and `-tool` option, type the following command: `quartus_eda -help=<options> command`

## Common VCS Software Compiler Options

The VCS software has options that help you simulate your design.

[Table 3-5](#) lists some of the options that are available.

Library	Description
-R	Runs the executable file immediately.
-RI	Once the compile has completed, instructs the VCS software to automatically launch VirSim.
-v <library filename>	Specifies a Verilog HDL library file (for example, <b>220model.v</b> or <b>altera_mf.v</b> ). The VCS software looks in this file for module definitions that are found in the source code. Only the relevant library files are compiled based on the modules found.
-y <library directory>	Specifies a Verilog HDL library directory. The VCS software looks for library files in this folder that contain module definitions that are instantiated in the source code.

**Table 3–5. VCS Software Compiler Options (Part 2 of 2)**

Library	Description
+compsdf	Indicates that the VCS software compiler includes the back-annotated SDF file in the compilation.
+cli	The VCS software enters Command-Line Interface (CLI) mode upon successful compilation completion.
+race	Specifies that the VCS software generate a report that indicates all of the race conditions in the design. Default report name is <b>race.out</b> .
-P	Compiles user-defined Programming Language Interface (PLI) table files.
-q	Indicates the VCS software runs in quiet mode. All messages are suppressed.

For more information about any VCS software option, refer to the *VCS User Guide*.

## Using VirSim

VirSim is the graphical debugging system for the VCS software. This tool is included with the VCS software and can be run by using the `-RI` compile-time compiler option when compiling a design. The following VCS software command describes the command-line syntax for compiling and loading a timing simulation in VirSim:

```
vcs -RI <test bench>.v <design name>.vo -v <path to Quartus II installation> \
\eda\sim_lib\<device family>_atoms.v +compsdf ←
```

For more information about using VirSim, refer to the *VirSim User Manual* included in the VCS software installation.

## Debugging Support Command-Line Interface

The VCS software has an interactive non-graphical debugging capability that is very similar to other UNIX debuggers such as the GNU debugger (GDB). The VCS software CLI can be used to halt simulations at user-defined break points, force registers with values, and display values of registers.

Enable the non-graphical capability by using the `+cli` run-time option. Use the VCS software CLI to debug your Altera FPGA design by typing the following command:

```
vcs -R <test bench>.v <design name>.vo
-v <path to Quartus II installation> \
\eda\sim_lib\<device family>_atoms.v +compsdf +cli ←
```

The `+cli` command takes an optional number argument that specifies the level of debugging capability. As the optional debugging capability is increased, the overhead incurred by the simulation is increased, resulting in an increase in simulation times.

For more information about the `+cli` options, refer to the *VCS User Guide* included in the VCS software installation.

For the design examples to run gate-level timing simulation in VHDL or Verilog language, refer to [www.altera.com/support/examples/vcs/exm-vcs.html](http://www.altera.com/support/examples/vcs/exm-vcs.html).

## Simulating Designs that Include Transceivers

If your design includes a Stratix GX or Stratix II GX transceiver, you must compile additional library files to perform functional or timing simulations.

### Stratix GX Functional Simulation

To perform a functional simulation of your design that instantiates the `altgxb` megafunction, enabling the gigabit transceiver block gigabit transceiver block on Stratix GX devices, compile the `stratixgx_mf` model file into the `altgxb` library.

The `stratixiigx_mf` model file references the `lpm` and `sgate` libraries, so you must create these libraries to perform a simulation.

#### *Example of Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL*

To compile the libraries necessary for functional simulation of a Verilog HDL design targeting a Stratix GX device, type the following commands at the VCS command prompt:

```
vcs -R <test bench>.v <design files>.v -v stratixgx_mf.v -v \
sgate.v -v 220model.v -v altera_mf.v ↵
```

### Stratix GX Post-Fit (Timing) Simulation

Perform a post-fit timing simulation of your design that includes a Stratix GX transceiver by compiling the `stratixgx_atoms` and `stratixgx_hssi_atoms` model files into the `stratixgx` and `stratixgx_gxb` libraries, respectively.

The `stratixgx_hssi_atoms` model file references the `lpm` and `sgate` libraries, so you must create these libraries to perform a simulation.

### *Example of Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL*

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix GX device, type the following commands at the VCS command prompt:

```
vcs -R <testbench>.v <gate-level netlist>.vo -v stratixgx_atoms.v -v \  
stratixgx_hssi_atoms.v -v sgate.v -v 220model.v -v altera_mf.v \  
+transport_int_delays +pulse_int_e/0 +pulse_int_r/0 \  
+transport_path_delays +pulse_e/0 +pulse_r/0 ↵
```

## Stratix II GX Functional Simulation

To perform a functional simulation of your design that instantiates the `alt2gxb` megafunction, enabling the gigabit transceiver block gigabit transceiver block on Stratix II GX devices, compile the `stratixiigx_hssi` model file into the `stratixiigx_hssi` library.

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries, so you must create these libraries to perform a simulation.

Generate a functional simulation netlist by turning on **Generate Simulation Model in the Simulation Library** in the `alt2gxb` MegaWizard Plug-In Manager (Figure 3-2). The `<alt2gxb entity name>.vho` file or `<alt2gxb module name>.vo` file is generated in the current project directory.

The Quartus II-generated `alt2gxb` functional simulation library file references `stratixiigx_hssi` wysiwyg atoms.

## Stratix II GX Post-Fit (Timing) Simulation

To perform a post-fit timing simulation of your design that includes a Stratix II GX transceiver, compile `stratixiigx_atoms` and `stratixiigx_hssi_atoms` into the `stratixiigx` and `stratixiigx_hssi` libraries, respectively.

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries, so you must create these libraries to perform a simulation.

### *Example of Compiling Library Files for Timing Stratix II GX Simulation in Verilog HDL*

To compile the libraries necessary for timing simulation of a Verilog HDL design targeting a Stratix II GX device, type the following commands at the VCS command prompt:

```
vcs -R <testbench>.v <gate-level netlist>.vo -v stratixiigx_atoms.v -v \
stratixiigx_hssi_atoms.v -v sgate.v -v 220model.v -v altera_mf.v \
+transport_int_delays +pulse_int_e/0 +pulse_int_r/0 \
+transport_path_delays +pulse_e/0 +pulse_r/0 ←
```

## Using PLI Routines with the VCS Software

The VCS software can interface your custom-defined C code with Verilog HDL source code. This interface is known as PLI. This interface is extremely useful because it allows advanced users to define their own system tasks that currently may not exist in the Verilog HDL.

### Preparing and Linking C Programs to Verilog HDL Code

When compiling the source code, the C code must include a reference to the `vcuser.h` file. This file defines PLI constants, data structures, and routines that are necessary for the PLI interface. This file is included with the VCS software installation and can be found in the `$VCS_HOME\lib` directory.

Once the C code is complete, you must create an object file (`.o`). Create the object file with the following command:

```
gcc -c my_custom_function.c ←
```

Next, you must create a PLI table file (`.tab`). This file maps the C program task to the matching task `$task` in the Verilog HDL source code. You can create this file using a standard text editor. The following is an example of an entry in the PLI file:

```
$my_custom_function call=my_custom_function acc+=rw* ←
```

The Verilog HDL code can now include a reference to the user-defined task. To compile an Altera FPGA design that includes a reference to a user-defined system task, type the following at the command-line prompt:

```
vcs -R <test bench>.v <design name>.v -v <Altera library file>.v -P <my_tabfile.tab> \
<my_custom_function.o> ↵
```

## Transport Delays

By default, the VCS software filters out all pulses that are shorter than the propagation delay between primitives. Turning on the transport delay options in the VCS software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

### *+transport\_path\_delays*

Use this option when the pulses in your simulation may be shorter than the delay within a gate-level primitive. For this option to work you must also include the *+pulse\_e/number* and *+pulse\_r/number* options.

### *+transport\_int\_delays*

Use this option when the pulses in your simulation may be shorter than the interconnect delay between gate-level primitives. For this option to work, you must also include the *+pulse\_int\_e/number* and *+pulse\_int\_r/number* options. The *+transport\_path\_delays* and *+transport\_int\_delays* options are also used by default in the NativeLink feature for gate-level timing simulation.

For more information about either of these options, refer to the *VCS User Guide* installed with the VCS software.

The following VCS software command describes the command-line syntax to perform a post-synthesis simulation with the device family library:

```
vcs -R <test bench>.v <gate-level netlist>.v -v <altera device family library>.v \
+transport_int_delays +pulse_int_e/0 +pulse_int_r/0 \
+transport_path_delays +pulse_e/0 +pulse_r/0 ↵
```

## Using NativeLink with the VCS Software

The NativeLink® feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run VCS within the Quartus II software.

### Setting Up NativeLink

To run VCS automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**. The **EDA Tool Options** page is shown.
3. Double-click the entry under the **Location of executable** column.
4. Type or browse to the directory containing the executables of your EDA tool.
5. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` Tcl command:

```
set_user_option -name EDA_TOOL_PATH_VCS <path to executables> ↵
```

### Performing an RTL Simulation Using NativeLink

To run a functional RTL simulation automatically with the VCS software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page is shown (Figure 3-3).

Figure 3–3. Simulation Page in the Settings Dialog Box

3. In the **Tool name** list, select **VCS**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
4. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

For more information about setting up a testbench with NativeLink, refer to [“Setting Up a Testbench” on page 3–21](#).

5. Click **OK**.

6. On the Processing menu, point to Start and click **Start Analysis and Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
7. On the Tools menu, point to **EDA Simulation Tool** and click **Run EDA RTL Simulation** to automatically launch VCS, compile all necessary design files, and complete a simulation.

### Performing a Gate-Level Simulation Using NativeLink

To run a gate-level timing simulation with the VCS software automatically in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page is shown (Figure 3-3).
3. In the **Tool name** list, select **VCS**.
4. You can modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To perform a gate level simulation after each full compilation, turn on **Run Gate Level Simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. Click **OK**.
8. Perform a full compilation. On the Processing menu, click **Start Compilation**.
9. On the Processing menu, point to Start and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.
10. On the Tools menu, point to EDA Simulation Tool and click **Run EDA Gate Level Simulation** to automatically launch VCS, compile all necessary design files, and complete a simulation.

A VCS file (\*.vcs) is generated in the `<project_directory>\simulation\vcs` directory while running the NativeLink. With this VCS File (\*.vcs), you can simulate the design using the following command without using the NativeLink:

```
vcs -file <project_directory>\simulation\vcs\<generated_do_file>.vcs
```

## Setting Up a Testbench

You can automatically launch your EDA simulator tool, compile your design files and testbench files, and perform a simulation automatically using the NativeLink feature.

To setup NativeLink with a testbench, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, click the “+” icon to expand **EDA Tool Settings** and select **Simulation**. The **Simulation** page is shown.
3. Under **NativeLink settings**, select **None** or **Compile test bench** (Table 3–6).

<b>Settings</b>	<b>Description</b>
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile test bench** list. You can use different testbench setups to specify different testbench files for different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:
  - a. Click **Test Benches**. The **Test Benches** dialog box appears.
  - b. Click **New**. The **New Test Bench Settings** dialog box appears.
  - c. In the **Test Bench name** box, type in the testbench setup name which is used to identify between the different testbench setups.

- d. In the **Test bench entity** box, type in the top-level entity name. For example, for a Quartus II generated Verilog testbench, type in *<Vector Waveform File name>\_vlg\_vec\_tst*.
- e. In the **Instance** box, type the full instance path to the top level of your FPGA design. For example, for a Quartus II generated Verilog test bench, type *i1*.
- f. Under **Simulation period**, select **Run simulation until all vector stimuli are used**. If you select **End simulation at**, specify the simulation end time and the time unit.
- g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** buttons to reorder your files. The script used by NativeLink compiles the files in the order from top to the bottom.

You can also specify the library name and the HDL version to compile the testbench file. NativeLink compiles the testbench to the library name of the HDL specified version.

- h. Click **OK**.
- i. In the **Test Benches** dialog box, click **OK**.

### *Creating a Testbench*

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File. The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your file.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box appears.
5. Click the **Save as type** arrow and select **VHDL Test Bench File (\*.vht)** or **Verilog Test Bench File (\*.vt)**.
6. You can turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.

## Scripting Support

### 7. Click **Export**.

You can run procedures and create settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command-line scripting, refer to the *Command Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For detailed information about scripting command options, refer to the **Qhelp** utility.

To start the **Qhelp** utility, type this command:

```
quartus_sh --qhelp ←
```

### Generating a Post-Synthesis Simulation Netlist for VCS

You can use the Quartus II software to generate a post-synthesis simulation netlist with Tcl commands or with a command at a command prompt.

#### *Tcl Commands*

Use the following Tcl commands:

```
set_global_assignment -name EDA_SIMULATION_TOOL "VCS" ←
set_global_assignment -name EDA_GENERATE_FUNCTIONAL_NETLIST ON ←
```

#### *Command Prompt*

Use the following command to generate a simulation output file for the VCS software simulator; specify VHDL or Verilog HDL for the format:

```
quartus_eda <project name> --simulation=on --format=<format> --tool=vcs
--functional ←
```

### Generating a Gate-Level Timing Simulation Netlist for VCS

You can use the Quartus II software to generate a gate-level timing simulation netlist with Tcl commands or with a command at a command prompt.

### *Tcl Commands*

Use the following Tcl commands:

```
set_global_assignment -name EDA_SIMULATION_TOOL "VCS" ←
```

### *Command Prompt*

Use the following command to generate a simulation output file for the VCS software simulator. Specify VHDL or Verilog HDL for the format.

```
quartus_eda <project name> --simulation=on --format=<format> --tool=vcs ←
```

## **Conclusion**

You can use the VCS software in your Altera FPGA design flow to easily and accurately perform functional RTL simulations, post-synthesis simulations, and gate-level functional timing simulations. The seamless integration of the Quartus II software and VCS software make this simulation flow an ideal method for fully verifying an FPGA design.

### Introduction

This chapter is a getting started guide to using the Cadence Incisive verification platform software in Altera® FPGA design flows. The Incisive verification platform software includes NC-Sim, NC-Verilog, NC-VHDL, Verilog, and VHDL desktop simulators. This chapter provides step-by-step explanations of the basic NC-Sim, NC-Verilog, and NC-VHDL functional, post-synthesis, and gate-level timing simulations. It also describes the location of the simulation libraries and how to automate simulations.

This chapter contains the following topics:

- [“Software Requirements”](#)
- [“Functional and RTL Simulation”](#) on page 4–6
- [“Post-Synthesis Simulation”](#) on page 4–22
- [“Gate-Level Timing Simulation”](#) on page 4–24
- [“Simulating Designs that Include Transceivers”](#) on page 4–31
- [“Using the NativeLink Feature with NC-Sim”](#) on page 4–37
- [“Incorporating PLI Routines”](#) on page 4–43
- [“Scripting Support”](#) on page 4–48

### Software Requirements

You must first install the Quartus® II software before using it with the Cadence Incisive verification platform software. The Cadence interface is installed automatically when you install the Quartus II software on your computer.

Table 4-1 shows the Cadence NC simulator versions compatible with specific Quartus II software versions.

**Table 4-1. Compatibility Between Software Versions**

<b>Quartus II Software</b>	<b>Cadence NC Simulators (UNIX)</b>	<b>Cadence NC Simulators (PC)</b>	<b>Cadence NC Simulators (Linux)</b>

## Simulation Flow Overview

The Incisive platform software supports the following simulation flows:

- Functional and RTL Simulation
- Post-Synthesis Simulation
- Gate-Level Timing Simulation
- Using the NativeLink Feature with NC-Sim

Figure 4-1 shows the Quartus II software and Cadence design flow.

**Figure 4-1. Quartus II Software Design Flow with Cadence NC Simulators**

Functional and RTL simulation verifies the functionality of your design. When you perform a functional simulation with Cadence Incisive simulators, you use your design files (Verilog HDL or VHDL) and the models provided with the Quartus II software. These Quartus II models are required if your design uses the library of parameterized modules (LPM) functions or Altera-specific megafunctions. Refer to [“Functional and RTL Simulation” on page 4–6](#) for more information about how to perform this simulation.

A post-synthesis simulation verifies the functionality of a design after synthesis has been performed. You can create a post-synthesis netlist (`.vo` or `.vho`) in the Quartus II software and use this netlist to perform a post-synthesis simulation with the Incisive simulator. Refer to [“Post-Synthesis Simulation” on page 4–22](#) for more information about how to perform this simulation.

After performing place-and-route, the Quartus II software generates a Verilog Output File (`.vo`) or VHDL Output File (`.vho`) and a Standard Delay Output file (`.sdo`) for gate-level timing simulation. The netlist files map your design to architecture-specific primitives. The SDO file contains the delay information of each architecture primitive and routing element specific to your design. Together, these files provide an accurate simulation of your design with the selected Altera FPGA architecture. Refer to [“Gate-Level Timing Simulation” on page 4–24](#) for more information about how to perform this simulation.

## Operation Modes

In the NC simulators, you can use either the GUI mode or the command-line mode to simulate your design.

You can start the Incisive simulators in GUI mode in a PC or a UNIX environment by typing `ncLaunch` at a command prompt.

To simulate in command-line mode, use the programs shown in [Table 4-2](#).

<b>Program</b>	<b>Function</b>
<b>ncvlog</b> or <b>ncvhdl</b>	NC-Verilog ( <b>ncvlog</b> ) compiles your Verilog HDL code into a Verilog Syntax Tree (.vst) file. <b>ncvlog</b> also performs syntax and static semantics checks.  NC-VHDL ( <b>ncvhdl</b> ) compiles your VHDL code into a VHDL Syntax Tree (.ast) file. <b>ncvhdl</b> also performs syntax and static semantics checks.
<b>ncelab</b>	NC-Elab ( <b>ncelab</b> ) elaborates the design. <b>ncelab</b> constructs the design hierarchy and establishes signal connectivity. This program also generates a Signature File (.sig) and a Simulation SnapShot File (.sss).
<b>ncsim</b>	NC-Sim ( <b>ncsim</b> ) performs mixed-language simulation. This program is the simulation kernel that performs event scheduling and executes the simulation code.

## Quartus II Software and NC Simulation Flow Overview

An overview of the Quartus II software and Cadence NC simulation flow is described below. More detailed information is provided in [“Functional and RTL Simulation” on page 4-6](#), [“Post-Synthesis Simulation” on page 4-22](#), and [“Gate-Level Timing Simulation” on page 4-24](#).

1. Set up your working environment (UNIX only).

You must set several environment variables in UNIX to establish an environment that facilitates entering and processing designs.

2. Create user libraries.

Create a file that maps logical library names to their physical locations. These library mappings include your working directory and any design-specific libraries; for example, Altera LPM functions or megafunctions.

3. Compile source code and testbenches.

You compile your design files at the command-line using **ncvlog** (Verilog HDL files) or **ncvhdl** (VHDL files), or on the Tools menu by clicking **Verilog Compiler** or **VHDL Compiler** in NCLaunch. During compilation, the NC software performs syntax and static semantic checks. If no errors are found, compilation produces an

internal representation for each HDL design unit in the source files. By default, these intermediate objects are stored in a single, packed, library database file in your working directory.

4. Elaborate your design.

Before you can simulate your model, you must define the design hierarchy in a process called elaboration. Use **ncelab** in command-line mode or on the Tools menu, click **Elaborator** in NCLaunch to elaborate the design.

5. Add signals to your waveform.

Before simulating, specify which signals to view in your waveform using a simulation history manager (SHM) database.

6. Simulate your design.

Run the simulator with the **ncsim** program (command-line mode) or by clicking **Run** in the SimVision Console window.

## Functional and RTL Simulation

The following sections provide detailed instructions for performing functional/RTL simulation using the Quartus II software and the Cadence Incisive platform software tools.

### Create Libraries

Before simulating with the Incisive simulator, you must set up libraries with a file named **cds.lib**. The **cds.lib** file is an ASCII text file that maps logical library names—for example, your working directory or the location of resource libraries such as models for LPM functions—to their physical directory paths. When you run the Incisive simulator, the tool reads **cds.lib** to determine which libraries are accessible and where they are located. There is also a default **cds.lib** file, which you can modify for your project settings.

You can use more than one **cds.lib** file. For example, you can have a project-wide **cds.lib** file that contains library settings specific to a project such as technology or cell libraries and a user **cds.lib** file.

The following sections describe how to create and edit a **cds.lib** file:

- Basic libraries setup
- LPM function, Altera megafunction, and Altera primitive library setup

### Basic Library Setup

You can create a **cds.lib** file with any text editor. The following examples show how you use the `DEFINE` statement to bind a library name to its physical location. The logical and physical names can be the same or you can select different names. The `DEFINE` statement usage is:

```
DEFINE <library name> <physical directory path>
```

For example, a simple **cds.lib** file for Verilog HDL contains the following lines:

```
DEFINE lib_std /usr1/libs/std_lib
DEFINE worklib ../worklib
```

### Using Multiple cds.lib Files

Use the `INCLUDE` or `SOFTINCLUDE` statement to reference another **cds.lib** file within a **cds.lib** file. The syntax is:

```
INCLUDE <path to another cds.lib>
```

or

```
SOFTINCLUDE <path to another cds.lib>
```

For the Windows operating system, enclose the path with quotation marks if there are spaces in the directory path.

For VHDL or mixed-language simulation, in addition to the `DEFINE` statements, you must include the default **cds.lib** file (included with NC-Sim). The syntax for including the default **cds.lib** file is:

```
INCLUDE <path to NC installation>/tools/inca/files/cds.lib
```

or

```
INCLUDE $CDS_INST_DIR/tools/inca/files/cds.lib
```

The default **cds.lib** file, provided with NC tools, contains a `SOFTINCLUDE` statement to include other **cds.lib** files, such as **cdsvhdl.lib** and **cdsvlog.lib**. These files contain library definitions for IEEE libraries and Synopsys libraries.

### Create a cds.lib File in Command-Line Mode

To create a **cds.lib** file at a the command prompt, perform the following steps:

1. Create a directory for the work library and any other libraries you need by typing the following command at a command prompt:

```
mkdir <library name> ↵
```

For example: `mkdir worklib ↵`

2. Using a text editor, create a **cds.lib** file and add the following line to it:

```
DEFINE <library name> <physical directory path>
```

For example: `DEFINE worklib ./worklib`

### Create a cds.lib File in GUI Mode

To create a **cds.lib** file using the GUI, perform the following steps:

1. Type `nclaunch ↵` at the command line to run the GUI.
2. If the NCLaunch window is not in multiple step mode, on the File menu, click **Switch to Multiple Step**.
3. Change your design directory on the File menu by clicking **Set Design Directory**. The **Set Design Directory** dialog box appears (Figure 4–2).

**Figure 4–2. Creating a Work Directory in GUI Mode**

4. Click **Browse** to navigate to your design directory.
5. Click **Create cds.lib File** and in the **New cds.lib File** dialog box, click **Save** and choose the libraries you want to include.
6. Click **New** under **Work Library**.
7. Enter your new work library name, for example, `worklib`.
8. Click **OK**. The new library is displayed under **Work Library**. [Figure 4-2](#) shows an example using the directory name `worklib`.
9. Repeat steps 7 and 8 for each functional simulation library. For example, `lpm`, `altera_mf`, and `altera`.
10. Click **OK** in the **Set Design Directory** dialog box.

You can edit your libraries by editing the `cds.lib` file. Edit the `cds.lib` file by right-clicking the `cds.lib` filename in the right side of the window and choosing **Edit**.

### *LPM Functions, Altera Megafunctions, and Altera Primitives Libraries*

Altera provides behavioral descriptions for LPM functions, Altera-specific megafunctions, and Altera primitives. You can implement the megafunctions in a design using the Quartus II MegaWizard® Plug-In Manager or by instantiating them directly from your design file. You must set up resource libraries so that you can simulate your design in the Incisive simulator if your design uses LPM functions, Altera megafunctions, or Altera primitives.

Many LPM functions and Altera megafunctions use memory files. You must convert the memory files into a format the Incisive tools can read before simulating. Follow the instructions in [“Compile Source Code and Testbenches”](#) on page 4-13 to connect the memory files.

Altera provides megafunction behavioral descriptions in the files shown in [Table 4-3](#). These library files are located in the following directory:

`<path to Quartus II installation>/eda/sim_lib` directory.

For more information about LPM functions and Altera megafunctions, refer to the Quartus II Help.

**Table 4–3. Megafunction Behavioral Description Files**

Library Description	Verilog HDL	VHDL
LPM	<b>220model.v</b>	<b>220model.vhd</b> (1) <b>220model_87.vhd</b> (2) <b>220pack.vhd</b>
Altera megafunction	<b>altera_mf.v</b>	<b>altera_mf.vhd</b> (1) <b>altera_mf_87.vhd</b> (2) <b>altera_components.vhd</b>
Altera primitives	<b>altera_primitives.v</b>	<b>altera_primitives.vhd</b> (1) <b>altera_primitives_components.vhd</b>
IP functional simulation model	<b>sgate.v</b>	<b>sgate.vhd</b> <b>sgate_pack.vhd</b>
altgxb	<b>stratixgx_mf.v</b> (3)	<b>stratixgx_mf.vhd</b> (3) <b>stratixgx_mf_components.vhd</b> (3)
alt2gxb	<b>stratixiigx_hssi_atoms.v</b> , <b>arriagx_hssi_atoms.v</b> (3), (4)	<b>stratixiigx_hssi_atoms.vhd</b> <b>stratixiigx_hssi_components.vhd</b> <b>arriagx_hssi_atoms.vhd</b> <b>arriagx_hssi_components.vhd</b> (3), (4)

**Notes to Table 4–3:**

- (1) Use this model with VHDL 93.
- (2) Use this model with VHDL 87.
- (3) The alt2gxb and altgxb library files require the **lpm** and **sgate** libraries.
- (4) You must generate a functional simulation netlist for simulation.

If an **lpm** library does not exist, set up a library for LPM functions by creating a new directory and adding the following line to your **cds.lib** file:

```
DEFINE lpm <path>/<directory name>
```

If an **altera\_mf** library does not exist, set up a library for Altera megafunctions by adding the following line to your **cds.lib** file:

```
DEFINE altera_mf <path>/<directory name>
```

### Megafunctions Requiring Atom Libraries

The following Altera megafunctions require device atom libraries to perform a functional simulation in a third-party simulator:

- altclkbuf
- altclkctrl
- altdq
- altdqs
- altddio\_in
- altddio\_out
- altddio\_bidir
- altufm\_none
- altufm\_parallel
- altufm\_spi
- altmemmult
- altremote\_update

The device atom library files are located in the following directory:

`<path to Quartus II installation>/eda/sim_lib`

### Simulating a Design with Memory

The NC-Sim simulator supports simulating Altera memory megafunctions initialized with Hexadecimal (Intel-Format) File (.hex) or RAM Initialization Files (.rif).

Although synthesis is able to read a Memory Initialization File (.mif), these files are not supported in simulations with third-party tools and must be converted to either a Hexadecimal (Intel-Format) File or RAM Initialization File.

Table 4-4 summarizes the different types of memory initialization file formats that are supported with each RTL language.

File	Verilog HDL	VHDL
Hexadecimal (Intel-Format) File	Yes (1)	Yes
Memory Initialization File	No	No
RAM Initialization File	Yes (2)	No

**Notes to Table 4-4:**

- (1) For memories and library files from Quartus II software version 5.0 and earlier, you are required to use a PLI library containing the `convert_hex2ver` task function.
- (2) Requires the `USE_RIF` macro to be defined.

To convert your Memory Initialization File into either a Hexadecimal (Intel-Format) File or RAM Initialization File, perform the following steps:

1. Open the Memory Initialization File and on the File menu, click **Export**. The **Export** dialog box appears.
2. Select **Hexadecimal (Intel-Format) File (\*.hex)** or **RAM Initialization File (\*.rif)** from the **Save as type** list and click **OK**.

Alternatively, you can convert a Memory Initialization File to a RAM Initialization File using the `mif2rif.exe` executable located in the `<Quartus II installation>/bin` directory. An example of this executable is:

```
mif2rif <mif_file> <rif_file>
```

3. Modify the HDL file generated with the MegaWizard Plug-In Manager.

The MegaWizard Plug-In Manager-generated Altera memory megafunction wrapper file includes the `lpm_file` parameter for LPM memories, or the `init_file` parameter for Altera-specific memories to point to the initialization file.

In a text editor, open the MegaWizard Plug-In Manager generated wrapper file and edit the `lpm_file` or `init_file` parameters to point to the Hexadecimal (Intel-Format) File or RAM Initialization File, as shown below:

```
lpm_ram_dp_component.lpm_file = "<path to HEX/RIF>"
```

4. Compile the functional library files with compiler directives.

If you use a Hexadecimal (Intel-Format) File, no compiler directives are required. If you use a RAM Initialization File, the `USE_RIF` macro must be defined when compiling the model library files. For example, the following should be entered when compiling the `altera_mf` library when RAM Initialization Files are used:

```
nvclog -work altera_mf altera_mf.v -DEFINE  
"USE_RIF=1"
```

For Quartus II software versions 5.0 and earlier, you must define the `NO_PLI` macro instead of `USE_RIF`. The `NO_PLI` macro is forward compatible with the Quartus II software.

## Compile Source Code and Testbenches

Compile your testbench and design files with **ncvlog** (for Verilog HDL files) and **ncvhdl** (for VHDL files). Both **ncvlog** and **ncvhdl** perform syntax checks and static semantic checks. A successful compilation produces an internal representation for each HDL design unit in the source files. By default, these intermediate objects are stored in a single, packed, library database file in your work library directory.

### Compilation in Command-Line Mode

To compile from the command line, use one of the following commands:

You must create a work library before compiling.

#### ■ Verilog HDL:

```
ncvlog <options> -work <library name> <design files> ↵
```

#### ■ VHDL:

```
ncvhdl <options> -work <library name> <design files> ↵
```

If your design uses LPM, Altera megafunctions, or Altera primitives, you must also compile the Altera-provided functional models. The following commands show an example of each.

#### ■ Verilog HDL:

```
ncvlog -WORK lpm 220model.v ↵
ncvlog -WORK altera_mf altera_mf.v ↵
ncvlog -WORK altera altera_primitives.v ↵
```

If you are using the Quartus II software versions 5.0 and earlier and your design uses a memory initialization file, compile the **nopli.v** file, which is located in the *<Quartus II installation>/eda/sim\_lib* directory, before you compile your model. For example:

```
ncvlog -WORK lpm nopli.v 220model.v ↵
ncvlog -WORK altera_mf nopli.v altera_mf.v ↵
```

Another option is to define **NO\_PLI** during compilation with the following command:

```
ncvlog -DEFINE "NO_PLI=1" -WORK lpm 220model.v ↵
ncvlog -DEFINE "NO_PLI=1" -WORK altera_mf altera_mf.v ↵
```

#### ■ VHDL:

```
ncvhdl -V93 -WORK lpm 220pack.vhd ↵
ncvhdl -V93 -WORK lpm 220model.vhd ↵
ncvhdl -V93 -WORK altera_mf altera_mf_components.vhd ↵
ncvhdl -V93 -WORK altera_mf altera_mf.vhd ↵
ncvhdl -V93 -WORK altera altera_primitives_components.vhd ↵
```

```
ncvhdl -V93 -WORK altera altera_primitives.vhd ↵
```

### Compilation in GUI Mode

To compile using the NCLaunch GUI, perform the following steps:

1. Right-click a library filename in the NCLaunch window and click **NCVlog** (Verilog HDL) or **NCVhdl** (VHDL).

Alternatively, on the Tools menu, click **Verilog Compiler** or **VHDL Compiler**. Figure 4-3 shows the **Compile Verilog** and **Compile VHDL** dialog boxes.

Figure 4-3. Compiling Verilog HDL and VHDL Files

2. Select the file and click **OK** in the **Compile Verilog** or **Compile VHDL** dialog box to begin compilation. The dialog box closes and returns you to NCLaunch.

The command-line equivalent argument is shown at the bottom of the NCLaunch window.

## Elaborate Your Design

Before you can simulate your design, you must define the design hierarchy in a process called elaboration. When you use the Incisive simulator, you use the language-independent **ncelab** program to elaborate your design. The **ncelab** program constructs a design hierarchy based on the design's instantiation and configuration information, establishes signal connectivity, and computes initial values for all objects in the design. The elaborated design hierarchy is stored in a simulation snapshot, which is the representation of your design that the simulator uses to run the simulation. The snapshot is stored in the library database file, along with the other intermediate objects generated by the compiler and elaborator.

If you are running the NC-Verilog simulator with the single-step invocation method (**ncverilog**), and want to compile your source files and elaborate the design with one command, use the `+elaborate` option to stop the simulator after elaboration, for example:

```
ncverilog +elaborate test.v ↵
```

### *Elaboration in Command-Line Mode*

To elaborate your Verilog HDL or VHDL design from the command line, use the following command:

```
ncelab [options] [<library>.] <cell> [:<view>] ↵
```

You can set your simulation timescale using the `-TIMESCALE <arguments>` option. The following example elaborates a dual-port RAM with the time scale option:

```
ncelab -TIMESCALE 1ps/1ps worklib.lpm_ram_dp_test:entity ↵
```

If you specified a timescale of 1 ps in the Verilog HDL testbench, the `TIMESCALE` option is not necessary. Using a ps resolution ensures the correct simulation of your design.

If your design includes high speed signals, you may need to add the following pulse reject options with your `ncelab` command.

```
ncelab -TIMESCALE 1ps/1ps worklib.mydesign:entity -PULSE_R 0 -PULSE_INT_R 0 ↵
```

For more information about the pulse reject options, refer to the *SDF Annotate Guide* from Cadence.

To list the elements in your library and the available views, use the **ncls** program. The following command displays all of the cells and their views in your current **worklib** directory:

```
ncls -library worklib ←
```

For more information about the **ncls** program, refer to the Cadence NC-Verilog Simulator Help or Cadence NC-VHDL Simulator Help.

### *Elaboration in GUI Mode*

To elaborate using the GUI, perform the following steps:

1. In the right side of the NCLaunch window, expand your current work library.
2. Select and expand (if necessary) the entity or module name you want to elaborate.
3. Right-click the view you want to display and click **NCElab**. The **Elaborate** dialog box appears (Figure 4-4). Optionally, on the Tools menu, click **Elaborator**.
4. In the **Other Options** box, set the simulation timescale by typing (Figure 4-4):

```
-TIMESCALE 1ps/1ps
```

Figure 4–4. Elaborating the Design

- Click **OK** in the **Elaborate** dialog box to begin elaboration. The dialog box closes and returns you to NCLaunch.

## Add Signals to View

To view the stored selected signals, use an SHM database, which is a Cadence proprietary waveform database, to store the selected signals you want to view. Before you can specify which signals to view, you must create the database by adding commands to your code. Or you can create a Value Change Dump File (**.vcd**) to store the simulation history.

For more information about using a Value Change Dump File, refer to the *Cadence NC-Sim User Manual* from Cadence included with the installation.

### *Adding Signals in Command-Line Mode*

To create an SHM database, specify the system tasks described in [Table 4–5](#) in your Verilog HDL code.

For VHDL, you can use the Tcl command interface or C function calls to add signals to a database. Refer to the Cadence documentation included in the installation package for details.

**Table 4–5. SHM Database System Tasks**

System Task	Description
<code>\$shm_open("&lt;filename&gt;.shm");</code>	Opens a database. If you do not specify a filename, the default <b>waves.shm</b> database opens. If a database with the specified name does not exist, it is created for you.
<code>\$shm_probe("[A S C]");</code>	Probe signals. You can specify the signals to probe; if you do not specify signals, the default is all ports in the current scope.  A probes all nodes in the current scope. S probes all nodes below the current scope. C probes all nodes below the current scope and in libraries.
<code>\$shm_save;</code>	Saves the database.
<code>\$shm_close;</code>	Closes the database.

The following sample shows a simple example of how to add signals to an SHM database.

```
initial
begin
    $shm_open ("waves.shm");
    $shm_probe ("AS");
end
```

You can insert this code sample into your Verilog HDL file. It is applicable only for Verilog HDL files. For more information about these system tasks, refer to the Cadence NC-Sim software user manual included in the installation.

### *Adding Signals in GUI Mode*

To add signals in GUI mode, perform the following steps:

1. In the NC-Sim software, load the design.
  - a. In the NCLaunch window, click the + icon to expand the **Snapshots** directory.
  - b. Right-click on the **lib.cell:view** you want to simulate and click **NCSim**.

- c. Click **OK** in the **Simulate** dialog box.

After you load the design, the SimVision Console and SimVision Design Browser windows appear. Figure 4–5 shows the SimVision Design Browser window.

2. In the Design Browser window, select a module in the left side of the window to display the signal names (Figure 4–5).

**Figure 4–5. SimVision Design Browser**

3. To send the selected signals to the Waveform Viewer, perform one of the following steps:

Select a group of signals from the right side of the Design Browser window and click the **Send to Waveform Viewer** icon in the **Send To** toolbar (the upper-right area of the Design Browser window).

or

Right-click the signals and click **Send to Waveform Window** (Figure 4–6).

A waveform window showing all of your signals appears. You are now ready to simulate your testbench and design.

**Figure 4–6. Selecting Signals in the Design Browser Window**

## Simulate Your Design

After you have compiled and elaborated your design, you can simulate it using `ncsim`. The `ncsim` program loads the file or snapshot generated by `nclab` as its primary input. It then loads other intermediate objects referenced by the snapshot. If you enable interactive debugging, it may also load HDL source files and script files. The simulation output is controlled by the model or debugger. The output can include result files generated by the model, SHM database, or Value Change Dump File.

*Functional/RTL Simulation in Command-Line Mode*

To perform functional/RTL simulation of your Verilog HDL or VHDL design at the command line, type the following command:

```
ncsim [options] [<library>.] <cell>[:<view>] ↵
```

For example:

```
ncsim worklib.lpm_ram_dp:syn ↵
```

Table 4-6 shows some of the options you can use with `ncsim`.

<b>Options</b>	<b>Description</b>
-gui	Launch GUI mode
-batch	Used for non-interactive mode
-tcl	Used for interactive mode (not required when using -gui)

*Functional/RTL Simulation in GUI Mode*

You can run and step through simulation of your Verilog HDL or VHDL design in the GUI. In the Design Browser window, on the Simulation menu, click **Run** to begin the simulation.

You must load the design before simulating. If you have not done so, refer to step 1 in “Adding Signals in GUI Mode” on page 4-18 for instructions.

## Post-Synthesis Simulation

The following sections provide detailed instructions for performing post-synthesis simulation using Quartus II output files, simulation libraries, and the Incisive platform software.

### Quartus II Simulation Output Files

After performing synthesis with either a third-party synthesis tool or with the Quartus II integrated synthesis, you must generate a simulation netlist for functional simulations. To generate a simulation netlist for functional simulation, perform the following steps in the Quartus II software:

1. Perform Analysis and Synthesis. On the Processing menu, point to Start and click **Start Analysis and Synthesis**.
2. Turn on the **Generate Netlist for Functional Simulation Only** option by performing the following steps:
  - a. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
  - b. In the **Category** list, select **Simulation**. The **Simulation** page appears.
  - c. In the **Tool name** list, select **NCSim**.
  - d. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
  - e. Click **More Settings**. The **More EDA Tools Simulation Settings** dialog box appears. In the **Existing options settings list**, click **Generate Netlist for Functional Simulation Only** and select **On** from the **Setting** list under **Option**.
  - f. Click **OK**.
  - g. In the **Settings** dialog box, click **OK**.
3. Run the EDA Netlist Writer. On the Processing menu, point to Start and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (.vo) or VHDL Output File (.vho) that can be used for post-synthesis simulations in the NC-Sim software. This netlist file is mapped to architecture-specific primitives. No timing information is included at this stage. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the `<project directory>/simulation/NCsim` directory.

## Create Libraries

Create the following libraries for your simulation:

- Work library
- Device family library targeting your design targets using the following files in the `<path to Quartus II installation>/eda/sim_lib` directory:
  - `<device_family>_atoms.v`
  - `<device_family>_atoms.vhd`
  - `<device_family>_components.vhd`

## Compile Project Files and Libraries

Compile the project files and libraries into your work directory using the `ncvlog` or `ncvhdl` programs or the GUI. Include the following files:

- Test bench file
- The Quartus II software functional output netlist file (Verilog Output File or VHDL Output File)
- Atom library file for the device family  
`<device family>_atoms.<v | vhd>`
- For VHDL, `<device family>_components.vhd`

Refer to the section [“Compile Source Code and Testbenches” on page 4–13](#) for instructions about compiling.

## Elaborate Your Design

Elaborate your design using the `ncelab` program as described in [“Elaboration in GUI Mode” on page 4–16](#).

## Add Signals to the View

Refer to the section [“Add Signals to View” on page 4–17](#) for information about adding signals to the view.

## Gate-Level Timing Simulation

### Simulate Your Design

Simulate your design using the `ncsim` program as described in “[Simulate Your Design](#)” on page 4–20.

The following sections provide detailed instructions for performing timing simulation using the Quartus II output files, simulation libraries, and Cadence NC tools.

### Generating a Gate-Level Timing Simulation Netlist

To perform gate-level timing simulation, the NC-Sim software requires information about how the design was placed into device-specific architectural blocks. The Quartus II software provides this information in the form of a Verilog Output File for Verilog HDL designs and a VHDL Output File for VHDL designs. The accompanying timing information is stored in the SDO file, which annotates the delay for the elements found in the Verilog Output File or VHDL Output File.

To generate the Verilog Output File or VHDL Output Files and the Standard Delay File, perform the following steps:

1. Perform a full compilation. On the Processing menu, click **Start Compilation**.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, select **Simulation**. The **Simulation** page appears.
4. In the **Tool name** list, select **NCSim**.
5. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
6. Click **OK**.
7. Run the EDA Netlist Writer. On the Processing menu, point to Start and click **Start EDA Netlist Writer**.

During the EDA Netlist Writer stage, the Quartus II software produces a Verilog Output File (`.vo`), VHDL Output File (`.vho`), and a SDO file used for gate-level timing simulations in the NC-Sim software. This netlist file is mapped to architecture-specific

primitives. The timing information for the netlist is included in the SDO file. The resulting netlist is located in the output directory you specified in the **Settings** dialog box, which defaults to the *<project directory>/simulation/ncsim* directory.

### Generating a Different Timing Model

If you enable the Quartus II Classic Timing Analyzer or Quartus II TimeQuest Timing Analyzer when generating the SDO file, slow-corner (worst case) timing models are used by default. To generate the SDO file using a different timing model, you must run the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer with a different timing model before you start the EDA Netlist Writer.

To run the Quartus II Classic Timing Analyzer with the best-case model, on the Processing menu, point to Start and click **Start Classic Timing Analyzer (Fast Timing Model)**. After timing analysis is complete, the Compilation Report appears. You can also type the following at a command prompt:

```
quartus_tan <project_name> --fast_model=on ↵
```

To run the Quartus II TimeQuest Timing Analyzer with a best-case model, use the `-fast_model` option after you create the timing netlist. The following command enables the fast timing models:

```
create_timing_netlist -fast_model
```

You can also type the following command at a command prompt:

```
quartus_sta <project_name> --fast_model=on ↵
```

For more information about generating the timing model, refer to the *Quartus II Classic Timing Analyzer* or *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

After you run the Quartus II Classic Timing Analyzer or Quartus II TimeQuest Timing Analyzer, you can perform steps 2 through 7 in “[Generating a Gate-Level Timing Simulation Netlist](#)” on page 4–24 to generate the SDO file. For fast corner timing models, the `_fast` post fix is added to the VO, VHO, and SDO file (for example, `my_project_fast.vo`, `my_project_fast.vho`, and `my_project_fast.sdo`).

### Operating Condition Example: Generate All Timing Models for Stratix III and Cyclone III Devices

In Stratix® III and Cyclone® III devices, you can specify different temperature and voltage parameters to generate the timing models.

Table 4-7 shows the available operating conditions (model, voltage, and temperature) for Stratix III and Cyclone III devices.

Device Family	Model	Voltage	Temperature
Stratix III	Slow	1100 mV	85° C
	Slow	1100 mV	0° C
	Fast	1100 mV	0° C
Cyclone III	Slow	1200 mV	85° C
	Slow	1200 mV	0° C
	Fast	1200 mV	0° C

To generate the SDO files for the three different operating conditions for a Stratix III design, perform the following steps:

1. Generate all the available corner models at all operating conditions. Type the following command at a command prompt:

```
quartus_sta <project name> --multicorner ↵
```

2. Generate the ModelSim simulation output files for all three corners specified above. The output files are generated in the simulation output directory. Type the following command at a command prompt:

```
quartus_eda <project name> --simulation --tool=ncsim --format=verilog
```

To summarize, for the three operating conditions the steps above generate the following files in the simulation output directory:

First slow corner (slow, 1100 mV, 85° C):

VO file— <revision name>.vo

SDO file— <revision name>\_v.sdo

Second slow corner (slow, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_slow.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_slow.sdo*

Fast corner (fast, 1100 mV, 0° C):

VO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_fast.vo*

SDO file— *<revision name>\_<speedgrade>\_1100mv\_0c\_v\_fast.sdo*

## Perform Timing Simulation Using Post-Synthesis Netlist

You can perform a timing simulation using the post-synthesis netlist instead of using a gate-level netlist and you can generate a Standard Delay Format Output File (.sdo) without running the Fitter. In this case, the SDO file includes all timing values for the device cells only.

Interconnect delays are not included because fitting (placement and routing) has not been performed.

To generate the post-synthesis netlist and the SDO file, type the following at a command prompt:

```
quartus_map <project name> -c <revision name> ␣
quartus_tan <project name> -c <revision name> --post_map --zero_ic_delays ␣
quartus_eda <project name> -c <revision name> --simulation --tool= \
  <3rd party EDA tool> --format=<HDL language> ␣
```

For more information on the `-format` and `-tool` options, type the following command at a command prompt:

```
quartus_eda -help=<options> command ␣
```

## Quartus II Timing Simulation Libraries

Altera device simulation library files are provided in the *<Quartus II installation>/eda/sim\_lib* directory. The Verilog Output File or VHDL Output File requires the library for the device your design targets. For example, the Stratix device family requires the following library files:

- **stratix\_atoms.v**
- **stratix\_atoms.vhd**
- **stratix\_components.vhd**

If your design targets a Stratix device, you must set up the appropriate mappings in your `cds.lib` file. Refer to “[Create Libraries](#)” for more information.

## Create Libraries

Create the following libraries for your simulation:

- Work library
- Device family libraries targeting using the following files in the *<path to Quartus II installation>/eda/sim\_lib* directory:
  - *<device\_family>\_atoms.v*
  - *<device\_family>\_atoms.vhd*
  - *<device\_family>\_components.vhd*

For step-by-step instructions on creating libraries, refer to “Basic Library Setup” on page 4–7 and “LPM Functions, Altera Megafunctions, and Altera Primitives Libraries” on page 4–9.

## Compile the Project Files and Libraries

Compile the project files and libraries into your work directory using the **ncvlog** or **ncvhdl** programs or the GUI. Include the following files:

- Test bench file
- The Quartus II software functional output netlist file (Verilog Output File or VHDL Output File)
- Atom library file for the device family *<device family>\_atoms.<v | vhd>*
- For VHDL, *<device family>\_components.vhd*

For instructions on compiling, refer to “Compile Source Code and Testbenches” on page 4–13.

## Elaborate Your Design

When performing elaboration with the Quartus II-generated Verilog HDL netlist file, the Standard Delay Format Output File is read automatically. When you run **ncelab**, it recognizes the embedded system task `$sdf_annotate` and automatically compiles and annotates the Standard Delay Format Output File (runs **ncsdfc** automatically).

The Standard Delay Format Output File should be located in the same directory where you invoke an elaboration or simulation, because the `$sdf_annotate` task references the Standard Delay Format Output File without using a full path. If you are invoking an elaboration or simulation from a different directory, you can either comment out the `$sdf_annotate` and annotate the Standard Delay Format Output File with the GUI, or add the full path of the Standard Delay Format Output File.

Refer to “Elaborate Your Design” on page 4–15 for step-by-step instructions on elaboration.

For VHDL, the Quartus II software-generated VHDL netlist file does not contain system task calls to locate your SDF file; therefore, you must compile the Standard Delay Format Output File manually. Refer to “Compiling the Standard Delay Output File (VHDL Only) in Command-Line Mode” and “Compiling the Standard Delay Output File (VHDL Only) in GUI Mode” for information about compiling the Standard Delay Format Output File.

### *Compiling the Standard Delay Output File (VHDL Only) in Command-Line Mode*

To annotate the Standard Delay Format Output File timing data from the command line, perform the following steps:

1. Compile the Standard Delay Format Output File using the `ncsdfc` program by typing the following command at the command prompt:

```
ncsdfc <project name>_vhd.sdo -output <output name> ↵
```

The `ncsdfc` program generates an `<output name>.sdf.X` compiled SDO.

If you do not specify an output name, `ncsdfc` uses `<project name>.sdo.X`.

2. Specify the compiled Standard Delay Format Output File for the project by adding the following command to an ASCII SDF command file for the project:

```
COMPILED_SDF_FILE = "<project name>.sdf.X" SCOPE = <instance path>
```

The following code shows an example of an SDF command file:

```
// SDF command file sdf_file
COMPILED_SDF_FILE = "lpm_ram_dp_test_vhd.sdo.X",
SCOPE = :tb,
MTM_CONTROL = "TYPICAL",
SCALE_FACTORS = "1.0:1.0:1.0",
SCALE_TYPE = "FROM_MTM";
```

After you compile the Standard Delay Format Output File, run the following command to elaborate the design:

```
ncelab worklib.<project name>:entity -SDF_CMD_FILE <SDF Command File> ↵
```

### *Compiling the Standard Delay Output File (VHDL Only) in GUI Mode*

To annotate the SDO file timing data in the GUI, perform the following steps in the NCLaunch window:

1. On the Tools menu, click **SDF Compiler**. The **Compile SDF** dialog box appears.
2. In the **SDF File** box, type in the name of the Standard Delay Format Output File (.sdo) for the project.
3. Click **OK**.

When the Standard Delay Format Output File compilation is complete, you can elaborate the design. Refer to “[Elaboration in GUI Mode](#)” on page 4–16 for step-by-step instructions.

If you are performing a VHDL gate-level simulation, you must create an SDF command file before you begin elaboration. To create the SDF command file, perform steps 5 through 11.

4. On the Tools menu, click **Elaborator**. The **Elaborate** dialog box appears.
5. Click **Advanced Options**.
6. Click **Annotation**.
7. Turn on **Use SDF File**.
8. Click **Edit**.
9. Browse to the location of the SDF command file name.
10. Click **Add** and browse to the location of the Standard Delay Format Output File in the **Compiled SDF File** box and click **OK**.
11. Click **OK** to save and exit the **SDF Command File** dialog box.

### **Add Signals to View**

Refer to the section “[Add Signals to View](#)” on page 4–17 for information about adding signals to view.

## Simulate Your Design

Simulate your design using the `ncsim` program as described in “Simulate Your Design” on page 4–20.

For the design examples to run gate-level timing simulation, refer to [www.altera.com/support/examples/ncsim/exm-ncsim.html](http://www.altera.com/support/examples/ncsim/exm-ncsim.html).

## Simulating Designs that Include Transceivers

If your design includes a Stratix II GX or Stratix GX transceiver, you must compile additional library files to perform functional or timing simulations.

### Stratix GX Functional Simulation

To perform a functional simulation of your design that instantiates the `altgxb` megafunction, enabling the gigabit transceiver block (GXB) on Stratix GX devices, compile the `stratixgx_mf` model file into the `altgxb` library.

The `stratixgx_mf` model file references the `lpm` and `sgate` libraries, so you will need to create these libraries to perform a simulation.

#### *Example of Compiling Library Files for Functional Stratix GX Simulation in Verilog HDL*

To compile the libraries necessary for a functional simulation of a Verilog HDL design targeting a Stratix GX device, type the following commands at the NC Sim command prompt:

```
ncvlog -work lpm 220model.v ←
ncvlog -work altera_mf altera_mf.v ←
ncvlog -work sgate sgate.v ←
ncvlog -work altgxb stratixgx_mf.v ←
ncsim work.<my design> ←
```

#### *Example of Compiling Library Files for Functional Stratix GX Simulation in VHDL*

To compile the libraries necessary for functional simulation of a VHDL design targeting a Stratix GX device, type the following commands at the NC-Sim command prompt:

```
ncvhdl -work lpm 220pack.vhd 220model.vhd ←
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd ←
ncvhdl -work sgate sgate_pack.vhd sgate.vhd ←
ncvhdl -work altgxb stratixgx_mf.vhd stratixgx_mf_components.vhd ←
```

```
ncsim work.<my design> ←
```

## Stratix GX Post-Fit (Timing) Simulation

To perform a post-fit timing simulation of your design that includes a Stratix GX transceiver, compile the **stratixgx\_atoms** and **stratixgx\_hssi\_atoms** model files into the **stratixgx** and **stratixgx\_gxb** libraries, respectively.

You need to create these libraries to perform a simulation because the **stratixgx\_hssi\_atoms** model file references the **lpm** and **sgate** libraries.

### *Example of Compiling Library Files for Timing Stratix GX Simulation in Verilog HDL*

To compile the libraries necessary to timing simulation of a Verilog HDL design targeting a Stratix GX device, type the following commands at the NC-Sim command prompt:

```
ncvlog -work lpm 220model.v ←  
ncvlog -work altera_mf altera_mf.v ←  
ncvlog -work sgate sgate.v ←  
ncvlog -work stratixgx stratixgx_atoms.v ←  
ncvlog -work stratixgx_gxb stratixgx_hssi_atoms.v ←  
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 \  
-PULSE_INT_R 0 ←
```

### *Example of Compiling Library Files for Timing Stratix GX Simulation in VHDL*

To compile the libraries necessary for timing simulation of a VHDL design targeting a Stratix GX device, type the following commands at the NC-Sim command prompt:

```
ncvhdl -work lpm 220pack.vhd 220model.vhd ←  
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd ←  
ncvhdl -work sgate sgate_pack.vhd sgate.vhd ←  
ncvhdl -work stratixgx stratixgx_atoms.vhd stratixgx_components.vhd ←  
ncvhdl -work stratixgx_gxb stratixgx_hssi_atoms.vhd \  
stratixgx_hssi_components.vhd ←  
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0 ←
```

## Stratix II GX Functional Simulation

To perform a post-fit timing simulation of your design that instantiates the `alt2gxb` megafunction, edit your `cds.lib` file so that all the libraries point to the work library, and compile the `stratixiigx_hssi` model file into the `stratixiigx_hssi` library. When compiling the library files, you can safely ignore the following warning message:

```
"Multiple logical libraries mapped to a single location"
```

The following example is of the `cds.lib` file.

---

### Example 4-1. Example of a `cds.lib` File

```
SOFTINCLUDE ${CDS_INST_DIR}/tools/inca/files/cdsvhdl.lib
SOFTINCLUDE ${CDS_INST_DIR}/tools/inca/files/cdsvlog.lib
DEFINE work ./ncsim_work
DEFINE stratixiigx_hssi ./ncsim_work
DEFINE stratixiigx ./ncsim_work
DEFINE lpm ./ncsim_work
DEFINE sgate ./ncsim_work
```

---

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries, so you will need to create these libraries to perform a simulation.

Generate a functional simulation netlist by turning on **Create a simulation library for this design** in the last page of the `alt2gxb` MegaWizard (Figure 4-7). The `<alt2gxb entity name>.vho` or `<alt2gxb module name>.vo` is generated in the current project directory.

Figure 4-7. alt2gxb MegaWizard

 The Quartus II generated alt2gxb functional simulation library file references stratixigx\_hssi wysiwyg atoms.

### Example of Compiling Library Files for Functional Stratix II GX Simulation in Verilog HDL

To compile the libraries necessary to functional simulation of a Verilog HDL design targeting a Stratix II GX device, type the following commands at the NC-Sim command prompt:

```

ncvlog -work lpm 220model.v ←
ncvlog -work altera_mf altera_mf.v ←
ncvlog -work sgate sgate.v ←
ncvlog -work stratixigx_hssi stratixigx_hssi_atoms.v ←
    
```

```
ncvlog -work work <alt2gxb module name>.vo ←
ncelab work.<my design> ←
```

### *Example of Compiling Library Files for Functional Stratix II GX Simulation in VHDL*

To compile the libraries necessary for functional simulation of a VHDL design targeting a Stratix II GX device, type the following commands at the NC-Sim command prompt:

```
ncvhdl -work lpm 220pack.vhd 220model.vhd ←
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd ←
ncvhdl -work sgate sgate_pack.vhd sgate.vhd ←
ncvhdl -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd ←
ncvhdl -work work <alt2gxb entity name>.vho ←
ncelab work.<my design> ←
```

### **Stratix II GX Post-Fit (Timing) Simulation**

To perform a post-fit timing simulation of your design that includes the `alt2gxb` megafunction, edit your `cds.lib` file so that all the libraries point to the work library and compile `stratixiigx_atoms` and `stratixiigx_hssi_atoms` into the `stratixiigx` and `stratixiigx_hssi` libraries, respectively. When compiling the library files, you can safely ignore the following warning message:

```
"Multiple logical libraries mapped to a single location"
```

For an example of a `cds.lib` file, refer to [“Stratix II GX Functional Simulation” on page 4–33](#).

The `stratixiigx_hssi_atoms` model file references the `lpm` and `sgate` libraries, so you will need to create these libraries to perform a simulation.

### *Example of Compiling Library Files for Timing Stratix II GX Simulation in Verilog HDL*

To compile the libraries necessary to timing simulation of a Verilog HDL design targeting a Stratix II GX device, type the following commands at the NC-Sim command prompt:

```
ncvlog -work lpm 220model.v ←
ncvlog -work altera_mf altera_mf.v ←
ncvlog -work sgate sgate.v ←
ncvlog -work stratixiigx stratixiigx_atoms.v ←
ncvlog -work stratixiigx_hssi stratixiigx_hssi_atoms.v ←
```

```
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0 ←
```

### Example of Compiling Library Files for Timing Stratix II GX Simulation in VHDL

To compile the libraries necessary for timing simulation of a VHDL design targeting a Stratix II GX device, type the following commands at the NC-Sim command prompt:

```
ncvhdl -work lpm 220pack.vhd 220model.vhd ←
ncvhdl -work altera_mf altera_mf_components.vhd altera_mf.vhd ←
ncvhdl -work sgate sgate_pack.vhd sgate.vhd ←
ncvhdl -work stratixiigx stratixiigx_atoms.vhd \
stratixiigx_components.vhd ←
ncvhdl -work stratixiigx_hssi stratixiigx_hssi_components.vhd \
stratixiigx_hssi_atoms.vhd ←
ncvhdl -work work <alt2gxb>.vho ←
ncelab work.<my design> -TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0 ←
```

## Pulse Reject Delays

By default, the NCSim software filters out all pulses that are shorter than the propagation delay between primitives. Setting the pulse reject delays (similar to transport delays) options in the NC-Sim software prevents the simulation tool from filtering out these pulses. Use the following options to ensure that all signal pulses are seen in the simulation results.

### -PULSE\_R

Use this option when the pulses in your simulation are shorter than the delay within a gate-level primitive. The argument is the percentage of delay for pulse reject limit for the path.

### -PULSE\_INT\_R

Use this option when the pulses in your simulation are shorter than the interconnect delay between gate-level primitives. The argument is the percentage of delay for pulse reject limit for the path. The -PULSE\_R and -PULSE\_INT\_R options are also used by default in the NativeLink® feature for gate-level timing simulation.

The following NC-Sim software command describes the command-line syntax to perform a gate-level timing simulation with the device family library:

```
ncelab worklib.<project name>:entity -SDF_CMD_FILE <SDF Command File> \
-TIMESCALE 1ps/1ps -PULSE_R 0 -PULSE_INT_R 0
```

## Using the NativeLink Feature with NC-Sim

The NativeLink feature in the Quartus II software facilitates the seamless transfer of information between the Quartus II software and EDA tools and allows you to run NC-Sim within the Quartus II software.

### Setting Up NativeLink

To run NC-Sim automatically from the Quartus II software using the NativeLink feature, you must specify the path to your simulation tool by performing the following steps:

1. On the Tools menu, click **Options**. The **Options** dialog box appears.
2. In the **Category** list, select **EDA Tool Options**. The **EDA Tool Options** page is shown.
3. Double-click the entry under the **Location of executable** column beside the name of your **EDA Tool**, and type or browse to the directory containing the executables of your EDA tool.
4. Click **OK**.

You can also specify the path to the simulator's executables by using the `set_user_option` TCL command:

```
set_user_option -name EDA_TOOL_PATH_NCSIM <path to executables>
```

### Performing an RTL Simulation Using NativeLink

To run a functional RTL simulation with the NC-Sim software automatically in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears (Figure 4-8).

Figure 4–8. Simulation Page in the Settings Dialog Box

3. In the **Tool name** list, select **NCSim**.
4. If your design is written entirely in Verilog HDL or in VHDL, the NativeLink feature automatically chooses the correct language and Altera simulation libraries. If your design is written with mixed languages, the NativeLink feature uses the default language specified in the **Format for output netlist** list. To change the default

language when there is a mixed language design, under **EDA Netlist Writer options**, in the **Format for output netlist** list, select **VHDL** or **Verilog**. [Table 4–8](#) shows the design languages for output netlists and simulation models.

<b>Design File</b>	<b>Format for Output Netlist</b>	<b>Simulation Models Used</b>
Verilog	Any	Verilog
VHDL	Any	VHDL
Mixed	Verilog	Verilog
Mixed	VHDL	VHDL

For mixed language simulation, choose the same language that was used to generate your megafunctions to ensure correct parameter passing between the megafunctions and the Altera libraries. For example, if your altsyncram megafunction was generated in VHDL, choose VHDL as the format for output netlist.

For mixed language simulations, it is important to be aware of the following conditions:

- VHDL designs instantiating Verilog user-defined primitives (UDPs) are not supported.
  - Parameters cannot be passed in Verilog modules that instantiate VHDL components.
5. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.

For more information about setting up a testbench with NativeLink, refer to the section [“Setting Up a Testbench” on page 4–40](#).

6. Click **OK**.
7. On the Processing menu, point to Start and click **Start Analysis and Elaboration** to perform an analysis and elaboration. This command collects all your file name information and builds your design hierarchy in preparation for simulation.
8. On the Tools menu, point to **EDA Simulation Tool** and click **Run EDA RTL Simulation** to automatically run NC-Sim, compile all necessary design files, and complete a simulation.

## Performing a Gate Level Simulation Using NativeLink

To run a gate-level timing simulation with the NC-Sim software in the Quartus II software, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** appears (Figure 4–8 on page 4–38).
3. In the **Tool name** list, select **NCSim**.
4. Under **EDA Netlist Writer options**, in the **Format for output netlist** list, choose **VHDL** or **Verilog**. You can also modify where you want the post-synthesis netlist generated by editing or browsing to a directory in the **Output directory** box.
5. To perform a gate level simulation after each full compilation, turn on **Run Gate Level Simulation automatically after compilation**.
6. If you have testbench files or macro scripts, enter the information under **NativeLink settings**.
7. Click **OK**.
8. On the Processing menu, point to Start and click **Start EDA Netlist Writer** to generate a simulation netlist of your design.
9. On the Tools menu, point to EDA Simulation Tool and click **Run EDA Gate Level Simulation** to automatically run NC-Sim, compile all necessary design files, and complete a simulation.

A Tcl File (\*.tcl) is generated in the `<project_directory>\simulation\ncsim` directory when you run NativeLink. This TCL File enables you to simulate the design with the following command without using NativeLink:

```
quartus_sh -t <project_directory>\simulation\ncsim\<generated_do_file>.tcl
```

## Setting Up a Testbench

You can compile your design files and testbench files, and run EDA simulation tools to perform a simulation automatically using the NativeLink feature.

To setup NativeLink with a testbench, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. Under **NativeLink settings**, select **None** or **Compile test bench** (Table 4–9).

<b>Table 4–9. NativeLink Settings</b>	
<b>Settings</b>	<b>Description</b>
None	Compile simulation models and design files.
Compile test bench	NativeLink compiles simulation models, design files, testbench files, and starts simulation.

4. If you select **Compile test bench**, select your testbench setup from the **Compile test bench** list. You can use different testbench setups to specify different testbench files for different test scenarios. If there are no testbench setups entered, create a testbench setup by performing the following steps:
  - a. Click **Test Benches**. The **Test Benches** dialog box appears.
  - b. Click **New**. The **New Test Bench Settings** dialog box appears.
  - c. In the **Test Bench name** box, type in the testbench setup name which is used to identify the different testbench setups.
  - d. In the **Test bench entity** box, type in the top-level entity name. For example, for a Quartus II generated VHDL testbench, type `filtref_vhd_vec_tst`.
  - e. In the **Instance** box, type in the full instance path to the top level of your FPGA design. For example, for a Quartus II generated VHDL testbench, type `i1`.
  - f. Under **Simulation period**, select **Run simulation until all vector stimuli are used**. If you select **End simulation at**, specify the simulation end time and the time unit.

- g. Under **Test bench files**, browse and add all your testbench files in the **File name** box. Use the **Up** and **Down** button to reorder your files. The script used by NativeLink compiles the files in the order from top to the bottom.

You can also specify the library name and the HDL version to compile the testbench file. NativeLink compiles the testbench to the library name of the HDL specified version.

- h. Click **OK**.
  - i. In the **Test Benches** dialog box, click **OK**.
5. Under **NativeLink settings**, you can turn on **Use script to setup simulation** and browse to your script. You can write a script to setup your waveforms before running the simulation.

The script should be a valid NC-Sim tcl script. NativeLink passes the script to ncsim command with command-line arguments to set up and run simulation.

### *Creating a Testbench*

In the Quartus II software, you can create a Verilog HDL or VHDL testbench from a Vector Waveform File. The generated testbench includes the behavior of the input stimulus and applies it to your instantiated top-level FPGA design.

1. On the File menu, click **Open**. The **Open** dialog box appears.
2. Click the **Files of type** arrow and select **Waveform/Vector Files**. Select your file.
3. Click **Open**.
4. On the File menu, click **Export**. The **Export** dialog box.
5. Click the **Save as type** arrow and select **VHDL Test Bench File (\*.vht)** or **Verilog Test Bench File (\*.vt)**.
6. You can turn on **Add self-checking code to file** to check your simulation results against your Vector Waveform File.
7. Click **Export**.

## Incorporating PLI Routines

Designers frequently use PLI routines in Verilog HDL testbenches to perform user- or design-specific functions that are beyond the scope of the Verilog HDL language. Cadence NC simulators include the PLI wizard, which helps you incorporate your PLI routines.

For example, if you are using the Quartus II software version 5.0 and earlier, and you are using a Hexadecimal (Intel-Format) File for memory, you can convert it for use with NC tools using the Altera-provided **convert\_hex2ver** function. To use this function, you must build it and place it in your project directory using the PLI wizard.

This section describes how to dynamically link, dynamically load, and statically link a PLI library using the **convert\_hex2ver** function as an example. The following **convert\_hex2ver** source files are located in the *<path to Quartus II installation>/eda/cadence/verilog-xl* directory:

- **convert\_hex2ver.c**
- **veriuser.c**

### Dynamically Link a PLI Library

To create a PLI dynamic library (.so or .sl), perform the following steps:

1. Run the PLI wizard by typing `pliwiz` at the command prompt.
2. In the **Config Session Name and Directory** page, type the name of the session in the **Config Session Name** box and type the directory in which the file should be built in the **Config Session Directory** box.
3. Click **Next**.
4. In the **Select Simulator/Dynamic Libraries** page, turn on the **Dynamic Libraries Only** option.
5. Click **Next**.
6. In the **Select Components** page, select the **PLI 1.0 Applications** option, and then select **libpli**.
7. Click **Next**.
8. In the **Select PLI 1.0 Application Input** page, select **Existing VERIUSER** (source/object file).
9. Select **Source File** and click **Browse** to locate the **veriuser.c** file provided with the Quartus II software.

The **veriuser.c** file is located in the following directory:

*<path to Quartus II installation>/eda/cadence/verilog-xl*

10. Click **Next**.
11. In the **PLI 1.0 Application** page, click **Browse** under **PLI Source Files** to locate the **convert\_hex2ver.c** file.
12. Click **Next**.
13. In the **Select Compiler** page, choose your **C** compiler from the **Select Compiler list** box.

gcc is an example of a C compiler. To allow the **PLIWIZ** wizard to find your C compiler, ensure your path variable is set correctly.

14. Click **Next**.
15. Click **Finish**.
16. To build your targets now, click **Yes**.
17. Compilation creates the file **libpli.so** (**libpli.dll** for PCs), which is your PLI dynamic library, in your session directory. When you elaborate your design, the elaborator looks through the path specified in the **LD\_LIBRARY\_PATH** (UNIX) or **PATH** (PCs) environment variable, searches for the **.so** and **.dll** files, and loads them when needed.

You must modify **LD\_LIBRARY\_PATH** or **PATH** to include the directory location of your **.so** and **.dll** files.

## Dynamically Load a PLI Library

To create a PLI library to be loaded with the NC-Sim software, perform the following steps:

1. Open the **veriuser.c** file located in the following directory:

*<path to Quartus II installation>/eda/cadence/verilog-xl*

The following two examples are sections of the original and modified **veriuser.c** file. The first example is the original **veriuser.c** file packaged with the Quartus II software. The second example is a **veriuser.c** file modified for dynamic loading.

### Original veriuserc File

```
s_tfcell veriusertfs[] =
{
    /*** Template for an entry:
    { usertask|userfunction, data,
      checktf(), sizetf(), calltf(), misctf(),
      "$tfname", forwref?, Vtool?, ErrMsg? },
    Example:
    {usertask, 0, my_check, 0, my_func, my_misctf, "$my_task" },
    ***/
    /*** add user entries here ***/
    /* This Handles Binary bit patterns */
    {usertask, 0, 0, 0, convert_hex2ver, 0, "$convert_hex2ver",
    1},

        {0} /*** final entry must be 0 ***/
};
```

### Modified veriuserc File

```
p_tfcell my_bootstrap ()
{

static s_tfcell my_tfs[] =
/*s_tfcell veriusertfs[] = */
{
    /*** Template for an entry:
    { usertask|userfunction, data,
      checktf(), sizetf(), calltf(), misctf(),
      "$tfname", forwref?, Vtool?, ErrMsg? },
    Example:
    { usertask, 0, my_check, 0, my_func, my_misctf, "$my_task" },
    ***/
    /*** add user entries here ***/
    /* This Handles Binary bit patterns */
    {usertask, 0, 0, 0, convert_hex2ver, 0, "$convert_hex2ver",
    1},

        {0} /*** final entry must be 0 ***/
};
return(my_tfs);
}
```

2. Run the PLI wizard by typing `pliwiz` at a command prompt, or on the Utilities menu by clicking **PLI Wizard** in the NCLaunch window.
3. In the **Config Session Name and Directory** page, type the name of the session in the **Config Session Name** box and type the directory in which the file should be built in the **Config Session Directory** box.
4. Click **Next**.

5. In the **Select Simulator/Dynamic Libraries** page, select the **Dynamic Libraries Only** option.
6. Click **Next**.
7. In the **Select Components** page, turn on the **PLI 1.0 Applications** option, and select **loadpli1**.
8. Click **Next**.
9. Type a name into the **Bootstrap Function(s)** box.  
  
For example, type `my_bootstrap` into the **Bootstrap Function(s)** box.
10. Type the name of your generated dynamic library into the **Dynamic Library** box.  
  
For example, type `convert_dyn_lib` into the **Dynamic Library** box to generate a dynamic library named **convert\_dyn\_lib.so**.
11. In the **PLI 1.0 Application** page, click **Browse** under **PLI Source Files** to locate the `convert_hex2ver.c` file and the modified `veriusers.c` file.
12. Click **Next**.
13. In the **Select Compiler** page, select your C compiler from the **Select Compiler** list box.  
  
`gcc` is an example of a C compiler. To allow the **PLIWIZ** wizard to find your C compiler, ensure your Path variable is set correctly.
14. Click **Next**.
15. Click **Finish**.
16. To build your targets now, click **Yes**.

Compilation generates your dynamic library, `cmd_file.nc`, and `cmd_file.xl` files into your local directory. The `cmd_file.nc` and `cmd_file.xl` files contain command line options to use with your newly generated dynamic library file.

- Use the `cmd_file.nc` command file with `ncelab` to perform your simulations, as shown in the following example:

```
ncelab worklib.mylpmrom -FILE cmd_file.nc ↵
```

- Use the `cmd_file.xl` command file with `verilog-xl` or `ncverilog` to perform your simulations, as shown in the following example:

```
ncverilog -f cmd_file.xl ↵  
verilog -f cmd_file.xl ↵
```

### Statically Link the PLI Library with NC-Sim

To statically link the PLI library with NC-Sim software, perform the following steps:

1. Run the PLI wizard by typing `pliwiz` at the command prompt, or on the Utilities menu by clicking **PLI Wizard** in the NCLaunch window.
2. In the **Config Session Name** and **Directory** page, type the name of the session in the **Config Session Name** box and type the directory in which the file should be built in the **Config Session Directory** box.
3. Click **Next**.
4. Select **NC Simulators** and select **NC-verilog**.
5. Click **Next**.
6. In the **Select Components** page, turn on the **PLI 1.0 Applications option** and select **Static**.
7. In the **Select PLI 1.0 Application Input** page, select **Existing VERIUSER** (source/object file).

8. Select **Source File** and click **Browse** to locate the **veriuser.c** file provided with the Quartus II software.

The **veriuser.c** file is found in the following location:

```
<path to Quartus II installation>/eda/cadence/verilog-xl
```

9. Click **Next**.
10. In the **PLI 1.0 Application** page, click **Browse** under **PLI Source Files** to locate the **convert\_hex2ver.c** file.
11. Click **Next**.
12. In the **Select Compiler** page, select your C compiler from the **Select Compiler** list box.

**gcc** is an example of a C compiler. To allow the **PLIWIZ** to find your C compiler, ensure your Path variable is set correctly.

13. Click **Next**.
14. Click **Finish**.
15. To build your targets now, click **Yes**.

Compilation generates **ncelab** and **ncsim** executables into your local directory. These executables replace the original **ncelab** and **ncsim** executables.

**ncverilog** users can use the following command to perform simulation with the newly generated **ncelab** and **ncsim** executables.

```
ncverilog +ncelabexe+<path to ncelab> +ncsimexe+<path to ncelab> <design files> ↵
```

The following example shows how an **ncverilog** users can perform a simulation with the newly generated **ncelab** and **ncsim** executables:

```
ncverilog +ncelabexe+./ncelab +ncsimexe+./ncsim my_ram.vt my_ram.v -v altera_mf.v ↵
```

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting chapter* in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting chapter* in volume 2 of the *Quartus II Handbook*.

## Generate NC-Sim Simulation Output Files

You can generate Verilog Output File and Standard Delay Format Output File simulation output files with Tcl commands or at a command prompt.

For more information about generating Verilog Output File simulation output files and Standard Delay Format Output File simulation output files, refer to [“Quartus II Simulation Output Files” on page 4–22](#).

### *Tcl Commands:*

The following three assignments cause a Verilog HDL netlist to be written out when you run the Quartus II netlist writer. The netlist has a 1 ps timing resolution for the NC-Sim Simulation software.

```
set_global_assignment -name EDA_OUTPUT_DATA_FORMAT VERILOG -section_id eda_simulation
set_global_assignment -name EDA_TIME_SCALE "1 ps" -section_id eda_simulation
set_global_assignment -name EDA_SIMULATION_TOOL "NC-Verilog (Verilog)"
```

Use the following Tcl command to run the Quartus II netlist writer:

```
execute_module -tool eda
```

### *Command Prompt*

Use the following command to generate a simulation output file for the Cadence NC-Sim software simulator. Specify Verilog HDL or VHDL for the format.

```
quartus_eda <project name> --simulation --format=<verilog|vhdl> --tool=ncsim ←
```

## Conclusion

The Cadence NC family of simulators work within an Altera FPGA design flow to perform functional/RTL, post-synthesis, and gate-level timing simulation, easily and accurately.

Altera provides functional models of LPM and Altera-specific megafunctions that you can compile with your testbench or design. For timing simulation, use the atom netlist file generated by Quartus II compilation.

The seamless integration of the Quartus II software and Cadence NC tools make this simulation flow an ideal method for fully verifying an FPGA design.

August 2004 v2.1	<ul style="list-style-type: none"> <li>● New functionality for Quartus II software 4.1 SP1.</li> </ul>	—
June 2004 v2.0	<ul style="list-style-type: none"> <li>● Updates to tables and figures.</li> <li>● New functionality for Quartus II software 4.1.</li> </ul>	—
February 2004 v1.0	Initial release.	—

## 5. Simulating Altera IP in Third-Party Simulation Tools

QII53014-7.2.0

### Introduction

The capacity and complexity of Altera® FPGAs continues to increase as the need for intellectual property (IP) becomes increasingly critical. Using IP megafunctions reduces the design and verification time, allowing you to focus on design customization. Altera and the Altera Megafunction Partners Program (AMPP<sup>SM</sup>) offer a broad portfolio of IP megafunctions optimized for Altera FPGAs. Through parameterization, these reusable blocks of IP can be customized to meet your design requirements.

Even when the IP source code is encrypted or otherwise restricted, Altera's Quartus® II software allows you to easily simulate designs that contain Altera IP. With the Quartus II software, you can custom configure IP designs, then generate a VHDL or Verilog HDL functional simulation model to use with your choice of simulation tools.

This chapter provides an overview of the process for instantiating the IP megafunctions in your design and simulating its' functional simulation model in an Altera-supported, third-party simulation tool. In this chapter, IP megafunctions refer to Altera megafunctions, IP MegaCore® functions and IP AMPP megafunctions. All IP MegaCore functions come with IP functional simulations (IPFS) models to support functional simulation. Some Altera megafunctions and some AMPP megafunctions also require IPFS models for functional simulation.

### IP Functional Simulation Flow

The IP megafunction's MegaWizard® interface allows you to quickly and easily view documentation, specify parameters, generate an IP functional simulation (IPFS) model, and output the files necessary to integrate a parameterized IP megafunction into your design. Within the Quartus II software, the MegaWizard Plug-In Manager can be used to select and parameterize your choice of IP megafunctions. The Quartus II software generates an IP megafunction's variation file that is included in your Quartus II project. For IP megafunctions that require IPFS models, Quartus II software can also generate a Verilog Output File (.vo) or VHDL Output File (.vho) that contains a Register Transfer Level (RTL) IPFS model after you have parameterized the megafunction. IPFS models are written to the Quartus II project directory.

Most Altera megafunctions and IP MegaCore functions support functional simulation in Verilog and VHDL for all Altera supported third-party simulators. Simulation libraries are required to simulate IP megafunctions. Refer to [Table 5-2 on page 5-10](#) for a subset of simulation libraries supplied with the Quartus II software.

[Figure 5-1](#) shows a typical simulation flow for Altera IP with third-party simulators.

**Figure 5-1. IP Functional Simulation (IPFS) Model Design Flow**

### Verilog and VHDL IP Functional Simulation (IPFS) Models

Some IP megafunctions require IPFS models to support functional simulation. These IPFS models are written in high-level Register Transfer Level (RTL) HDL. These high-level RTL models in Verilog or VHDL format differ from the low-level synthesized netlist in Verilog or VHDL format generated by the Quartus II software for post-synthesis or post place-and-route simulations. The IPFS models generated by the

Quartus II software are much faster than the low-level post-synthesis or post place-and-route netlists of your design because they are mapped to higher-level primitives such as adders, multipliers, and multiplexers. These IPFS models can be simulated together with the rest of your design in any Altera-supported simulator. Altera recommends that you generate IPFS models in the same hardware language as the IP megafunction's variation file hardware language.

You can use an IPFS model for simulation only, and not for synthesis or any other purpose. Attempting to synthesize an IPFS model will result in a nonfunctional design.

Generating an IPFS model for Altera MegaCore functions does not require a license. However, generating an IPFS model for AMPP megafunctions may require a license. For more information on licensing requirements, contact the IP megafunction vendor.

For details about how to parameterize and generate an IP, refer to the applicable IP user guide.

## Instantiate the IP in Your Design

For each IP megafunction in your design, you must instantiate the corresponding entity or module in your design. Each IP megafunction entity or module name is defined in its Quartus II generated megafunction variation file. After instantiating the IP megafunction in your design, you do not need to edit your design for synthesis or simulation.

To synthesize your design using the Quartus II software, add the Quartus II-generated Verilog HDL or VHDL variation file to your Quartus II project. When you create new variation files for a Quartus II project, they are added to the current open project when the megafunction is generated.

To synthesize your design using a third-party EDA tool, add the Quartus II-generated CMP file (*<megafunction variation>.cmp*) for your VHDL design or the Verilog HDL black box file (*<megafunction variation>\_bb.v*) for your Verilog HDL design to your third-party synthesis project.

For more information about synthesis and compilation with the Quartus II software, refer to the applicable chapters in volume 1 of the *Quartus II Handbook*.

## Perform Simulation

To perform simulation, in addition to adding your design files and testbench files, you also have to add the IP megafunction's variation file or IPFS model to your simulation project. If the IP megafunction does not require an IPFS model for simulation, add the megafunctions' variation file to your simulation project. If the IP megafunction you are simulating requires an IPFS model, then add the IPFS model to your simulation project. Your simulation project will also require Altera-supplied libraries for successful simulation. Figure 5–2 shows how the Altera libraries are used in IP functional simulation.

**Figure 5–2. IP Functional Simulation Library Usage**

The Quartus II software contains all the libraries required for setting up and running a successful simulation of Altera IP. You can use the Quartus II NativeLink feature to set up your simulation if the IP megafunction you are using supports Quartus II NativeLink. Refer to the applicable IP megafunction user guide to determine if the IP megafunction supports the NativeLink feature in the Quartus II software. Alternatively, you can simulate Altera IP with third-party simulators directly.

### Simulating Altera IP Using the Quartus II NativeLink Feature

The Quartus II NativeLink feature eases the task of setting up and running a simulation. The NativeLink feature lets you launch the third-party simulator to perform simulation from within the Quartus II software. The NativeLink feature automates the compilation and simulation of testbenches.

The following list briefly describes the steps to simulate IP megafunctions with third-party simulators using the Quartus II NativeLink feature. Each of these steps is described in more detail in the sections that follow.

1. [Set up a Quartus II Project.](#)
2. [Select the Third-Party Simulation Tool.](#)
3. [Specify the Path for the Third-Party Simulator.](#)
4. [Specify the Testbench Settings.](#)
5. [Analyze and Elaborate the Quartus II Project.](#)
6. [Run RTL Functional Simulation.](#)

### *Set up a Quartus II Project*

To simulate IP megafunctions with the Quartus II NativeLink feature, you must open an existing project or create a new project in the Quartus II software. You can create and parameterize the IP you want to use in your design using MegaWizard Plug-In Manager within the Quartus II software. Altera IP megafunction variation files are added to your Quartus II project when you create and parameterize the IP. You can also add any other required design files to your Quartus II project. If you are using the Quartus II NativeLink feature and your Quartus II project contains IP megafunctions that require IPFS models for simulation, you do not have to manually add the IPFS models to the Quartus II project for these IP megafunctions. When the Quartus II NativeLink feature launches the third-party simulator tool and starts the simulation, it automatically adds the IPFS model files required for simulation as long as they are present in the Quartus II project directory.

### *Select the Third-Party Simulation Tool*

You can select the third-party simulation tool from the Project Settings menu, as shown in [Figure 5-3](#).

**Figure 5–3. Selecting Third-Party Simulator Tools**

Table 5–1 lists the third-party simulators supported by the Quartus II NativeLink feature.

<b>Table 5–1. Third-Party Simulator Support with the Quartus II NativeLink Feature</b>			
<b>Third-Party Simulator</b>	<b>Can be Launched from Quartus II</b>	<b>Testbench Support</b>	<b>Mixed Design (Verilog and VHDL)</b>
ModelSim PE/SE	Yes	Yes	Yes
ModelSim Altera Edition	Yes	Yes	No
Synopsys VCS	Yes <sup>(1)</sup>	Yes	No
Synopsys VCS-MX	Yes <sup>(1)</sup>	Yes	Yes
Cadence NC-Sim	Yes <sup>(1)</sup>	Yes	Yes
Aldec	Yes	Yes	Yes

**Note to Table 5–1:**

- (1) If the simulator is run on UNIX or Linux platforms, the Quartus II software must be running on the same platform to launch the simulator tool.

### Specify the Path for the Third-Party Simulator

To launch the third-party simulation tool, the absolute path for the selected simulator must be provided in the **Options** page under the Tools menu. See [Figure 5-4](#). Double click the **Location of executable** field to change or specify the absolute path.

**Figure 5-4. Specifying the Simulator Path**

### Specify the Testbench Settings

Specify the applicable testbench settings as follows:

1. Under the NativeLink Settings in the **Settings** dialog box ([Figure 5-3](#)), select the **Compile Test Bench** radio button and click **Test Benches** to display the **Test Benches** dialog box. See [Figure 5-5](#).

**Figure 5–5. Test Bench Dialog Box**

2. Click **New** to display the **New Test Bench Settings** dialog box (shown in [Figure 5–6](#)).

**Figure 5–6. New Test Bench Settings Dialog Box**

3. In the **New Test Bench Settings** dialog box, set the appropriate fields with the names for the testbenches.

For specific instructions about specifying testbench settings for your MegaCore function, refer to your MegaCore function user guide.

4. After specifying the testbench files, close the **New Test Bench Settings**, **Test Benches**, and **Settings** dialog boxes.

### *Analyze and Elaborate the Quartus II Project*

Before starting the simulation using the NativeLink feature, make sure that each IP megafunctions' variation files are included in your design project. On the Quartus II Processing menu, point to Start, then click **Start Analysis & Elaboration**.

### *Run RTL Functional Simulation*

After the design is analyzed and elaborated, you can start the simulation by clicking **Run EDA-RTL Simulation** from the Tools menu. See [Figure 5-7](#). During RTL functional simulation, the IPFS models are compiled and used by the simulator.

**Figure 5-7. Running Functional Simulation for IP using NativeLink**

## Simulating Altera IP Without the Quartus II NativeLink Feature

You can also simulate Altera IP directly with third-party simulators. If your design instantiates an IP megafunction, add its variation file to your simulation project. If the IP megafunction requires IPFS model files, **do not** add the megafunctions' variation file to your simulation project. Rather, add its' IPFS model files (either Verilog or VHDL) to your simulation project. The IPFS model generated by the Quartus II software instantiates high-level primitives such as adders, multipliers, and multiplexers, as well as the library of parameterized modules (LPM) functions and Altera megafunctions.

To properly compile, load, and simulate the IP megafunctions, you must first compile the following libraries in your simulation tool:

- **sgate**—includes the definition of the high-level primitives (needed for IPFS models)
- **altera\_mf**—includes the definition of Altera megafunctions
- **220model**—includes the definition of LPM functions

You can use these library files with any Altera-supported simulation tool. If you are using the ModelSim® Altera software, the libraries are precompiled and mapped.

To simulate a design containing a Nios® processor or Avalon® peripherals, refer to *AN 189 Simulating Nios Embedded Processor Designs*.

Table 5–2 lists the simulation library files, where *<path>* is the directory where the Quartus II software is installed.

<b>Location</b>	<b>HDL Language</b>	<b>Description</b>
<i>&lt;path&gt;/eda/sim_lib/sgate.v</i>	Verilog HDL	Libraries that contain simulation models for IP functional models
<i>&lt;path&gt;/eda/sim_lib/sgate.vhd</i>	VHDL	
<i>&lt;path&gt;/eda/sim_lib/sgate_pack.vhd</i>	VHDL	Libraries that contain VHDL component declarations for the <b>sgate.vhd</b> library
<i>&lt;path&gt;/eda/sim_lib/220model.v</i>	Verilog HDL	Libraries that contain simulation models for the Altera LPM version 2.2.0
<i>&lt;path&gt;/eda/sim_lib/220model.vhd</i>	VHDL	
<i>&lt;path&gt;/eda/sim_lib/220pack.vhd</i>	VHDL	Libraries that contain VHDL component declarations for the <b>220model.vhd</b> library
<i>&lt;path&gt;/eda/sim_lib/altera_mf.v</i>	Verilog HDL	Libraries that contain simulation models for Altera-specific megafunctions
<i>&lt;path&gt;/eda/sim_lib/altera_mf.vhd</i>	VHDL	
<i>&lt;path&gt;/eda/sim_lib/altera_mf_components.vhd</i>	VHDL	Libraries that contain VHDL component declarations for the <b>altera_mf.vhd</b> library

## Design Language Examples

The following design language examples explain how to simulate IP megafunctions directly with third-party simulator tools. These design examples describe simulation with:

- ModelSim Verilog
- ModelSim VHDL
- NC-VHDL
- VCS

### Verilog HDL Example: Simulating the IPFS Model in the ModelSim Software

The following example shows the process of simulating a Verilog HDL-based megafunction. The example assumes that the megafunction variation and the IPFS model are generated.

1. Create a ModelSim project by performing the following steps:
  - a. In the ModelSim software, on the File menu, point to New and click **Project**. The **Create Project** dialog box is shown.
  - b. Specify the name of your simulation project.
  - c. Specify the desired location for your simulation project.
  - d. Specify the default library name and click **OK**.
  - e. Add relevant files to your simulation project:
    - Your design files
    - The IPFS model generated by the Quartus II software (if you are using the ModelSim-Altera software, skip to step 5)
    - The **sgate.v**, **220model.v**, and **altera\_mf.v** library files
2. Create the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vlib sgate ←
```

```
vlib lpm ←
```

```
vlib altera_mf ←
```

3. Map to the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vmap sgate sgate ←
```

```
vmap lpm lpm ←
```

```
vmap altera_mf altera_mf ←
```

4. Compile the HDL into libraries by typing the following commands at the ModelSim prompt:

```
vlog -work altera_mf altera_mf.v ←
```

```
vlog -work sgate sgate.v ←
```

```
vlog -work lpm 220model.v ←
```

5. Compile the IPFS model by typing the following command at the ModelSim prompt:

```
vlog -work work <my_IP>.vo ←
```

6. Compile your RTL by typing the following command at the ModelSim prompt:

```
vlog -work work <my_design>.v ←
```

7. Compile the testbench by typing the following command at the ModelSim prompt:

```
vlog -work work <my_testbench>.v ←
```

8. Load the testbench by typing the following command at the ModelSim prompt:

```
vsim -L <altera_mf_library_path> -L <lpm_library_path>  
-L <sgate_library_path> work.<my_testbench> ←
```

### **VHDL Example: Simulating the IPFS Model in the ModelSim Software**

The following example shows the process of performing a functional simulation of a VHDL-based, megafunction IPFS model. The example assumes that the megafunction's variation and the IPFS model are generated.

1. Create a ModelSim project by performing the following steps:
  - a. In the ModelSim software, on the File menu, point to New and click **Project**. The **Create Project** dialog box appears.
  - b. Specify the name for your simulation project.
  - c. Specify the desired location for your simulation project.
  - d. Specify the default library name and click **OK**.
  - e. Add the relevant files to your simulation project:
    - Add your design files
    - Add the IPFS model generated by the Quartus II software (if you are using the ModelSim-Altera software, skip to step 5)
    - Add the **sgate.vhd**, **sgate\_pack.vhd**, **220model.vhd**, **220pack.vhd**, **altera\_mf.vhd**, and **altera\_mf\_components.vhd** library files

2. Create the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vlib sgate ←
```

```
vlib lpm ←
```

```
vlib altera_mf ←
```

3. Map to the required simulation libraries by typing the following commands at the ModelSim prompt:

```
vmap sgate sgate ←
```

```
vmap lpm lpm ←
```

```
vmap altera_mf altera_mf ←
```

4. Compile the HDL into libraries by typing the following commands at the ModelSim prompt:

```
vcom -work altera_mf -93 -explicit  
altera_mf_components.vhd ←
```

```
vcom -work altera_mf -93 -explicit altera_mf.vhd ←
```

```
vcom -work lpm -93 -explicit 220pack.vhd ↵
```

```
vcom -work lpm -93 -explicit 220model.vhd ↵
```

```
vcom -work sgate -93 -explicit sgate_pack.vhd ↵
```

```
vcom -work sgate -93 -explicit sgate.vhd ↵
```

5. Compile the IPFS model by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <output_netlist>.vho ↵
```

6. Compile the RTL by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <RTL>.vhd ↵
```

7. Compile the testbench by typing the following command at the ModelSim prompt:

```
vcom -work work -93 -explicit <my_testbench>.vhd ↵
```

8. Load the testbench by typing the following command at the ModelSim prompt:

```
vsim work.my_testbench ↵
```

## NC-VHDL Example: Simulating the IPFS Model in the NC-VHDL Software

The following example shows the process of performing a functional simulation of an NC-VHDL-based, megafunction IP functional-simulation model. The example assumes that the megafunction's variation and the IPFS model are generated.

1. Create a **cds.lib** file by typing the following entries:

```
DEFINE worklib ./worklib
```

```
DEFINE sgate ./sgate
```

```
DEFINE altera_mf ./altera_mf
```

```
DEFINE lpm ./lpm
```

2. Compile library files into appropriate libraries by typing the following commands at the command prompt:

```
ncvhdl -V93 -WORK lpm 220pack.vhd ↵
```

```
ncvhdl -V93 -WORK lpm 220model.vhd ↵
```

```
ncvhdl -V93 -WORK altera_mf  
altera_mf_components.vhd ↵
```

```
rncvhdl -V93 -WORK altera_mf altera_mf.vhd ↵
```

```
ncvhdl -V93 -WORK sgate sgate_pack.vhd ↵
```

```
ncvhdl -V93 -WORK sgate sgate.vhd ↵
```

3. Compile source code and testbench files by typing the following commands at the command prompt:

```
ncvhdl -V93 -WORK worklib <my_design>.vhd ↵
```

```
ncvhdl -V93 -WORK worklib <my_testbench>.vhd ↵
```

```
ncvhdl -V93 -WORK worklib  
<my_IPtoolbench_output_netlist>.vho ↵
```

4. Elaborate the design by typing the following command at the command prompt:

```
ncelab worklib.<my_testbench>.entity ↵
```

### Verilog HDL Example: Simulating Your IPFS Model in VCS

The following example illustrates the process of performing a functional simulation of a design that contains a Verilog HDL-based, megafunction IPFS model. This example assumes that the megafunction variation and the IPFS model are generated.

#### *Single-Step Process*

For the single-step process, type the following at the command prompt:

```
vcs <testbench>.v <RTL>.v <output_netlist>.v -v 220model.v  
altera_mf.v sgate.v -R ↵
```

### *Two-Step Process (Compilation and Simulation)*

For compilation and simulation, perform the following steps:

1. Compile your design files by typing the following at the command prompt:

```
vcs <testbench>.v <RTL>.v <output_netlist>.v -v 220model.v  
altera_mf.v sgate.v -o simulation_out ◀
```

2. Load your simulation by typing the following at a command prompt:

```
source simulation_out ◀
```

For more information about simulating a design in VCS, refer to the chapter *Synopsys VCS Support* in volume 3 of the *Quartus II Handbook*.

## Conclusion

Altera Quartus II software provides full support for simulating IP megafunction's with third party tools either directly or using its NativeLink feature. Using the Quartus II software, you can also generate IPFS models for supported megafunctions that enhances and simplifies design verification. Using an IPFS model is transparent, requiring only the addition of different files in which to synthesize and simulate projects.

As designs become more complex, the need for advanced timing analysis capability grows. Static timing analysis is a method of analyzing, debugging, and validating the timing performance of a design. The Quartus® II software provides the features necessary to perform advanced timing analysis for today's system-on-a-programmable-chip (SOPC) designs.

Synopsys PrimeTime is an industry standard sign-off tool, used to perform static timing analysis on most ASIC designs. The Quartus II software provides a path to enable you to run PrimeTime on your Quartus II software designs, and export a netlist, timing constraints, and libraries to the PrimeTime environment.

This section explains the basic principles of static timing analysis, the advanced features supported by the Quartus II Timing Analyzer, and how you can run PrimeTime on your Quartus designs.

This section includes the following chapters:

- [Chapter 6, The Quartus II TimeQuest Timing Analyzer](#)
- [Chapter 7, Switching to the Quartus II TimeQuest Timing Analyzer](#)
- [Chapter 8, Quartus II Classic Timing Analyzer](#)
- [Chapter 9, Synopsys PrimeTime Support](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

### Introduction

The Quartus® II TimeQuest Timing Analyzer is a powerful ASIC-style timing analysis tool that validates the timing performance of all logic in your design using an industry-standard constraint, analysis, and reporting methodology. Use the Quartus II TimeQuest Timing Analyzer's GUI or command-line interface to constrain, analyze, and report results for all timing paths in your design.

Before running the Quartus II TimeQuest Timing Analyzer, you must specify initial timing constraints that describe the clock characteristics, timing exceptions, and signal transition arrival and required times. You can specify timing constraints in the Synopsys Design Constraints (SDC) file format using the GUI or command-line interface. The Quartus II Fitter optimizes the placement of logic to meet your constraints.

During timing analysis, the Quartus II TimeQuest Timing Analyzer analyzes the timing paths in the design, calculates the propagation delay along each path, checks for timing constraint violations, and reports timing results as slack in the **Report** pane and in the **Console** pane. If the Quartus II TimeQuest Timing Analyzer reports any timing violations, you can customize the reporting to view precise timing information about specific paths, and then constrain those paths to correct the violations. When your design is free of timing violations, you can be confident that the logic will operate as intended in the target device.

the Quartus II TimeQuest Timing Analyzer is a complete static timing analysis tool that you can use as a sign-off tool for Altera® FPGAs and structured ASICs.

## Getting Started with the Quartus II TimeQuest Timing Analyzer

The Quartus II TimeQuest Timing Analyzer caters to the needs of the most basic to the most advanced designs for FPGAs.

This section provides a brief overview of the Quartus II TimeQuest Timing Analyzer, including the necessary steps to properly constrain a design, perform a full place-and-route, and perform reporting on the design.

### Setting Up the Quartus II TimeQuest Timing Analyzer

The Quartus II software version 7.2 supports two native timing analysis tools: Quartus II TimeQuest Timing Analyzer and the Quartus II Classic Timing Analyzer. When you specify the Quartus II TimeQuest Timing Analyzer as the default timing analysis tool, the Quartus II TimeQuest Timing Analyzer guides the Fitter and analyzes timing results after compilation.

To specify the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, on the Assignments menu, click **Settings**. In the **Settings** dialog box, in the **Category** list, select **Timing Analysis Settings**, and turn on **Use TimeQuest Timing Analyzer during compilation**.

To add the TimeQuest icon to the Quartus II toolbar, on the Tools menu, click **Customize**. In the **Customize** dialog box, click the **Toolbars** tab, turn on **Processing**, and click **Close**.

## Compilation Flow with the Quartus II TimeQuest Timing Analyzer Guidelines

When you enable the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, everything from constraint validation to timing verification is performed by the Quartus II TimeQuest Timing Analyzer. [Figure 6–1](#) shows the recommended design flow steps to maximize and leverage the benefits the Quartus II TimeQuest Timing Analyzer. Details about each step are provided after the figure.

*Figure 6–1. Design Flow with the Quartus II TimeQuest Timing Analyzer*

- **Create Quartus II Project and Specify Design Files**—Creates a project before you can compile design files. In this step you specify the target FPGA, any EDA tools used in the design cycle, and all design files.

You can also modify existing design files for design optimization and add additional design files. For example, you can add HDL files or schematics to the project.

- **Perform Initial Compilation**—Creates an initial design database before you specify timing constraints for your design. Perform Analysis and Synthesis to create a post-map database, or perform a full compilation to create a post-fit database.

Creating a post-map database for the initial compilation is faster than creating a post-fit database, and a post-map database is sufficient for the initial database.

Creating a post-fit database is recommended only if you previously created and specified an SDC file for the project. A post-map database is sufficient for the initial compilation.

- **Specify Design Requirements**—Timing requirements guide the Fitter as it places and routes your design.

You must enter all timing constraints and exceptions in an SDC file. This file must be included as part of the project. To add this file to your project, on the Project menu, click **Add/Remove Files in Project**, and add the SDC file in the **Files** dialog box.

Refer to “[Specify Timing Constraints](#)” on page 6–20 for a list of timing constraints and exceptions.

- **Perform Compilation**—Synthesizes, places, and routes your design into the target FPGA.

When compilation is complete, the TimeQuest Timing Analyzer generates summary clock setup and clock hold, recovery, and removal reports for all defined clocks in the design.

- **Verify Timing**—Verifies timing in your design with the Quartus II TimeQuest Timing Analyzer

## Running the Quartus II TimeQuest Timing Analyzer

You can run the Quartus II TimeQuest Timing Analyzer in one of the following modes:

- Directly from the Quartus II software
- Stand-alone mode
- Command-line mode

This section describes each of the modes, and the behavior of the Quartus II TimeQuest Timing Analyzer.

### *Directly from the Quartus II Software*

To run the Quartus II TimeQuest Timing Analyzer from the Quartus II software, on the Tools menu, click **TimeQuest Timing Analyzer**. The Quartus II TimeQuest Timing Analyzer is available after you have created a database for the current project. The database can be either a post-map or post-fit database; perform Analysis and Synthesis to create a post-map database, or a full compilation to create a post-fit database.

After a database is created in the Quartus II software, you can create a timing netlist based on that database. If you create a post-map database, you cannot create a post-fit timing netlist in the Quartus II TimeQuest Timing Analyzer.

When you launch the TimeQuest Timing Analyzer directly from the Quartus II software, the current project opens by default.

### Stand-Alone Mode

To run the Quartus II TimeQuest Timing Analyzer in stand-alone mode, type the following command at the command prompt:

```
quartus_staw ↵
```

In stand-alone mode, you can perform static analysis on any project that contains either a post-map or post-fit database. To open a project, double-click **Open Project** in the **Tasks** pane.

### Command-Line Mode

Use the command-line mode for easy integration with scripted design flows. Using the command-line mode avoids interaction with the user interface provided by the Quartus II TimeQuest Timing Analyzer, but allows the automation of each step of the static timing analysis flow.

Table 6-1 provides a summary of the options available in the command-line mode.

**Table 6-1. Summary of Command Line Options (Part 1 of 2)**

Command Line Option	Description
-h   --help	Provides help information on <code>quartus_sta</code> .
-t <script file>   --script=<script file>	Sources the <script file>.
-s   --shell	Enters shell mode.
--tcl_eval <tcl command>	Evaluates the Tcl command <tcl command>.
--do_report_timing	Runs the command: <code>report_timing -npaths 1 -to_clock \$clock</code> for all clocks in the design.
--force_dat	Forces the Delay Annotator to annotate the new delays from the recently compiled design to the compiler database.
--lower_priority	Lowers the computing priority of the <code>quartus_sta</code> process.
--post_map	Uses the post-map database results.
--qsf2sdc	Converts assignments from the Quartus II Settings File (.qsf) format to the Synopsys Design Constraints File format.
--sdc=<SDC file>	Specifies the SDC file to read.
--fast_model	Uses the fast corner delay models.
--report_script=<script>	Specifies a custom report script to be called.
--speed=<value>	Specifies the device speed grade to be used for timing analysis.

**Table 6–1. Summary of Command Line Options (Part 2 of 2)**

Command Line Option	Description
--tq2hc	Generate temporary files to convert the Quartus II TimeQuest Timing Analyzer SDC file(s) to a PrimeTime SDC file that can be used by the HardCopy Design Center (HCDC).
--tq2pt	Generate temporary files to convert the Quartus II TimeQuest Timing Analyzer SDC file(s) to a PrimeTime SDC file.
-f <argument file>	Specifies a file containing additional command-line arguments.
-c <revision name>   --rev=<revision_name>	Specifies which revision and its associated Quartus II Settings File (.qsf) to use.
--multicorner	Specifies that all slack summary reports be generated for both the slow and fast corners.

To run the Quartus II TimeQuest Timing Analyzer in command-line mode, type the following command at the command prompt:

```
quartus_sta <options> ↵
```

## Timing Analysis Overview

This section provides an overview of the Quartus II TimeQuest Timing Analyzer concepts. Understanding these concepts allows you to take advantage of the powerful timing analysis features available in the Quartus II TimeQuest Timing Analyzer.

the Quartus II TimeQuest Timing Analyzer follows the flow shown in [Figure 6-2](#) when it analyzes your design. [Table 6-2](#) lists the most commonly used commands for each step.

**Figure 6-2. The the Quartus II TimeQuest Timing Analyzer Flow**

Table 6–2 describes the Quartus II TimeQuest Timing Analyzer terminology.

<b>Table 6–2. The Quartus II TimeQuest Timing Analyzer Terms</b>	
<b>Terminology</b>	<b>Definition</b>
Nodes	Most basic timing netlist unit. Use to represent ports, pins, registers, and keepers.
Keepers	Ports or registers. (1)
Cells	Look-up table (LUT), registers, DSP blocks, TriMatrix® memory, IOE, and so on. (2)
Pins	Inputs or outputs of cells.
Nets	Connections between pins.
Ports	Top-level module inputs or outputs; for example, device pins.
Clocks	Abstract objects outside of the design.

**Notes to Table 6–2:**

- (1) Pins can indirectly refer to keepers. For example, when the value in the `-from` field of a constraint is a clock pin to a dedicated memory. In this case, the clock pin refers to a collection of registers.
- (2) For Stratix® devices and other early device families, the LUT and registers are contained in logic elements (LE) and act as cells for these device families.

The Quartus II TimeQuest Timing Analyzer requires a timing netlist before it can perform a timing analysis on any design. For example, for the design shown in Figure 6–3, the Quartus II TimeQuest Timing Analyzer generates a netlist equivalent to the one shown in Figure 6–4.

**Figure 6–3. Sample Design**

Figure 6–4. The Quartus II TimeQuest Timing Analyzer Timing Netlist

Figure 6–4 shows various cells, pins, nets, and ports. Sample cell names are `reg1`, `reg2`, and `and_inst`; sample pins are `data1 | combout`, `reg1 | regout`, and `and_inst | combout`; sample net names are `data1~combout`, `reg1`, and `and_inst`; and sample port names are `data1`, `clk`, and `data_out`.

Paths connect two design nodes, such as the output of a register to the input of another register. Timing paths play a significant role in timing analysis. Understanding the types of timing paths is important to timing closure and optimization. The following list shows some of the commonly analyzed paths that are described in this section:

- **Edges**—the connections from ports-to-pins, from pins-to-pins, and from pins-to-ports.
- **Clock paths**—the edges from device ports or internally generated clock pins to the clock pin of a register.
- **Data paths**—the edges from a port or the data output pin of a sequential element to a port or the data input pin of another sequential element.
- **Asynchronous paths**—the edges from a port or sequential element to the asynchronous set or clear pin of a sequential element.

Figure 6–5 shows some of these commonly analyzed path types.

**Figure 6-5. Path Types**

Once the Quartus II TimeQuest Timing Analyzer identifies the path type, it can report data and clock arrival times for valid register-to-register paths. The Quartus II TimeQuest Timing Analyzer calculates data arrival time by adding the delay from the clock source to the clock pin of the source register, the micro clock-to-out ( $\mu t_{CO}$ ) of the source register, and the delay from the source register's *Q* pin to the destination register's *D* pin, where the  $\mu t_{CO}$  is the intrinsic clock-to-out for the internal registers in the FPGA. The Quartus II TimeQuest Timing Analyzer calculates clock arrival time by adding the delay from the clock source to the destination register's clock pin. Figure 6-6 shows a data arrival path and a clock arrival path. The Quartus II TimeQuest Timing Analyzer calculates data required time by accounting for the clock arrival time and the micro setup time ( $\mu t_{SU}$ ) of the destination register, where the  $\mu t_{SU}$  is the intrinsic setup for the internal registers in the FPGA.

**Figure 6-6. Data Arrival and Clock Arrival**

In addition to identifying various paths in a design, the Quartus II TimeQuest Timing Analyzer analyzes clock characteristics to compute the worst-case requirement between any two registers in a single register-to-register path. You should constrain all clocks in your design before performing this analysis.

The launch edge is an active clock edge that sends data out of a sequential element, acting as a source for the data transfer. A latch edge is the active clock edge that captures data at the data port of a sequential element, acting as a destination for the data transfer.

Figure 6–7 shows a single-cycle system that uses consecutive clock edges to transfer and capture data, a register-to-register path, and the corresponding launch and latch edges timing diagram. In this example, the launch edge sends the data out of register `reg1` at 0 ns, and register `reg2` latch edge captures the data at 5 ns.

**Figure 6–7. Launch Edge and Latch Edge**

The Quartus II TimeQuest Timing Analyzer validates clock setup and hold requirements relative to the launch and latch edges.

## Clock Analysis

A comprehensive static timing analysis includes analysis of register-to-register, I/O, and asynchronous reset paths. The Quartus II TimeQuest Timing Analyzer uses data required times, data arrival times, and clock arrival times to verify circuit performance and detect possible timing violations. The Quartus II TimeQuest Timing Analyzer determines the timing relationships that must be met for the design to correctly function, and checks arrival times against required times to verify timing.

### Clock Setup Check

To perform a clock setup check, the Quartus II TimeQuest Timing Analyzer determines a setup relationship by analyzing each launch and latch edge for each register-to-register path. For each latch edge at the destination register, the Quartus II TimeQuest Timing Analyzer uses the closest previous clock edge at the source register as the launch edge. In

Figure 6–8, two setup relationships are defined and are labeled Setup A and Setup B. For the latch edge at 10 ns, the closest clock that acts as a launch edge is at 3 ns and is labeled Setup A. For the latch edge at 20 ns, the closest clock that acts as a launch edge is 19 ns, and is labeled Setup B.

**Figure 6–8. Setup Check**

The Quartus II TimeQuest Timing Analyzer reports the result of clock setup checks as slack values. Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met, and negative slack indicates the margin by which a requirement is not met. The Quartus II TimeQuest Timing Analyzer determines clock setup slack, as shown in Equation 1, for internal register-to-register paths.

$$(1) \quad \text{Clock Setup Slack} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{C0} + \text{Register-to-Register Delay}$$

$$\text{Data Required} = \text{Clock Arrival Time} - \mu t_{SU} - \text{Setup Uncertainty}$$

$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register}$$

If the data path is from an input port to an internal register, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 2 to calculate the setup slack time.

$$(2) \quad \text{Clock Setup Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Maximum Delay of Pin} + \text{Pin-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}$$

If the data path is an internal register to an output port, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 3 to calculate the setup slack time.

$$(3) \quad \text{Clock Setup Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Pin Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay} - \text{Output Maximum Delay of Pin}$$

### Clock Hold Check

To perform a clock hold check, the Quartus II TimeQuest Timing Analyzer determines a hold relationship for each possible setup relationship that exists for all source and destination register pairs. The Quartus II TimeQuest Timing Analyzer checks all adjacent clock edges from all setup relationships to determine the hold relationships. The Quartus II TimeQuest Timing Analyzer performs two hold checks for each setup relationship. The first hold check determines that the data launched by the current launch edge is not captured by the previous latch edge. The second hold check determines that the data launched by the next launch edge is not captured by the current latch edge. Figure 6–9 shows two setup relationships labeled setup A and setup B. The first hold check is labeled hold check A1 and hold check B1 for setup A and setup B, respectively. The second hold check is labeled hold check A2 and hold check B2 for setup A and setup B, respectively.

**Figure 6–9. Hold Checks**

From the possible hold relationships, The Quartus II TimeQuest Timing Analyzer selects the hold relationship that is the most restrictive. The hold relationship with the largest difference between the latch and launch edges (that is, latch – launch and not the absolute value of latch and

launch) is selected because this determines the minimum allowable delay for the register-to-register path. For Figure 6–9, the hold relationship selected is hold check A2.

The Quartus II TimeQuest Timing Analyzer determines clock hold slack as shown in Equation 4.

$$(4) \quad \text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$

$$\text{Data Required Time} = \text{Clock Arrival Time} + \mu t_H + \text{Hold Uncertainty}$$

$$\text{Clock Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register}$$

If the data path is from an input port to an internal register, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 5 to calculate the setup slack time.

$$(5) \quad \text{Clock Setup Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay of Pin} + \text{Pin-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_H$$

If the data path is an internal register to an output port, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 6 to calculate the setup slack time.

$$(6) \quad \text{Clock Setup Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Latch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Pin Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay} - \text{Output Minimum Delay of Pin}$$

### Recovery and Removal

Recovery time is the minimum length of time the de-assertion of an asynchronous control signal, for example, `clear` and `preset`, must be stable before the next active clock edge. The recovery slack time calculation is similar to the clock setup slack time calculation, but it applies to asynchronous control signals. If the asynchronous control signal is registered, the Quartus II TimeQuest Timing Analyzer uses Equation 7 to calculate the recovery slack time.

$$(7) \quad \text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} + \text{Register-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} - \mu t_{SU}$$

If the asynchronous control is not registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 8 to calculate the recovery slack time.

$$(8) \quad \text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Maximum Input Delay} + \text{Port-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register Delay} - \mu t_{SU}$$

If the asynchronous reset signal is from a port (device I/O), you must make an Input Maximum Delay assignment to the asynchronous reset port for the Quartus II TimeQuest Timing Analyzer to perform recovery analysis on that path.

Removal time is the minimum length of time the de-assertion of an asynchronous control signal must be stable after the active clock edge. The Quartus II TimeQuest Timing Analyzer removal time slack calculation is similar to the clock hold slack calculation, but it applies to asynchronous control signals. If the asynchronous control is registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in Equation 9 to calculate the removal slack time.

$$(9) \quad \text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay to Source Register} + \mu t_{CO} \text{ of Source Register} + \text{Register-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_H$$

If the asynchronous control is not registered, the Quartus II TimeQuest Timing Analyzer uses the equations shown in [Equation 10](#) to calculate the removal slack time.

$$(10) \quad \text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$\text{Data Arrival Time} = \text{Launch Edge} + \text{Clock Network Delay} + \text{Input Minimum Delay of Pin} + \text{Minimum Pin-to-Register Delay}$$

$$\text{Data Required Time} = \text{Latch Edge} + \text{Clock Network Delay to Destination Register} + \mu t_H$$

If the asynchronous reset signal is from a device pin, you must specify the Input Minimum Delay constraint to the asynchronous reset pin for the Quartus II TimeQuest Timing Analyzer to perform a removal analysis on this path.

### *Multicycle Paths*

Multicycle paths are data paths that require more than one clock cycle to latch data at the destination register. For example, a register may be required to capture data on every second or third rising clock edge.

[Figure 6-10](#) shows an example of a multicycle path between a multiplier's input registers and output register where the destination latches data on every other clock edge.

Figure 6–10. Example Diagram of a Multicycle Path

Figure 6–11 shows a register-to-register path where the source clock, `src_clk`, has a period of 10 ns and the destination clock, `dst_clk`, has a period of 5 ns.

Figure 6–11. Register-to-Register Path

Figure 6–12 shows the respective timing diagrams for the source and destination clocks and the default setup and hold relationships. The default setup relationship is 5 ns and the default hold relationship is 0 ns.

**Figure 6–12. Default Setup and Hold Timing Diagram**

The default setup and hold relationships can be modified with the `set_multicycle_path` command to accommodate the system requirements.

Table 6–3 shows the commands used to modify either the launch or latch edge times that the Quartus II TimeQuest Timing Analyzer Timing Analyzer uses to determine a setup relationship or hold relationship.

<b>Table 6–3. Commands to Modify Edge Times</b>	
<b>Command</b>	<b>Description of Modification</b>
<code>set_multicycle_path -setup -end</code>	Latch edge time of the setup relationship
<code>set_multicycle_path -setup -start</code>	Launch edge time of the setup relationship
<code>set_multicycle_path -hold -end</code>	Latch edge time of the hold relationship
<code>set_multicycle_path -hold -start</code>	Latch edge time of the hold relationship

Figure 6–13 shows the timing diagram after a multicycle setup of two has been applied. The command moves the latch edge time to 10 ns from the default 5 ns.

**Figure 6–13. Modified Setup Diagram**

## Specify Design Timing Requirements

Next, specify timing constraints and exceptions for your design.

Timing requirements guide the Fitter as it places and routes your design. You must enter all timing constraints and exceptions in an SDC file. This file must be included as part of the project. To add this file to your project, on the Project menu, click **Add/Remove Files in Project**, and add the SDC file in the **Files** dialog box.

 Refer to “Specify Timing Constraints” on page 6–20 for a list of timing constraints and exceptions.

After you create the initial database, follow these steps to create timing requirements:

1. Launch the Quartus II TimeQuest Timing Analyzer.
2. Create a Timing Netlist.
3. Specify Timing Constraints.
4. Generate SDC Constraint Reports.

 You cannot use the Assignment Editor to specify timing requirements for the TimeQuest timing analyzer.

### Create a Timing Netlist

The TimeQuest timing analyzer requires a timing netlist before you can specify timing requirements. The TimeQuest timing analyzer creates a timing netlist based upon the netlist generated in the compilation step. It annotates the timing netlist with either the post-map or post-fit delay results.

You can create a timing netlist in the following ways:

- In the **Tasks** pane, double-click **Create Timing Netlist**.

 By default, the **Create Timing Netlist** command generates a timing netlist based on the post-fit database. An error message displays if the initial database is a post-map database.

*or*

- On the Netlist menu, click **Create Timing Netlist**. The **Create Timing Netlist** dialog box appears (Figure 6–14).

**Figure 6–14. Create Timing Netlist Dialog Box**

In the **Create Timing Netlist** dialog box, specify the input netlist type and the delay model, and click **OK**.

or

- To create a timing netlist in the **Console** pane, type the following command at a Tcl prompt:

```
create_timing_netlist ←
```

You can use the `-post_map` option to specify that the timing netlist is based on a post-map database. For example, you can type the following command:

```
create_timing_netlist -post_map ←
```

## Specify Timing Constraints

Use the SDC Editor to create and edit your timing constraints and exceptions. The following constraints are available:

- Create Clock
- Create Generated Clock
- Set Clock Latency
- Set Clock Uncertainty
- Set Input Delay
- Set Output Delay
- Set False Path
- Set Multicycle Path
- Set Maximum Delay
- Set Minimum Delay

For more information on the SDC Editor, refer to “[SDC Editor](#)” on page 6–94.

The specified constraints and exceptions guide the Fitter as it places and routes your design. After you have specified all timing constraints and exceptions, save the SDC file.

## Generate SDC Constraint Reports

You can generate initial timing reports to verify that all constraints and exceptions have been entered. Because the constraints and exceptions have not been processed by the Fitter, do not use this step to verify that your timing requirements have been met.

You should verify the following items before continuing:

- All clocks are constrained
- Any invalid clock-to-clock transfers have been removed
- All paths are constrained

You can double-click the **Report Clocks** command in the **Tasks** pane, or type the `report_clocks` command in the **Console** pane to verify that all clocks have been properly defined and applied to the proper nodes in the design.

You can double-click the **Report Clock Transfers** command in the **Tasks** pane, or type the `report_clock_transfers` command in the **Console** pane to verify all clock-to-clock transfers.

You can double-click the **Report Unconstrained Paths** command in the **Tasks** pane, or type the `report_ucp` command in the **Console** pane to verify that all paths in the design have been properly constrained.

## The Quartus II TimeQuest Timing Analyzer Flow Guidelines

Use the steps shown in [Figure 6–15](#) to verify timing in the TimeQuest timing analyzer.

**Figure 6–15. Timing Verification in the TimeQuest Timing Analyzer**

The following sections describe each of the steps shown in [Figure 6–15](#).

### Create a Timing Netlist

After you perform a full compilation, you must create a timing netlist based on the fully annotated database from the post-fit results.

To create the timing netlist, double-click **Create Timing Netlist** in the **Tasks** pane, or type the following command in the **Console** pane:

```
create_timing_netlist ←
```

### Read the Synopsys Design Constraints File

After you create a timing netlist, you must read an SDC file. This step reads all constraints and exceptions defined in the SDC file.

You can read the SDC file from either the **Task** pane or the **Console** pane.

To read the SDC file from the **Tasks** pane, double-click the **Read SDC File** command.

 The **Read SDC File** task reads the `<current revision>.sdc` file.

To read the SDC file from the **Console** pane, type the following command in the **Console** pane:

```
read_sdc ←
```

## Update Timing Netlist

You must update the timing netlist after you read an SDC file. The TimeQuest timing analyzer applies all constraints to the netlist for verification, and removes any invalid or false paths in the design from verification.

To update the timing netlist, double-click **Update Timing Netlist** in the **Tasks** pane, or type the following command in the **Console** pane:

```
update_timing_netlist ←
```

## Generate Timing Reports

You can generate timing reports for all critical paths in your design. The **Tasks** pane contains the commonly used reporting commands. Individual or custom reports can be generated for your design.

For more information about reporting, refer to the section [“Timing Reports” on page 6–58](#).

For a full list of available report APIs, refer to the *SDC & TimeQuest API Reference Manual*.

As you verify timing, you may encounter failures along critical paths. If this occurs, you can refine the existing constraints or create new ones to change the effects of existing constraints. If you modify, remove, or add constraints, you should perform a full compilation. This allows the Fitter to re-optimize the design based upon the new constraints, and brings you back to the Perform Compilation step in the process. This iterative process allows you to resolve your timing violations in the design.

For a sample Tcl script to automate the timing analysis flow, refer to the *TimeQuest Quick Start Tutorial*.

## Collections

The Quartus II TimeQuest Timing Analyzer supports collection APIs that provide easy access to ports, pins, cells, or nodes in the design. Use collection APIs with any valid constraints or Tcl commands specified in the Quartus II TimeQuest Timing Analyzer.

Table 6–4 describes the collection commands supported by the Quartus II TimeQuest Timing Analyzer.

<b>Command</b>	<b>Description</b>
<code>all_clocks</code>	Returns a collection of all clocks in the design.
<code>all_inputs</code>	Returns a collection of all input ports in the design.
<code>all_outputs</code>	Returns a collection of all output ports in the design.
<code>all_registers</code>	Returns a collection of all registers in the design.
<code>get_cells</code>	Returns a collection of cells in the design. All cell names in the collection match the specified pattern. Wildcards can be used to select multiple cells at the same time.
<code>get_clocks</code>	Returns a collection of clocks in the design. When used as an argument to another command, such as the <code>-from</code> or <code>-to</code> of <code>set_multicycle_path</code> , each node in the clock represents all nodes clocked by the clocks in the collection. The default uses the specific node (even if it is a clock) as the target of a command.
<code>get_nets</code>	Returns a collection of nets in the design. All net names in the collection match the specified pattern. You can use wildcards to select multiple nets at the same time.
<code>get_pins</code>	Returns a collection of pins in the design. All pin names in the collection match the specified pattern. You can use wildcards to select multiple pins at the same time.
<code>get_ports</code>	Returns a collection of ports (design inputs and outputs) in the design.

Table 6–5 describes the SDC extension collection commands supported by the Quartus II TimeQuest Timing Analyzer.

<b>Command</b>	<b>Description</b>
<code>get_fanouts &lt;filter&gt;</code>	Returns a collection of fan-out nodes starting from <i>&lt;filter&gt;</i> .
<code>get_keepers &lt;filter&gt;</code>	Returns a collection of keeper nodes (non-combinational nodes) in the design.
<code>get_nodes &lt;filter&gt;</code>	Returns a collection of nodes in the design. The <code>get_nodes</code> collection cannot be used when specifying constraints or exceptions.
<code>get_partitions &lt;filter&gt;</code>	Returns a collection of partitions matching the <i>&lt;filter&gt;</i> .
<code>get_registers &lt;filter&gt;</code>	Returns a collection of registers in the design.
<code>get_fanins &lt;filter&gt;</code>	Returns a collection of fan-in nodes starting from <i>&lt;filter&gt;</i> .
<code>derive_pll_clocks</code>	Automatically create generated clocks on the outputs of PLL. The generated clock properties reflect the PLL properties that have been specified by the MegaWizard® Plug-In Manager.

**Table 6–5. SDC Extension Collection Commands (Part 2 of 2)**

Command	Description
<code>get_assignment_groups &lt;filter&gt;</code>	Returns either a collection of keepers, ports, or registers that have been saved to the Quartus Settings File (QSF) with the Assignment (Time) Groups option.
<code>remove_clock &lt;clock list&gt;</code>	Removes the list of clocks specified by <code>&lt;clock list&gt;</code> .
<code>set_scc_mode &lt;size&gt;</code>	Allows you to set the maximum Strongly Connected Components (SCC) loop size or force the Quartus II TimeQuest Timing Analyzer to always estimate delays through SCCs.
<code>set_time_format</code>	Sets time format, including time unit and decimal places.

For more information about collections, refer to the SDC file and the *SDC and TimeQuest API Reference Manual*.

### Application Examples

**Example 6–1** shows various uses of the `create_clock` and `create_generated_clock` commands and specific design structures.

#### **Example 6–1. create\_clock and create\_generate\_clock Commands and Specific Design Structures**

```
# Create a simple 10 ns with clock with a 60 % duty cycle
create_clock -period 10 -waveform {0 6} -name clk [get_ports clk]
# The following multicycle applies to all paths ending at registers
# clocked by clk
set_multicycle_path -to [get_clocks clk] 2
```

## Constraints Files

The Quartus II TimeQuest Timing Analyzer stores all timing constraints in an SDC file. You can create an SDC file with different constraints for place-and-route and for timing analysis.

The SDC file should contain only SDC and Tcl commands. Commands to manipulate the timing netlist or control the compilation flow should not be included in the SDC file.

The Quartus II software does not automatically update SDC files. You must explicitly write new or updated constraints in the TimeQuest GUI. Use the `write_sdc` command, or, in the Quartus II TimeQuest Timing Analyzer, on the Constraints menu, click **Write SDC File** to write your constraints to an SDC file.

## Fitter and Timing Analysis SDC Files

You can specify the same or different SDC files for the Quartus II Fitter for place-and-route, and the Quartus II TimeQuest Timing Analyzer for static timing analysis. Using different SDC files allows you to have one set of constraints for place-and-route, and another set of constraints for final timing sign-off in the Quartus II TimeQuest Timing Analyzer.

### *Specifying SDC Files for Place-and-Route*

To specify an SDC file for the Fitter, you must add the SDC file to your Quartus II project. To add the file to your project, use the following command in the Tcl console:

```
set_global_assignment -name SDC_FILE <SDC file name>
```

Or, in the Quartus II GUI, on the Project menu, click **Add/Remove Files in Project**.

The Fitter optimizes your design based on the requirements in the SDC files in your project.

The results shown in the timing analysis report located in the Compilation Report are based on the SDC files added to the project.

You must specify the Quartus II TimeQuest Timing Analyzer as the default timing analyzer to make the Fitter read the SDC file.

### *Specifying SDC Files for Static Timing Analysis*

After you create a timing netlist in the Quartus II TimeQuest Timing Analyzer, you must specify timing constraints and exceptions before you can perform a timing analysis. The timing requirements do not have to be identical to those provided to the Fitter. You can specify your timing requirements manually or you can read a previously created SDC file.

To manually enter your timing requirements, you can use constraint entry dialog boxes or SDC commands. If you have an SDC file that contains your timing requirements, you can use this file to apply your timing requirements. To specify the SDC file for timing analysis in the Quartus II TimeQuest Timing Analyzer, use the following command:

```
read_sdc [<SDC file name>]
```

If you use the TimeQuest GUI to apply SDC file for timing analysis, in the Quartus II TimeQuest Timing Analyzer, on the Constraints menu, click **Read SDC File**.

By default, the **Read SDC File** command in the **Tasks** pane reads the SDC files specified in the Quartus II Settings File (**.qsf**) (QSF), which are the same SDC files used by the Fitter.

## Synopsys Design Constraints File Precedence

The Quartus II Fitter and the Quartus II TimeQuest Timing Analyzer reads the SDC files from the files list in the QSF file in the order they are listed, from top to bottom.

The Quartus II software searches for an SDC file, as shown in [Figure 6–16](#).

**Figure 6–16. Synopsys Design Constraints File Order of Precedence**

**Note to [Figure 6–16](#):**

- (1) This occurs only in the Quartus II TimeQuest Timing Analyzer, and not during compilation in the Quartus II software. The Quartus II TimeQuest Timing Analyzer has the ability to automate the conversion of the QSF timing assignments to SDC if no SDC file exists when the Quartus II TimeQuest Timing Analyzer is opened.

If you type the `read_sdc` command at the command line without any arguments, the precedence order shown in [Figure 6–16](#) is followed.

## Clock Specification

The specification of all clocks and any associated clock characteristics in your design is essential for accurate static timing analysis results. The Quartus II TimeQuest Timing Analyzer supports many SDC commands that accommodate various clocking schemes and any clock characteristics.

This section describes the SDC file API available to create and specify clock characteristics.

### Clocks

Use the `create_clock` command to create a clock at any register, port, or pin. You can create each clock with unique characteristics. [Example 6–2](#) shows the `create_clock` command and options.

#### Example 6–2. `create_clock` Command

```
create_clock
-period <period value>
[-name <clock name>]
[-waveform <edge list>]
[-add]
<targets>
```

[Table 6–6](#) describes the options for the `create_clock` command.

Option	Description
<code>-period &lt;period value&gt;</code>	Specifies the clock period. You can also specify the clock period in units of frequency, such as <code>-period &lt;num&gt;MHz</code> . (1)
<code>-name &lt;clock name&gt;</code>	Name of the specific clock, for example, <code>sysclock</code> . If you do not specify the clock name, the clock name is the same as the node to which it is assigned.
<code>-waveform &lt;edge list&gt;</code>	Specifies the clock's rising and falling edges. The edge list alternates between rising edge and falling edge. For example, a 10 ns period where the first rising edge occurs at 0 ns and the first falling edge occurs at 5 ns would be written as <code>-waveform {0 5}</code> . The difference must be within one period unit, and the rise edge must come before the fall edge. The default edge list is <code>{0 &lt;period&gt;/2}</code> , or a 50% duty cycle.
<code>-add</code>	Allows you to specify more than one clock to the same port or pin.
<code>&lt;targets&gt;</code>	Specifies the port(s) or pin(s) to which the assignment applies. If source objects are not specified, the clock is a virtual clock. Refer to <a href="#">“Virtual Clocks” on page 6–32</a> for more information.

#### Note to [Table 6–6](#):

(1) The default time unit in the Quartus II TimeQuest Timing Analyzer is nanoseconds (ns).

Example 6–3 shows how to create a 10 ns clock with a 50% duty cycle, where the first rising edge occurs at 0 ns applied to port `clk`.

---

**Example 6–3. 100MHz Clock Creation**

```
create_clock -period 10 -waveform { 0 5 } clk
```

---

Example 6–4 shows how to create a 10 ns clock with a 50% duty cycle that is phase shifted by 90 degrees applied to port `clk_sys`.

---

**Example 6–4. 100MHz Shifted by 90 Degrees Clock Creation**

```
create_clock -period 10 -waveform { 2.5 7.5 } clk_sys
```

---

Clocks defined with the `create_clock` command have a default source latency value of zero. The Quartus II TimeQuest Timing Analyzer automatically computes the clock's network latency for non-virtual clocks.

## Generated Clocks

The Quartus II TimeQuest Timing Analyzer considers clock dividers, ripple clocks, or circuits that modify or change the characteristics of the incoming or master clock as generated clocks. You should define the output of these circuits as generated clocks. This definition allows the Quartus II TimeQuest Timing Analyzer to analyze these clocks and account for any network latency associated with them.

Use the `create_generated_clock` command to create generated clocks. Example 6–5 shows the `create_generated_clock` command and the available options.

---

**Example 6–5. create\_generated\_clock Command**

```
create_generated_clock
[-name <clock name>]
-source <master pin>
[-edges <edge list>]
[-edge_shift <shift list>]
[-divide_by <factor>]
[-multiply_by <factor>]
[-duty_cycle <percent>]
[-add]
[-invert]
[-master_clock <clock>]
[-phase <phase>]
[-offset <offset>]
<targets>
```

---

Table 6-7 describes the options for the `create_generated_clock` command.

<b>Table 6-7. create_generated_clock Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>-name &lt;clock name&gt;</code>	Name of the generated clock, for example, <code>clk_x2</code> . If you do not specify the clock name, the clock name is the same as the first node to which it is assigned.
<code>-source &lt;master pin&gt;</code>	The <code>&lt;master pin&gt;</code> specifies the node in the design from which the clock settings derive.
<code>-edges &lt;edge list&gt;   -edge_shift &lt;shift list&gt;</code>	<p>The <code>-edges</code> option specifies the new rising and falling edges with respect to the master clock's rising and falling edges. The master clock's rising and falling edges are numbered 1 . . . <code>&lt;n&gt;</code> starting with the first rising edge, for example, edge 1. The first falling edge after that is edge number 2, the next rising edge number 3, and so on. The <code>&lt;edge list&gt;</code> must be in ascending order. The same edge may be used for two entries to indicate a clock pulse independent of the original waveform's duty cycle.</p> <p><code>-edge_shift</code> specifies the amount of shift for each edge in the <code>&lt;edge list&gt;</code>. The <code>-invert</code> option can be used to invert the clock after the <code>-edges</code> and <code>-edge_shifts</code> are applied. (1)</p>
<code>-divide_by &lt;factor&gt;   -multiply_by &lt;factor&gt;</code>	The <code>-divide_by</code> and <code>-multiply_by</code> factors are based on the first rising edge of the clock, and extend or contract the waveform by the specified factors. For example, a <code>-divide_by 2</code> is equivalent to <code>-edges {1 3 5}</code> . For multiplied clocks, the duty cycle can also be specified. The Quartus II TimeQuest Timing Analyzer supports specifying multiply and divide factors at the same time.
<code>-duty_cycle &lt;percent&gt;</code>	Specifies the duty cycle of the generated clock. The duty cycle is applied last.
<code>-add</code>	Allows you to specify more than one clock to the same pin.
<code>-invert</code>	Inversion is applied at the output of the clock after all other modifications are applied, except duty cycle.
<code>-master_clock &lt;clock&gt;</code>	<code>-master_clock</code> is used to specify the clock if multiple clocks exist at the master pin.
<code>-phase &lt;phase&gt;</code>	Specifies the phase of the generated clock.
<code>-offset &lt;offset&gt;</code>	Specifies the offset of the generated clock.
<code>&lt;targets&gt;</code>	Specifies the port(s) or pin(s) to which the assignment applies.

**Note to Table 6-7:**

(1) The Quartus II TimeQuest Timing Analyzer supports a maximum of three edges in the edge list.

Source latencies are based on clock network delays from the master clock (not necessarily the master pin). You can use the `set_clock_latency -source` command to override the source latency.

Figure 6–17 shows how to create an inverted generated clock based on a 10 ns clock.

**Figure 6–17. Generating an Inverted Clock**

```
create_clock -period 10 [get_ports clk]
create_generated_clock -divide_by 1 -invert -source [get_registers clk] \
  [get_registers gen|clkreg]
```

Figure 6–18 shows how to modify the generated clock using the `-edges` and `-edge_shift` options.

**Figure 6–18. Edges and Edge Shifting a Generated Clock**

```
create_clock -period 10 -waveform { 0 5 } [get_ports clk]
# Creates a divide-by-t clock
create_generated_clock -source [get_ports clk] -edges {1 3 5 } [get_registers \
  clkdivA|clkreg]
# Creates a divide-by-2 clock independent of the master clocks' duty cycle (now 50%)
create_generated_clock -source [get_ports clk] -edges {1 1 5} -edge_shift { 0 2.5 0 } \
  [get_registers clkdivB|clkreg]
```

Figure 6–19 shows the effect of the `-multiply_by` option on the generated clock.

**Figure 6–19. Multiplying a Generated Clock**

```
create_clock -period 10 -waveform { 0 5 } [get_ports clk]
# Creates a multiply-by-2 clock
create_generated_clock -source [get_ports clk] -multiply_by 2 [get_registers \
clkmult|clkreg]
```

## Virtual Clocks

A virtual clock is a clock that does not have a real source in the design or that does not interact directly with the design. For example, if a clock feeds only an external device's clock port, and not a clock port in the design, and the external device then feeds (or is fed by) a port in the design, it is considered a virtual clock.

Use the `create_clock` command to create virtual clocks, with no value specified for the `source` option.

 You can use virtual clocks for `set_input_delay` and `set_output_delay` constraints.

Figure 6–20 shows an example where a virtual clock is required for the Quartus II TimeQuest Timing Analyzer to properly analyze the relationship between the external register and those in the design. Because the oscillator labeled `virt_clk` does not interact with the Altera device, but acts as the clock source for the external register, the clock `virt_clk` must be declared. Example 6–6 shows the command to create a 10 ns virtual clock named `virt_clk` with a 50% duty cycle where the first rising edge occurs at 0 ns. The virtual clock is then used as the clock source for an output delay constraint.

**Figure 6–20. Virtual Clock Board Topology**

After you create the virtual clock, you can perform register-to-register analysis between the register in the Altera device and the register in the external device.

**Example 6–6. Virtual Clock Example 1**

```
#create base clock for the design
create_clock -period 5 [get_ports system_clk]
#create the virtual clock for the external register
create_clock -period 10 -name virt_clk -waveform { 0 5 }
#set the output delay referencing the virtual clock
set_output_delay -clock virt_clk -max 1.5 [get_ports dataout]
```

Example 6–7 shows the command to create a 10 ns virtual clock with a 50% duty cycle that is phase shifted by 90 degrees.

**Example 6–7. Virtual Clock Example 2**

```
create_clock -name virt_clk -period 10 -waveform { 2.5 7.5 }
```

**Multi-Frequency Clocks**

Certain designs have more than one clock source feeding a single clock port in the design. The additional clock may act as a low power clock, with a lower frequency than the primary clock. To analyze this type of design, the `create_clock` command supports the `-add` option that allows you to add more than one clock to a clock node.

Example 6–8 shows the command to create a 10 ns clock applied to clock port `clk`, and then add an additional 15 ns clock to the same clock port. The Quartus II TimeQuest Timing Analyzer uses both clocks when it performs timing analysis.

**Example 6–8. Multi-Frequency Example**

```
create_clock -period 10 -name clock_primary -waveform { 0 5 } [get_ports clk]
create_clock -period 15 -name clock_secondary -waveform { 0 7.5 } [get_ports clk] -add
```

## Automatic Clock Detection

To create clocks for all clock nodes in your design automatically, use the `derive_clocks` command. This command creates clocks on ports or registers to ensure every register in the design has a clock.

Example 6-9 shows the `derive_clocks` command and options.

### Example 6-9. `derive_clocks` Command

```
derive_clocks
[-period <period value>]
[-waveform <edge list>]
```

Table 6-8 describes the options for the `derive_clocks` command.

Option	Description
<code>-period &lt;period value&gt;</code>	Creates the clock period. You can also specify the frequency as <code>-period &lt;num&gt;MHz</code> . (1)
<code>-waveform &lt;edge list&gt;</code>	Creates the clock's rising and falling edges. The edge list alternates between rising edge and falling edge. For example, for a 10 ns period where the first rising edge occurs at 0 ns and first falling edge occurs at 5 ns, the edge list is <code>waveform {0 5}</code> . The difference must be within one period unit, and the rising edge must come before the falling edge. The default edge list is <code>{0 period/2}</code> , or a 50% duty cycle.

**Note to Table 6-8:**

(1) This option uses the default time unit nanoseconds (ns).

The `derive_clocks` command does not create clocks for the outputs of the PLLs.

The `derive_clocks` command is equivalent to using `create_clock` for each register or port feeding the clock pin of a register.

The use of the `derive_clocks` command for final timing sign-off is not recommended. You should create clocks for all clock sources using the `create_clock` and `create_generated_clock` commands.

## Derive PLL Clocks

PLLs are used for clock management and synthesis in Altera devices. You can customize the clocks generated from the outputs of the PLL based on the design requirements. Because a clock should be created for all clock nodes, all outputs of the PLL should have an associated clock.

You can manually create a clock for each output of the PLL with the `create_generated_clock` command, or you can use the `derive_pll_clocks` command, which automatically searches the timing netlist and creates generated clocks for all PLL outputs according to the settings specified for each PLL output.

Use the `derive_pll_clocks` command to automatically create a clock for each output of the PLL, as shown in the following list:

```
derive_pll_clocks
[-use_tan_name]
```

Table 6-9 describes the options for the `derive_pll_clocks` command.

Option	Description
<code>-use_tan_name</code>	By default, the clock name is the output clock name. This option uses the net name similar to the names used by the Quartus II Classic Timing Analyzer.

The `derive_pll_clocks` command calls the `create_generated_clock` command to create generated clocks on the outputs of the PLL. The source for the `create_generated_clock` command is the input clock pin of the PLL. Before or after the `derive_pll_clocks` command has been issued, you must manually create a base clock for the input clock port of the PLL. If a clock is not defined for the input clock node of the PLL, no clocks are reported for the PLL outputs. Instead, the Quartus II TimeQuest Timing Analyzer issues a warning message similar to Figure 6-10 when the timing netlist is updated.

### **Example 6-10. Warning Message**

```
Warning: The master clock for this clock assignment could not be derived.
Clock: <name of PLL output clock pin name> was not created.
```

You can include the `derive_pll_clocks` command in your SDC file, which allows the `derive_pll_clocks` command to automatically detect any changes to the PLL. With the `derive_pll_clocks`

command in your SDC file, each time the file is read, the appropriate `create_generated_clock` command for the PLL output clock pin is generated. If you use the `write_sdc` command after the `derive_pll_clock` command, the new SDC file contains the individual `create_generated_clock` commands for the PLL output clock pins and not the `derive_pll_clocks` command. Any changes to the properties of the PLL are not automatically reflected in the new SDC file. You must manually update the `create_generated_clock` commands in the new SDC file written by the `derive_pll_clocks` command, to reflect the changes to the PLL.

 The `derive_pll_clocks` constraint will also constrain any LVDS transmitters or LVDS receivers in the design by adding the appropriate multicycle constraints to account for any deserialization factors.

For example, [Figure 6–21](#) shows a simple PLL design with a register-to-register path.

**Figure 6–21. Simple PLL Design**

Use the `derive_pll_clocks` command to automatically constrain the PLL. When this command is issued for the design shown in [Figure 6–21](#), the messages shown in [Example 6–11](#) are generated.

#### **Example 6–11. `derive_pll_clocks` Generated Messages**

```

Info:
Info: Deriving PLL Clocks:
Info: create_generated_clock -source pll_inst|altpll_component|pll|inclk[0] -divide_by 2 -name
pll_inst|altpll_component|pll|CLK[0] pll_inst|altpll_component|pll|clk[0]
Info:
  
```

The node name `pll_inst|altpll_component|pll|inclk[0]` used for the source option refers to the input clock pin of the PLL. In addition, the name of the output clock of the PLL is the name of the PLL output clock node, `pll_inst|altpll_component|pll|clk[0]`.

If the PLL is in clock switchover mode, multiple clocks are created for the output clock of the PLL; one for the primary input clock (for example, `inclk[0]`), and one for the secondary input clock (for example, `inclk[1]`). In this case, you should cut the primary and secondary output clocks using the `set_clock_groups` command with the `-exclusive` option.

Before you can generate any reports for this design, you must create a base clock for the PLL input clock port. Use a command similar to the following:

```
create_clock -period 5 [get_ports pll_inclk]
```

You do not have to generate the base clock on the input clock pin of the PLL: `pll_inst | altpll_component | pll | inclk[0]`. The clock created on the PLL input clock port propagates to all fan-outs of the clock port, including the PLL input clock pin.

## Default Clock Constraints

To provide a complete clock analysis, the Quartus II TimeQuest Timing Analyzer, by default, automatically creates clocks for all detected clock nodes in your design that have not been constrained, if there are no base clock constraints in the design. The Quartus II TimeQuest Timing Analyzer creates a base clock with a 1 GHz requirement to unconstrained clock nodes, using the following command:

```
derive_clocks -period 1
```

Individual clock constraints (for example, `create_clock`, `create_generated_clock`) should be made for all clocks in the design. This results in a thorough and realistic analysis of the design's timing requirements. The use of `derive_clocks` should be avoided for final timing sign-off.

The default clock constraint is only applied when the Quartus II TimeQuest Timing Analyzer detects that all synchronous elements have no clocks associated with them. For example, if a design contains two clocks and only one clock has constraints, the default clock constraint will not be applied. However, if both clocks have not been constrained, the default clock constraint will be applied.

## Clock Groups

Many clocks can exist in a design, however, not all of the clocks interact with one another, and certain clock interactions are not possible. Asynchronous clocks are unrelated clocks (asynchronous clocks have

different ideal clock sources). Exclusive clocks are not active at the same time (for example, multiplexed clocks). The mutual exclusivity must be declared to the Quartus II TimeQuest Timing Analyzer to prevent it from analyzing these clock interactions.

Use the `set_clock_groups` command to specify clocks that are exclusive or asynchronous. [Example 6–12](#) shows the `set_clock_groups` command and options.

---

**Example 6–12. `set_clock_groups` Command**

```
set_clock_groups
[-asynchronous | -exclusive]
-group <clock name>
[-group <clock name>]
[-group <clock name>] ...
```

---

[Table 6–10](#) describes the options for the `set_clock_groups` command.

Option	Description
-asynchronous	Asynchronous clocks—when the two clocks have no phase relationship and are active at the same time.
-exclusive	Exclusive clocks—when only one of the two clocks will be active at any given time. An example of an exclusive clock group is when two clocks feed a 2-to-1 MUX.
-group <clock name>	Specifies valid destination clock names that are mutually exclusive. <clock name> is used to specify the clock names.

[Example 6–13](#) shows a `set_clock_groups` command and the equivalent `set_false_path` commands.

---

**Example 6–13. `set_clock_groups` Example**

```
# Clocks A and C are never active when clocks B and D are active
set_clock_groups -exclusive -group {A C} -group {B D}

# Equivalent specification using false paths
set_false_path -from [get_clocks A] -to [get_clocks B]
set_false_path -from [get_clocks A] -to [get_clocks D]
set_false_path -from [get_clocks C] -to [get_clocks B]
set_false_path -from [get_clocks C] -to [get_clocks D]
set_false_path -from [get_clocks B] -to [get_clocks A]
set_false_path -from [get_clocks B] -to [get_clocks C]
set_false_path -from [get_clocks D] -to [get_clocks A]
set_false_path -from [get_clocks D] -to [get_clocks C]
```

---

## Clock Effect Characteristics

The `create_clock` and `create_generated_clock` commands create ideal clocks that do not account for any board effects. This section describes how to account for clock effect characteristics with clock latency and clock uncertainty.

### Clock Latency

There are two forms of clock latency: source and network. Source latency is the propagation delay from the origin of the clock to the clock definition point (for example, a clock port), and network latency is the propagation delay from a clock definition point to a register's clock pin. The total latency (or clock propagation delay) at a register's clock pin is the sum of the source and network latencies in the clock path.

 The `set_clock_latency` command supports only source latency. The `-source` option must be specified when using the command.

Use the `set_clock_latency` command to specify source latency to any clock ports in the design. [Example 6-14](#) shows the `set_clock_latency` command and options.

---

#### Example 6-14. `set_clock_latency` Command

```
set_clock_latency
-source
[-clock <clock_list>]
[-rise | -fall]
[-late | -early]
<delay>
<targets>
```

---

[Table 6-11](#) describes the options for the `set_clock_latency` command.

**Table 6-11. `set_clock_latency` Command Options (Part 1 of 2)**

Option	Description
<code>-source</code>	Specifies a source latency.
<code>-clock &lt;clock list&gt;</code>	Specifies the clock to use if the target has more than one clock assigned to it.

**Table 6–11. set\_clock\_latency Command Options (Part 2 of 2)**

Option	Description
-rise   -fall	Specifies the rising or falling delays.
-late   -early	Specifies the earliest or the latest arrival times to the clock.
<delay>	Specifies the delay value.
<targets>	Specifies the clocks or clock sources if a clock is clocked by more than one clock.

The Quartus II TimeQuest Timing Analyzer automatically computes network latencies; therefore, the `set_clock_latency` command specifies only the source latencies.

### *Clock Uncertainty*

The `set_clock_uncertainty` command specifies clock uncertainty or skew for clocks or clock-to-clock transfers. Specify the uncertainty separately for setup and hold, and you can specify separate rising and falling clock transitions. The Quartus II TimeQuest Timing Analyzer subtracts the setup uncertainty from the data required time for each applicable path, and adds the hold uncertainty to the data required time for each applicable path.

Use the `set_clock_uncertainty` command to specify any clock uncertainty to the clock port. [Example 6–15](#) shows the `set_clock_uncertainty` command and options.

---

### **Example 6–15. set\_clock\_uncertainty Command and Options**

```
set_clock_uncertainty
[-rise_from <rise from clock> | -fall_from <fall from clock> |
-from <from clock>]
[-rise_to <rise to clock> | -fall_to <fall to clock> | -to <to clock>]
[-setup | -hold]
<value>
```

---

Table 6–12 describes the options for the `set_clock_uncertainty` command.

Option	Description
<code>-from &lt;from clock&gt;</code>	Specifies the from clock.
<code>-rise_from &lt;rise from clock&gt;</code>	Specifies the rise from clock.
<code>-fall_from &lt;fall from clock&gt;</code>	Specifies the fall from clock.
<code>-to &lt;to clock&gt;</code>	Specifies the to clock.
<code>-rise_to &lt;rise to clock&gt;</code>	Specifies the rise to clock.
<code>-fall_to &lt;fall to clock&gt;</code>	Specifies the fall to clock.
<code>-setup   -hold</code>	Specifies setup or hold.
<code>&lt;value&gt;</code>	Uncertainty value.

## Derive Clock Uncertainty

Use the `derive_clock_uncertainty` command to automatically apply inter-clock, intra-clock, and I/O interface uncertainties. Both setup and hold uncertainties are calculated for each clock-to-clock transfer.

Example 6–16 shows the `derive_clock_uncertainty` command and options.

---

### **Example 6–16. `derive_clock_uncertainty` Command**

```
derive_clock_uncertainty
[-overwrite]
[-dtw]
```

---

Table 6–13 describes the options for the `derive_clock_uncertainty` command.

Option	Description
<code>-overwrite</code>	Overwrites previously performed clock uncertainty assignments
<code>-dtw</code>	Creates the <code>PLLJ-PLLSPE_INFO.txt</code> file

The Quartus II TimeQuest Timing Analyzer automatically applies clock uncertainties to clock-to-clock transfers in the design.

Any clock uncertainty constraints that have been applied to source and destination clock pairs with the `set_clock_uncertainty` command have a higher precedence than the clock uncertainties derived from the `derive_clock_uncertainty` command for the same source and destination clock pairs. For example, if the `set_clock_uncertainty` command is called first to specify clock uncertainties between the source clock `CLKA` and destination clock `CLKB`. Then the `derive_clock_uncertainty` command is called second, the clock uncertainty calculated by the `derive_clock_uncertainty` command is ignored for the source clock `CLKA` to destination clock `CLKB`.

The clock uncertainty value that would have been used, however, is still reported for informational purposes. You can use the `-overwrite` command to overwrite previous clock uncertainty assignments, or remove them manually with the `remove_clock_uncertainty` command.

In the following types of clock-to-clock transfers, clock certainties can arise. They are modeled by the `derive_clock_uncertainty` command automatically.

- Inter-clock
- Intra-clock
- I/O Interface

### *Inter-Clock Transfers*

Inter-clock transfers occur when the register-to-register transfer happens in the core of the FPGA and source and destination clocks come from the same PLL output pin or clock port. An example of an inter-clock transfer is shown in [Figure 6–22](#).

**Figure 6–22. Inter-Clock Transfer**

### Intra-Clock Transfers

Intra-clock transfers occur when the register-to-register transfer happens in the core of the FPGA and source and destination clocks come from a different PLL output pin or clock port. An example of an intra-clock transfer is shown in [Figure 6–23](#).

**Figure 6–23. Intra-Clock Transfer**

### I/O Interface Clock Transfers

I/O interface clock transfers occur when data transfers from an I/O port to the core of the FPGA (input) or from the core of the FPGA to the I/O port (output). An example of an I/O interface clock transfer is shown in [Figure 6–24](#).

**Figure 6–24. Interface-Clock Transfer**

For I/O interface uncertainty, you must create a virtual clock and constrain the input and output ports with the `set_input_delay` and `set_output_delay` commands that reference the virtual clock. The virtual clock is required to prevent the `derive_clock_uncertainty` command from applying clock certainties for either intra- or inter-clock transfers on an I/O interface clock transfer when the `set_input_delay` or `set_output_delay` commands reference a clock port or PLL output. If a virtual clock is not referenced in the `set_input_delay` or `set_output_delay` commands to clock uncertainty for the I/O interface clock, transfers will result in a pessimistic analysis.

The virtual clock should be created with the same properties as the original clock that is driving the I/O port. For example, [Figure 6–25](#) shows a typical input I/O interface with the clock specifications.

**Figure 6–25. I/O Interface Specifications**

[Example 6–17](#) shows the SDC commands to constrain the I/O Interface shown in [Figure 6–25](#).

**Example 6–17. SDC Commands to Constrain the I/O Interface**

```
# Create the base clock for the clock port
create_clock -period 10 -name clk_in [get_ports clk_in]
# Create a virtual clock with the same properties of the base clock driving
# the source register
create_clock -period 10 -name virt_clk_in
# Create the input delay referencing the virtual clock and not the base
# clock
# DO NOT use set_input_delay -clock clk_in <delay_value>
# [get_ports data_in]
set_input_delay -clock virt_clk_in <delay_value> [get_ports data_in]
```

## I/O Specifications

The Quartus II TimeQuest Timing Analyzer supports Synopsys Design Constraints that constrain the ports in your design. These constraints allow the Quartus II TimeQuest Timing Analyzer to perform a system static timing analysis that includes not only the FPGA timing, but also any external device timing and board timing parameters.

### Input and Output Delay

Use input and output delay constraints to specify any external device or board timing parameters. When you apply these constraints, the Quartus II TimeQuest Timing Analyzer performs static timing analysis on the entire system.

#### Set Input Delay

The `set_input_delay` constraint specifies the data arrival time at a port (a device I/O) with respect to a given clock. [Figure 6–26](#) shows an input delay path.

**Figure 6–26. Set Input Delay**

Use the `set_input_delay` command to specify input delay constraints to ports in the design. [Example 6–18](#) shows the `set_input_delay` command and options.

#### Example 6–18. `set_input_delay` Command

```
set_input_delay
-clock <clock name>
[-clock_fall]
[-rise | -fall]
[-max | -min]
[-add_delay]
[-reference_pin <target>]
[-source_latency_included]
<delay value>
<targets>
```

Table 6–14 describes the options for the `set_input_delay` command.

Option	Description
<code>-clock &lt;clock name&gt;</code>	Specifies the source clock.
<code>-clock_fall</code>	Specifies the arrival time with respect to the falling edge of the clock.
<code>-rise</code>   <code>-fall</code>	Specifies either the rise or fall delay at the port.
<code>-max</code>   <code>-min</code>	Specifies the minimum or maximum data arrival time.
<code>-add_delay</code>	Adds another delay, but does not replace the existing delays assigned to the port.
<code>-reference_pin &lt;target&gt;</code>	Specifies a pin or port in the design from which to determine source and network latencies. This is useful to specify input delays relative to an output port fed by a clock.
<code>-source_latency_included</code>	Specifies that the input delay value includes the source latency delay value, and therefore any source clock latency assigned to the clock will be ignored.
<code>&lt;delay value&gt;</code>	Specifies the delay value.
<code>&lt;targets&gt;</code>	Specifies the destination ports or pins.

A warning message appears if you specify only a `-max` or `-min` value for the input delay value. The input minimum delay default value is the input maximum delay, and the input maximum delay default value is the input minimum delay, if only one is specified. Similarly, a warning message appears if you specify only a `-rise` or `-fall` value for the delay value, and the delay defaults in the same manner as the input minimum and input maximum delays.

The maximum value is used for setup checks, and the minimum value is used for hold checks.

By default, a set of input delays (min/max, rise/fall) is allowed for only one clock, `-clock_fall`, `-reference_pin` combination. Specifying an input delay on the same port for a different clock, `-clock_fall`, or `-reference_pin` removes any previously set input delays, unless you specify the `-add_delay` option. When you specify the `-add_delay` option, the worst-case values are used.

The `-rise` and `-fall` options are mutually exclusive. The `-min` and `-max` options are also mutually exclusive.

### Set Output Delay

The `set_output_delay` command specifies the data required time at a port (the device pin) with respect to a given clock.

Use the `set_output_delay` command to specify output delay constraints to ports in the design. [Figure 6–27](#) shows an output delay path.

**Figure 6–27. Output Delay**

[Example 6–19](#) shows the `set_output_delay` command and options.

#### Example 6–19. `set_output_delay` Command

```
set_output_delay
-clock <clock name>
[-clock_fall]
[-rise | -fall]
[-max | -min]
[-add_delay]
[-reference_pin <target>]
<delay value>
<targets>
```

[Table 6–15](#) describes the options for the `set_output_delay` command.

<b>Table 6–15. <code>set_output_delay</code> Command Options (Part 1 of 2)</b>	
<b>Option</b>	<b>Description</b>
<code>-clock &lt;clock name&gt;</code>	Specifies the source clock.
<code>-clock_fall</code>	Specifies the required time with respect to the falling edge of the clock.
<code>-rise   -fall</code>	Specifies either the rise or fall delay at the port.
<code>-max   -min</code>	Specifies the minimum or maximum data arrival time.
<code>-add_delay</code>	Adds another delay, but does not replace the existing delays assigned to the port.

**Table 6–15. set\_output\_delay Command Options (Part 2 of 2)**

Option	Description
<code>-reference_pin &lt;target&gt;</code>	Specifies a pin or port in the design from which to determine source and network latencies. Use this option to specify input delays relative to an output port fed by a clock.
<code>-source_latency_included</code>	Specifies that the input delay value includes the source latency delay value, and therefore any source clock latency assigned to the clock will subsequently be ignored.
<code>&lt;delay value&gt;</code>	Specifies the delay value.
<code>&lt;targets&gt;</code>	Specifies the destination ports or pins.

A warning message appears if you specify only a `-max` or `-min` value for the output delay value. The output minimum delay default value is the output maximum delay, and the output maximum delay default value is the output minimum delay, if only one is specified.

The maximum value is used for setup checks, and the minimum value is used for hold checks.

By default, a set of output delays (min/max, rise/fall) is allowed for only one clock, `-clock_fall`, port combination. Specifying an output delay on the same port for a different clock or `-clock_fall` removes any previously set output delays, unless you specify the `-add_delay` option. When you specify the `-add_delay` option, the worst-case values are used.

The `-rise` and `-fall` options are mutually exclusive, as are the `-min` and `-max` options.

## Timing Exceptions

Timing exceptions modify the default analysis that is performed by the Quartus II TimeQuest Timing Analyzer. This section describes the following available timing exceptions:

- False path
- Minimum delays
- Maximum delays
- Multicycle path

## Precedence

If a conflict of node names occurs between timing exceptions, the following order of precedence applies:

1. False path
2. Minimum delays and maximum delays
3. Multicycle path

The false path timing exception has the highest precedence. Within each category, assignments to individual nodes have precedence over assignments to clocks. Finally, the remaining precedence for additional conflicts is order-dependent, such that the last assignments overwrite (or partially overwrite) earlier assignments.

## False Path

False paths are paths that can be ignored during timing analysis.

Use the `set_false_path` command to specify false paths in the design.

[Example 6-20](#) shows the `set_false_path` command and options.

---

### Example 6-20. `set_false_path` Command

```
set_false_path
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-hold]
[-setup]
[-through <names>]
<delay>
```

---

[Table 6-16](#) describes the options for the `set_false_path` command.

Option	Description
<code>-fall_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies false path begins at the fall from <code>&lt;clocks&gt;</code> .
<code>-fall_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies false path ends at the fall to <code>&lt;clocks&gt;</code> .
<code>-from &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies false path begins at the <code>&lt;names&gt;</code> .
<code>-hold</code>	Specifies the false path is valid during the hold analysis only.
<code>-rise_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies false path begins at the rise from <code>&lt;clocks&gt;</code> .

**Table 6–16. set\_false\_path Command Options (Part 2 of 2)**

Option	Description
-rise_to <clocks>	The <names> is a collection or list of objects in the design. Specifies false path ends at the rise to <clocks>.
-setup	Specifies the false path is valid during the setup analysis only.
-through <names>	The <names> is a collection or list of objects in the design. Specifies false path passes through <names>.
-to <names>	The <names> is a collection or list of objects in the design. Specifies false path ends at <names>.
<delay>	Specifies the delay value.

When the objects are timing nodes, the false path only applies to the path between the two nodes. When an object is a clock, the false path applies to all paths where the source node (-from) or destination node (-to) is clocked by the clock.

### Minimum Delay

Use the set\_min\_delay command to specify an absolute minimum delay for a given path. The following list shows the set\_min\_delay command and options.

---

#### Example 6–21. set\_min\_delay Command

```
set_min_delay
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-through <names>]
<delay>
```

---

Table 6–17 describes the options for the `set_min_delay` command.

<b>Option</b>	<b>Description</b>
<code>-fall_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the minimum delay begins at the falling edge of <code>&lt;clocks&gt;</code> .
<code>-fall_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the minimum delay ends at the falling of <code>&lt;clocks&gt;</code> .
<code>-from &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the start point of the path.
<code>-rise_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the minimum delay at the rising edge of <code>&lt;clocks&gt;</code> .
<code>rise_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the minimum delay at the rising edge of <code>&lt;clocks&gt;</code> .
<code>-through &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the through point of the path.
<code>-to &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the end point of the path.
<code>&lt;delay&gt;</code>	Specifies the delay value.

If the source or destination node is clocked, the clock paths are taken into account, allowing more or less delay on the data path. If the source or destination node has an input or output delay, that delay is also included in the minimum delay check.

When the objects are timing nodes, the minimum delay applies only to the path between the two nodes. When an object is a clock, the minimum delay applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

You can apply the `set_min_delay` command exception to an output port that does not use a `set_output_delay` constraint. In this case, the setup summary and hold summary report the slack for these paths. Because there is no clock associated with the output port, no clock is reported for these paths and the **Clock** column is empty. In this case, you cannot report timing for these paths.

To report timing using clock filters for output paths with the `set_min_delay` command, you must use the `set_output_delay` command for the output port with a value of 0. You can use an existing clock from the design or a virtual clock as the clock reference in the `set_output_delay` command.

## Maximum Delay

Use the `set_max_delay` command to specify an absolute maximum delay for a given path. [Example 6–22](#) shows the `set_max_delay` command and options.

### Example 6–22. `set_max_delay` Command

```
set_max_delay
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-through <names>]
<delay>
```

[Table 6–18](#) describes the options for the `set_max_delay` command.

Option	Description
<code>-fall_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the maximum delay begins at the falling edge of <code>&lt;clocks&gt;</code> .
<code>-fall_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the maximum delay ends at the falling of <code>&lt;clocks&gt;</code> .
<code>-from &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the start point of the path.
<code>-rise_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the maximum delay at the rising edge of <code>&lt;clocks&gt;</code> .
<code>rise_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the maximum delay at the rising edge of <code>&lt;clocks&gt;</code> .
<code>-through &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the thru point of the path
<code>-to &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the end point of the path
<code>&lt;delay&gt;</code>	Specifies the delay value.

If the source or destination node is clocked, the clock paths are taken into account, allowing more or less delay on the data path. If the source or destination node has an input or output delay, that delay is also included in the maximum delay check.

When the objects are timing nodes, the maximum delay only applies to the path between the two nodes. When an object is a clock, the maximum delay applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

You can apply the `set_max_delay` command exception to an output port that does not use a `set_output_delay` constraint. In this case, the setup summary and hold summary report the slack for these paths. Because there is no clock associated with the output port, no clock is reported for these paths and the **Clock** column is empty. In this case, you cannot report timing for these paths.

To report timing using clock filters for output paths with the `set_max_delay` command, you must use the `set_output_delay` command for the output port with a value of 0. You can use an existing clock from the design or a virtual clock as the clock reference in the `set_output_delay` command.

## Multicycle Path

By default, the Quartus II TimeQuest Timing Analyzer uses a single-cycle analysis. When analyzing a path, the setup launch and latch edge times are determined by finding the closest two active edges in the respective waveforms. For a hold analysis, the timing analyzer analyzes the path against two timing conditions for every possible setup relationship, not just the worst-case setup relationship. Therefore, the hold launch and latch times may be completely unrelated to the setup launch and latch edges.

A multicycle constraint relaxes setup or hold relationships by the specified number of clock cycles based on the source (`-start`) or destination (`-end`) clock. An end multicycle constraint of 2 extends the worst-case setup latch edge by one destination clock period.

Hold multicycle constraints are based on the default hold position (the default value is 0). An end hold multicycle constraint of 1 effectively subtracts one destination clock period from the default hold latch edge.

Use the `set_multicycle_path` command to specify the multicycle constraints in the design. [Example 6-23](#) shows the `set_multicycle_path` command and options.

**Example 6-23. `set_multicycle_path` Command**

```
set_multicycle_path
[-end]
[-fall_from <clocks> | -rise_from <clocks> | -from <names>]
[-fall_to <clocks> | -rise_to <clocks> | -to <names>]
[-hold]
[-setup]
[-start]
[-through <names>]
<path multiplier>
```

[Table 6-19](#) describes the options for the `set_multicycle_path` command.

<b>Table 6-19. <code>set_multicycle_path</code> Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>fall_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the multicycle begins at the falling edge of <code>&lt;clocks&gt;</code> .
<code>fall_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the multicycle ends at the falling of <code>&lt;clocks&gt;</code> .
<code>-from &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the start point of the path.
<code>-hold   -setup</code>	Specifies the type of multicycle to be applied.
<code>-rise_from &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the multicycle at the rising edge of <code>&lt;clocks&gt;</code> .
<code>-rise_to &lt;clocks&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies the multicycle ends at the rising edge of <code>&lt;clocks&gt;</code> .
<code>-start   -end</code>	Specifies whether the start or end clock acts as the source or destination for the multicycle.
<code>-through &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. Specifies multicycle passes through <code>&lt;names&gt;</code> .
<code>-to &lt;names&gt;</code>	The <code>&lt;names&gt;</code> is a collection or list of objects in the design. The <code>&lt;names&gt;</code> acts as the end point of the path.
<code>&lt;path multiplier&gt;</code>	Specifies the multicycle multiplier value.

When the objects are timing nodes, the multicycle constraint only applies to the path between the two nodes. When an object is a clock, the multicycle constraint applies to all paths where the source node (`-from`) or destination node (`-to`) is clocked by the clock.

## Clock-as-Data Analysis

The Quartus II TimeQuest Timing Analyzer has the ability to analyze clock paths as data paths. This analysis plays an important part when determining arrival and required times for source synchronous interfaces, or where clock path is used as a data path (for example, a clock captured by a register). Figure 6–28 shows a typical source synchronous interface.

**Figure 6–28. Simple Source Synchronous Circuit**

To constrain the path from port `clk`, through the PLL, to port `clk_out` you can use a `set_output_delay` to the `clk_out` port, or you can use the `set_max_delay` exception to the `clk_out` port (optionally specifying the PLL clock or PLL output pin as the `-from`). Without the clock as data analysis, this constraint will lose the phase shift associated with the PLL.

With the clock as data analysis the path from port `clk` to port `clk_out` will be analyzed as data path and includes the PLL phase shift. Two paths are reported per analysis: one from the rising edge of the clock source and one from the falling edge of the clock source.

## Application Examples

This section describes specific examples for the `set_multicycle_path` command.

Figure 6–29 shows a register-to-register path where the source clock, `src_clk`, has a period of 10 ns and the destination clock, `dst_clk`, has a period of 5 ns.

**Figure 6–29. Register-to-Register Path**

Figure 6–30 shows the respective timing diagrams for the source and destination clocks and the default setup and hold relationships. The default setup relationship is 5 ns and the default hold relationship is 0 ns.

**Figure 6–30. Default Setup and Hold Timing Diagram**

The default setup and hold relationships can be modified with the `set_multicycle_path` command to accommodate the system requirements.

Table 6–20 shows the commands used to modify either the launch or latch edge times that the TimeQuest Timing Analyzer uses to determine a setup relationship or hold relationship.

<b>Table 6–20. Commands to Modify Edge Times</b>	
<b>Command</b>	<b>Description of Modification</b>
<code>set_multicycle_path -setup -end</code>	Latch edge time of the setup relationship
<code>set_multicycle_path -setup -start</code>	Launch edge time of the setup relationship
<code>set_multicycle_path -hold -end</code>	Latch edge time of the hold relationship
<code>set_multicycle_path -hold -start</code>	Latch edge time of the hold relationship

Figure 6–31 shows the command used to modify the setup latch edge and the resulting timing diagram. The command moves the latch edge time to 10 ns from the default 5 ns.

**Figure 6–31. Modified Setup Diagram**

```
# latch every 2nd edge
set_multicycle_path -from [get_clocks src_clk] -to [get_clocks dst_clk] -setup -end 2
```

## Constraint and Exception Removal

When using the Quartus II TimeQuest Timing Analyzer interactively, it is usually necessary to remove a constraint or exception. In cases where constraints and exceptions either become outdated or have been erroneously entered, the Quartus II TimeQuest Timing Analyzer provides a convenient way to remove them.

Table 6–21 lists commands that allow you to remove constraints and exceptions from a design.

Command	Description
<code>remove_clock [-all] [&lt;clock list&gt;]</code>	Removes any clocks specified by <clock list> that have been previously created. The -all option removes all declared clocks.
<code>remove_clock_groups -all</code>	Removes all clock groups previously created. Specific clock groups cannot be removed.
<code>remove_clock_latency -source &lt;targets&gt;</code>	Removes the clock latency constraint from the clock specified by <targets>.
<code>remove_clock_uncertainty -from &lt;from clock&gt; -to &lt;to clock&gt;</code>	Removes the clock uncertainty constraint from <from clock> to <to clock>.
<code>remove_input_delay &lt;targets&gt;</code>	Removes the input delay constraint from <targets>.
<code>remove_output_delay &lt;targets&gt;</code>	Removes the output delay constraint from <targets>.
<code>reset_design</code>	Removes all constraints and exceptions in the design.

## Timing Reports

The Quartus II TimeQuest Timing Analyzer provides real-time static timing analysis result reports. Reports are generated only when requested. Each report can be customized to display specific timing information, excluding those fields not required.

This section describes the various report generation commands supported by the Quartus II TimeQuest Timing Analyzer.

### report\_timing

Use the `report_timing` command to generate a setup, hold, recovery, or removal report. [Example 6–24](#) shows the `report_timing` command and options.

---

#### **Example 6–24. report\_timing Command**

```
report_timing
[-append]
[-detail <summary | path_only | path_and_clock | full_path>]
[-from <names>]
[-to <names>]
[-file <name>]
[-fall_from_clock <names> | -rise_from_clock <names> -from_clock <names>]
[-hold]
[-less_than_slack <slack limit>]
[-npaths <number>]
[-nworst <number>]
[-recovery]
[-removal]
[-setup]
[-stdout]
[-through <names>]
[-through <names>]
[-to_clock <names>]
[-panel_name <name>]
[-fall_to_clock <names> | -rise_to_clock <names>]
```

---

[Table 6–22](#) describes the options for the `report_timing` command.

<b>Table 6–22. report_timing Command Options (Part 1 of 2)</b>	
<b>Option</b>	<b>Description</b>
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .

**Table 6–22. report\_timing Command Options (Part 2 of 2)**

Option	Description
-detail <summary   path_only   path_and_clock   full_path>	Specifies whether or not the clock path detail is reported. <b>Path Only:</b> Clock network delay is lumped together <b>Summary:</b> Lists each individual path <b>Path and Clock:</b> Clock network delay is shown in detail <b>Full Path:</b> More clock network details, in particular for generated clocks
-fall_from_clock <names>	Specifies the falling edge of the <names> from the source register to be analyzed. The options from_clock, fall_from_clock, and rise_from_clock are mutually exclusive.
-fall_to_clock <names>	Specifies the falling edge of the <names> to the destination register to be analyzed. The options to_clock, fall_to_clock, and rise_to_clock are mutually exclusive.
-file <names>	Indicates that the current report is written to the file <name>.
-hold	Specifies a clock hold analysis.
-less_than_slack <slack limit>	Limits the paths to be reported to those the <slack limit> value.
-npaths <number>	Specifies the number of paths to report.
-nworst <number>	Restricts the number of paths per endpoint.
-panel_name <names>	Specifies the name of the panel in the <b>Reports</b> pane.
-recovery	Specifies a recovery analysis.
-removal	Specifies a removal analysis.
-rise_from_clock <names>	Specifies the rising edge of the <names> from the source register to be analyzed. The options from_clock, fall_from_clock, and rise_from_clock are mutually exclusive.
-rise_to_clock <names>	Specifies the rising edge of the <names> to the destination register to be analyzed. The options to_clock, fall_to_clock, and rise_to_clock are mutually exclusive.
-setup	Specifies a clock setup analysis.
-stdout	Indicates the report be sent to stdout.
-through <names>	Specifies the through node for the analysis.
-to <names>	Specifies the to node for the analysis.
-to_clock <names>	Specifies the destination clock for the analysis.
-panel_name <names>	Sends the results to the panel and specifies the name of the new panel.

Example 6–25 shows a sample report that results from typing the following command:

```
report_timing -from_clock clk_async -to_clock clk_async -setup -npaths 1 ←
```

**Example 6–25. Sample report\_timing Report**

```

---

The report\_timing command generates a report of the specified analysis type—either setup, hold, recovery, or removal. Each report contains various columns for the data arrival times and data required time, specifically:

- Total
- Incr
- RF
- Type
- Fanout
- Location
- Element

Each of the four column descriptions are described in the [Table 6–23](#).

All columns appear only when a report panel is created. If the `report_timing` output is directed to a file or the console, only the Total, Incr, RF, Type and Node columns appear.

Column Name	Description
Total	Shows the accumulated time delay
Incr	Shows the increment in delay
RF	Shows the input and output transition of the element; this can be one of the following: R, F, RR, RF, FR, FF
Type	Shows the node type; refer to <a href="#">Table 6–24</a> of a description of the various node types
Fanout	Shows the number of fan-outs of the element
Location	Shows the location of the element in the FPGA
Element	Shows the name element

[Table 6–24](#) provides a description of the possible node Type in the `report_timing` reports.

Type Name	Description
CELL	Indicates the element is either a register or a combinational element in the FPGA; the CELL can be a register in the ALM, memory blocks, or DSP blocks
COMP	Indicates the PLL clock network compensation delay
IC	Indicates the element is an interconnect delay
$\mu t_{CO}$	Indicates the element's micro clock-to-out time
$\mu t_{SU}$	Indicates the element's micro setup time
$\mu t_{H}$	Indicates the element's micro hold time
$i_{EXT}$	Indicates the element's external input delay time
$o_{EXT}$	Indicates the element's external output delay time

## report\_clock\_transfers

Use the `report_clock_transfers` command to generate a report that details all clock-to-clock transfers in the design. A clock-to-clock transfer is reported if a path exists between two registers that are clocked by two different clocks. Information such as the number of destinations and sources is also reported.

Use the `report_clock_transfers` command to generate a setup, hold, recovery, or removal report.

[Example 6-26](#) shows the `report_clock_transfers` command and options.

---

### Example 6-26. report\_clock\_transfers Command

```
report_clock_transfers
[-append]
[-file <name>]
[-hold]
[-setup]
[-stdout]
[-recovery]
[-removal]
[-panel_name <name>]
```

---

[Table 6-25](#) describes the options for the `report_clock_transfers` command.

<b>Table 6-25. report_clock_transfers Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-hold</code>	Creates a clock transfer summary for hold analysis.
<code>-setup</code>	Creates a clock transfer summary for setup analysis.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-recovery</code>	Creates a clock transfer summary for recovery analysis.
<code>-removal</code>	Creates a clock transfer summary for removal analysis.
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

## report\_clocks

Use the `report_clocks` command to generate a report that details all clocks in the design. The report contains information such as type, period, waveform (rise and fall), and targets for all clocks in the design.

[Example 6–27](#) shows the `report_clocks` command and options.

### Example 6–27. report\_clocks Command

```
report_clocks
[-append]
[-desc]
[-file <name>]
[-stdout]
[-panel_name <name>]
```

[Table 6–26](#) describes the options for the `report_clocks` command.

Option	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-desc</code>	Specifies the clock names to sort in descending order. The default is ascending order.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

## report\_min\_pulse\_width

A minimum pulse width checks that a clock high or low pulse is sustained enough to recognize an actual change in the clock signal. A failed minimum pulse width check indicates that the register may not recognize the clock transition. Use the `report_min_pulse_width` command to generate a report that details the minimum pulse width for all clocks in the design. The report contains information for high and low pulses for all clocks in the design.

The `report_min_pulse_width` command also reports minimum period checks for RAM and DSP, as well as I/O edge rate limits for input and output clock ports. For output ports, the port must either have a clock (or generated clock) assigned to it or used as the `-reference_pin` for an input/output delays.

The `report_min_pulse_width` command checks the I/O edge rate limits, but does not always perform the check for output clock ports. For the `report_min_pulse_width` command to check the I/O edge rate limits for output clock ports the output clock port must:

- Have a clock or generated clock constraint assigned to it

*or*

- Be used as a `-reference_pin` for an Input or Output delay constraint

Each register in the design is reported twice per clock that clocks the register: once for the high pulse and once for the low pulse. [Example 6–28](#) shows the `report_min_pulse_width` command and options.

**Example 6–28. report\_min\_pulse\_width Command**

```
report_min_pulse_width
[-append]
[-file <name>]
[-nworst <number>]
[-stdout]
[<targets>]
[-panel_name <name>]
```

[Table 6–27](#) describes the options for the `report_min_pulse_width` command.

<i>Table 6–27. report_min_pulse_width Command Options</i>	
Option	Description
<code>-append</code>	If output is sent to a file, this option appends the result to that file. Otherwise, the file is overwritten.
<code>-file &lt;name&gt;</code>	Sends the results to a file.
<code>-nworst &lt;number&gt;</code>	Specifies the number of pulse width checks to report. The default is 1.
<code>-stdout</code>	Redirects the output to <code>stdout</code> via messages; only required if another output format, such as a file, has been selected and is also to receive messages.
<code>-targets</code>	Specifies registers.
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

## report\_net\_timing

Use the `report_net_timing` command to generate a report that details the delay and fan-out information about a net in the design. A net corresponds to a cell's output pin.

Example 6–29 shows the `report_net_timing` command and options.

---

### Example 6–29. report\_net\_timing Command

```
report_net_timing
[-append]
[-file <name>]
[-nworst_delay <number>]
[-nworst_fanout <number>]
[-stdout]
[-panel_name <name>]
```

---

Table 6–28 describes the options for the `report_net_timing` command.

<b>Table 6–28. report_net_timing Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-nworst_delay &lt;number&gt;</code>	Specifies that <code>&lt;number&gt;</code> worst net delays be reported.
<code>-nworst_fanout &lt;number&gt;</code>	Specifies that <code>&lt;number&gt;</code> worst net fan-outs be reported.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

## report\_sdc

Use the use the `report_sdc` command to generate a report of all the Synopsys Design Constraints in the project.

[Example 6–30](#) shows the `report_sdc` command and options.

---

### Example 6–30. report\_sdc Command

```
report_sdc
[-ignored]
[-append]
[-file]
[-stdout]
[-panel_name <name>]
```

---

[Table 6–29](#) describes the options for the `report_sdc` command.

<i>Table 6–29. report_sdc Command Options</i>	
Option	Description
-ignored	Reports assignments that were ignored.
-append	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
-file	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
-stdout	Indicates that the report is sent to <code>stdout</code> .
-panel_name <code>&lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

## report\_ucp

Use the `report_ucp` command to generate a report of all unconstrained paths in the design.

[Example 6–31](#) shows the `report_ucp` command and options.

---

### Example 6–31. report\_ucp Command

```
report_ucp
[-append]
[-file <name>]
[-hold]
[-setup]
[-stdout]
[-summary]
[-panel_name <name>]
```

---

Table 6–30 describes the options for the `report_ucp` command.

Option	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-hold</code>	Report all unconstrained hold paths.
<code>-setup</code>	Report all unconstrained setup paths.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-summary</code>	Generates only the summary panel.
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

Table 6–31 summarizes all reporting commands available in the Quartus II TimeQuest Timing Analyzer.

Task Pane Report	Tcl Command	Description
Report Setup Summary	<code>create_timing_summary -setup</code>	Generates a clock setup summary for all defined clocks.
Report Hold Summary	<code>create_timing_summary -hold</code>	Generates a clock hold summary for all defined clocks.
Report Recovery Summary	<code>create_timing_summary -recovery</code>	Generates a clock recovery summary for all defined clocks.
Report Removal Summary	<code>create_timing_summary -removal</code>	Generates a clock removal summary for all defined clocks.
Report Clocks	<code>report_clocks</code>	Generates a clock summary for all defined clocks.
Report Clock Transfers	<code>report_clock_transfers</code>	Generates a clock transfer summary for all clock-to-clock transfers in the design.
Report SDC	<code>report_sdc</code>	Generates a summary of all SDC file commands read.
Report Unconstrained Paths	<code>report_ucp</code>	Generates a summary of all unconstrained paths in the design.
Report Timing	<code>report_timing</code>	Generates a detailed summary for specific paths in the design.
Report Net Timing	<code>report_net_timing</code>	Generates a detailed summary for specific nets in the design.

**Table 6–31. Reports from the Tasks Pane and Tcl Commands (Part 2 of 2)**

Task Pane Report	Tcl Command	Description
Report Minimum Pulse Width	report_min_pulse_width	Generates a detailed summary for specific registers in the design.
Create Slack Histogram	create_slack_histogram	Generates a detailed histogram for a specific clock in the design.

### report\_path

Use the report\_path command to report the longest delay paths and the corresponding delay value.

Example 6–32 shows the report\_path command and options.

#### Example 6–32. report\_path Command

```
report_path
[-append]
[-file <name>]
[-from <names>]
[-npaths <number>]
[-stdout]
[-through]
[-to <names>]
[-panel_name <name>]
```

Table 6–32 describes the options for the report\_path command.

**Table 6–32. report\_path Command Options**

Option	Description
-append	Specifies that the current report be appended to the file specified by the -file option.
-file <name>	Indicates that the current report is written to the file <name>.
-from <names>	Specifies the source node for the analysis.
-npaths <number>	Specifies the number of paths to report.
-stdout	Indicates the report be sent to stdout.
-through <name>	Specifies the through node for the analysis.
-to <names>	Specifies the destination node for the analysis.
-panel_name <name>	Sends the results to the panel and specifies the name of the new panel.

## report\_datasheet

Use the `report_datasheet` command to generate a datasheet report which summarizes the timing characteristics of the entire design. It reports setup (`tsu`), hold (`th`), clock-to-output (`tco`), minimum clock-to-output (`mintco`), propagation delay (`tpd`), and minimum propagation delay (`mintpd`) times. [Example 6–33](#) shows the `report_datasheet` command and options.

### Example 6–33. report\_datasheet Command

```
report_datasheet
[-append]
[-file <name>]
[-stdout]
[panel_name <name>]
```

[Table 6–33](#) describes the options for the `report_datasheet` command.

<b>Table 6–33. report_datasheet Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

The delays are reported with respect to a base clock or port for which they are relevant. If there is a case where there are multiple paths for a clock, the maximum delay of the longest path is taken for the `tsu`, `th`, `tco`, and `tpd`, and the minimum delay of the shortest path is taken for `mintco` and `mintpd`.

## report\_rskm

Use the `report_rskm` command to generate a report that details the receiver skew margin for LVDS receivers.

[Example 6–34](#) shows the `report_rskm` command and options.

---

### **Example 6–34. report\_rskm Command**

```
report_rskm
[-append]
[-file <name>]
[-panel_name <name>]
[-stdout]
```

---

[Table 6–34](#) describes the options for the `report_rskm` command.

<i>Table 6–34. report_rskm Command Options</i>	
Type Name	Description
-append	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
-file <name>	Indicates that the current report is written to the file <name>.
-panel_name <name>	Sends the results to the panel and specifies the name of the new panel.
-stdout	Indicates the report be sent to <code>stdout</code> .

## report\_tccs

Use the `report_tccs` command to generate a report that details the channel-to-channel skew margin for LVDS transmitters.

[Example 6–35](#) shows the `report_tccs` command and options.

---

### **Example 6–35. report\_tccs Command**

```
report_tccs
[-append]
[-file <name>]
[-panel_name <name>]
[-quiet]
[-stdout]
```

---

Table 6–35 describes the options for the `report_tccs` command.

Type Name	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.
<code>-quiet</code>	Specifies that nothing will be printed if there are no LVDS receivers in the design.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .

## report\_path

Use the `report_path` command to generate a report that details the longest delay paths between any two arbitrary keeper nodes.

Example 6–36 shows the `report_path` command and options.

### Example 6–36. report\_path Command

```
report_path
[-append]
[-file <name>]
[-from <names>]
[-min_path]
[-npaths <number>]
[-nworst <number>]
[-panel_name <name>]
[-stdout]
[-summary]
[-through <names>]
[-to <names>]
```

Table 6–36 describes the options for the `report_path` command.

Type Name	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .

**Table 6–36. report\_path Command Options (Part 2 of 2)**

Type Name	Description
-from <names>	The <names> is a collection or list of objects in the design. The <names> acts as the start point of the path.
-min_path	Displays the minimum delay paths.
-npaths <number>	Specifies the number of paths to report.
-nworst <number>	Specifies the maximum number of paths to report for each endpoint.
-panel_name <name>	Sends the results to the panel and specifies the name of the new panel.
-stdout	Indicates the report be sent to stdout.
-summary	Creates a single table with a summary of each path found.
-through <names>	The <names> is a collection or list of objects in the design. Specifies false path passes through <names>.
-to <names>	The <names> is a collection or list of objects in the design. The <names> acts as the end point of the path.

The delay path reported cannot pass through a keeper node, for example, a register or port. Instead, the delay path must be from the output pin of a keeper node to the input pin of a keeper node.

Figure 6–32 shows a simple design with a register-to-register path.

**Figure 6–32. Simple Register-to-Register Path**

Example 6–37 shows the report generated from the following command:

```
report_path -from [get_pins {reg1|regout}] -to [get_pins \
{reg2|datain}] -npaths 1 -panel_name "Report Path" -stdout
```

**Example 6–37. report\_path from Keeper Output Pin to Keeper Input Pin**

```

Info: =====
Info: From Node : reg1|regout
Info: To Node : reg2|datain
Info:
Info: Path:
Info:
Info: Total (ns)  Incr (ns)  Type Element
Info: =====  =====  ==  =====

Info: 0.360 0.154 RR CELL and2|combout
Info: 0.360 0.000 RR IC reg2|datain
Info:
Info: Total Path Delay : 0.360
Info: =====

```

**Example 6–38** shows the report generated from the following command:

```

> report_path -from [get_ports data_in_a] -to [get_pins \
  {reg2|regout}] -npaths 1

```

**Example 6–38. report\_path from Keeper-to-Keeper Output Pin**

```

Info: Report Path: No paths were found
0 0.000

```

No paths were reported in **Example 6–38** because the destination passes through an input pin of a keeper node.

**check\_timing**

Use the `check_timing` command to generate a report on any potential problem with the design or applied constraints. Not all `check_timing` results are serious issues, and the results should be examined to see if the results are desired. **Example 6–39** shows the `check_timing` command and options.

**Example 6–39. check\_timing Command**

```

check_timing
[-append]
[-file <name>]
[-include <check_list>]
[-stdout]
[-panel_name <name>]

```

Table 6–37 describes the options for the `check_timing` command.

Option	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-include</code>	Indicates that a check is to be performed with the <code>&lt;check_list&gt;</code> . Refer to Table 6–38 for a list of checks.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

Table 6–38 describes the possible checks.

Option	Description
<code>no_clock</code>	Checks that registers have at least one clock at their clock pin, and that ports determined to be clocks have a clock assigned to them.
<code>multiple_clock</code>	Checks that registers have at most one clock at their clock pin. When multiple clocks reach a register's clock pin, both clocks will be used for analysis.
<code>generated_clock</code>	Checks that generated clocks are valid. Generated clocks must have a source that is clocked by a valid clock. They must also not depend on each other in a loop ( <code>clk1</code> cannot have <code>clk2</code> as a source if <code>clk2</code> already uses <code>clk1</code> as a source).
<code>no_input_delay</code>	Checks that every input port that is not determined to be a clock has an input delay set on it.
<code>no_output_delay</code>	Checks that every output port has an output delay set on it.
<code>partial_input_delay</code>	Checks that input delays are complete. Makes sure that input delays have a rise-min, fall-min, rise-max, and fall-max portion set.
<code>partial_output_delay</code>	Checks that output delays are complete. Makes sure that output delays have a rise-min, fall-min, rise-max, and fall-max portion set.
<code>reference_pin</code>	Checks if reference pins specified in <code>set_input_delay</code> and <code>set_output_delay</code> using the <code>reference_pin</code> option are valid. A <code>reference_pin</code> is valid if the clock option specified in the same <code>set_input_delay/set_output_delay</code> command matches the clock that is in the direct fan-in of the <code>reference_pin</code> . Being in the direct fan-in of the <code>reference_pin</code> means that there must be no keepers between the clock and the <code>reference_pin</code> .

**Table 6–38. Possible Checks (Part 2 of 2)**

Option	Description
latency_override	Checks if the clock latency constraint that is set on a port or pin overrides the more generic clock latency set on a clock. Clock latency can be set on a clock, where the latency applies to all keepers clocked by the clock, whereas clock latency can also be set on a port or pin, where the latency applies to registers in the fan-out of the port or pin.
loops	Checks that there are no strongly connected components in the design. These loops prevent a design from being properly analyzed. Indicates that loops exist but were marked so that they would not be traversed.
latches	Checks if there are latches in the design. The Quartus II TimeQuest Timing Analyzer warns the user that the latches exist and cannot be properly analyzed.

Example 6–40 shows how the `check_timing` command can be used.

---

**Example 6–40. The `check_timing` Command**

```
# Constrain design
create_clock -name clk -period 4.000 -waveform { 0.000 2.000 } \
  [get_ports clk]
set_input_delay -clock clk2 1.5 [get_ports in*]
set_output_delay -clock clk 1.6 [get_ports out*]
set_false_path -from [get_keepers in] -through [get_nets r1] -to \
  [get_keepers out]

# Check if there were any problems
check_timing -include {loops latches no_input_delay partial_input_delay}
```

---

### report\_clock\_fmax\_summary

Use the `report_clock_fmax_summary` to report potential  $f_{MAX}$  for every clock in the design, regardless of the user-specified clock periods.  $f_{MAX}$  is only computed for paths where the source and destination registers or ports are driven by the same clock. Paths of different clocks, including generated clocks, are ignored. For paths between a clock and its inversion,  $f_{MAX}$  is computed as if the rising and falling edges are scaled along with  $f_{MAX}$ , such that the duty cycle (in terms of a percentage) is maintained.

Example 6-41 shows the `report_clock_fmax_summary` command and options.

---

**Example 6-41. `report_clock_fmax_summary` Command**

```
report_clock_fmax_summary
[-append]
[-file <name>]
[-panel_name <name>]
[-stdout]
```

---

Table 6-39 describes the options for the `report_clock_fmax_summary` command.

<b>Table 6-39. <code>report_clock_fmax_summary</code> Command Options</b>	
<b>Option</b>	<b>Description</b>
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.

**`create_timing_summary`**

Reports the worst-case Clock Setup and Clock Hold slacks and endpoint TNS (total negative slack) per clock domain. Total negative slack is the sum of all slacks less than zero for each destination register or port in the clock domain.

Example 6-42 shows the `create_timing_summary` command and options.

---

**Example 6-42. `create_timing_summary` Command**

```
create_timing_summary
[-append]
[-file <name>]
[-hold]
[-panel_name <name>]
[-recovery]
[-removal]
[-setup]
[-stdout]
```

---

Table 6–40 describes the options for the `create_timing_summary` command.

Option	Description
<code>-append</code>	Specifies that the current report be appended to the file specified by the <code>-file</code> option.
<code>-file &lt;name&gt;</code>	Indicates that the current report is written to the file <code>&lt;name&gt;</code> .
<code>-hold</code>	Generates a clock hold check summary report.
<code>-panel_name &lt;name&gt;</code>	Sends the results to the panel and specifies the name of the new panel.
<code>-recovery</code>	Generates a recovery check summary report.
<code>-removal</code>	Generates a removal check summary report.
<code>-setup</code>	Generates a clock setup check summary report.
<code>-stdout</code>	Indicates the report be sent to <code>stdout</code> .

## Timing Analysis Features

### Multi-Corner Analysis

Multi-corner analysis allows a design to be verified under a variety of operating conditions (voltage, process, and temperature) while performing a static timing analysis on the design.

Use the `set_operating_conditions` command to change the operating conditions of the device used for static timing analysis.

Example 6–43 shows the `set_operating_conditions` command and options.

---

#### **Example 6–43. `set_operating_conditions` Command**

```
set_operating_conditions
[-model <fast|slow>]
[-speed <speed grade>]
[-temperature <value in °C>]
[-voltage <value in mV>]
[<operating condition Tcl object>]
```

---

Table 6–41 describes the options for the `report_net_timing` command.

Option	Description
<code>-model &lt;fast slow&gt;</code>	Specifies the timing model.
<code>-speed &lt;speed grade&gt;</code>	Specifies the device speed grade.
<code>-temperature &lt;value in °C&gt;</code>	Specifies the operating temperature.
<code>-voltage &lt;value in mV&gt;</code>	Specifies the operating voltage.
<code>&lt;operating condition Tcl object&gt;</code>	Specifies the operating condition Tcl object that specifies the operating conditions.

If an operating condition Tcl object *is* used, the model, speed, temperature, and voltage options are not required. If an operating condition Tcl object is *not* used, the model must be specified, and the `-speed`, `-temperature`, and `-voltage` options are optional, using the appropriate defaults for the device where applicable.

Table 6–42 shows the available operating conditions that can be set for each device family.

Device Family	Available Conditions			Operating Condition Tcl Objects
	Model	Voltage (mV)	Temp (°C)	
Stratix III	Slow	1100	85	slow_1100mv_85c slow_1100mv_0c fast_1100mv_0c
	Slow	1100	0	
	Fast	1100	0	
Cyclone III	Slow	1200	85	slow_1200mv_85c slow_1200mv_0c fast_1200mv_0c
	Slow	1200	0	
	Fast	1200	0	
Stratix II	Slow	N/A	N/A	slow fast
	Fast			
Cyclone II	Slow	N/A	N/A	slow fast
	Fast			

Use the command `get_available_operating_conditions` to obtain a list of available operating conditions for the target device.

Example 6–44 shows how to set the operating conditions for a Stratix III design to the slow model, 1100 mV, and 85°C.

---

**Example 6–44. Setting Operating Conditions with Individual Values**

```
set_operating_conditions -model slow -temperature 85 -voltage 1100
```

---

Alternatively, the operating conditions in Example 6–44 can be set with the Tcl object as shown in Example 6–45.

---

**Example 6–45. Setting Operating Conditions with a Tcl Object**

```
set_operating_conditions slow_1100mv_85c
```

---

## Advanced I/O Timing and Board Trace Model Assignments

The Quartus II TimeQuest Timing Analyzer is able to use Advanced I/O Timing and Board Trace Model assignments to model I/O buffer delays in your design. The Advanced I/O Analysis feature can be turned ON or OFF in the **Settings** dialog box under the **TimeQuest Timing Analyzer** option.

If you turn ON or OFF the **Advanced I/O Timing** or change Board Trace Model assignments and do not recompile before you analyze timing, you must use the `-force_dat` option when you create the timing netlist. Type the following command at the Tcl console of the Quartus II TimeQuest Timing Analyzer:

```
create_timing_netlist -force_dat ↵
```

If you turn ON or OFF the Advanced I/O Timing or change Board Trace Model assignments and do recompile before you analyze timing, you do not need to use the `-force_dat` option when you create the timing netlist. You can create the timing netlist with the `create_timing_netlist` command, or with the **Create Timing Netlist** task in the **Tasks** pane.

For more information about the Advanced I/O Timing feature, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

## Wildcard Assignments and Collections

To simplify the task of applying constraints to many nodes in a design, the Quartus II TimeQuest Timing Analyzer accepts the “\*” and “?” wildcard characters. Use these wildcard characters to reduce the number of individual constraints you must specify in your design.

The “\*” wildcard character matches any string. For example, given an assignment made to a node specified as `reg*`, the Quartus II TimeQuest Timing Analyzer searches for and applies the assignment to all design nodes that match the prefix `reg` with none, one, or several characters following, such as `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

The “?” wildcard character matches any single character. For example, given an assignment made to a node specified as `reg?`, the Quartus II TimeQuest Timing Analyzer searches and applies the assignment to all design nodes that match the prefix “`reg`” and any single character following, for example, `reg1`, `rega`, and `reg4`.

Both the collection commands `get_cells` and `get_pins` have three options that allow you to refine searches that include the wildcard character. To refine your search results, select the default behavior, the `-hierarchical` option, or the `-compatibility` option.

 The pipe character is used to separate one hierarchy level from the next in the Quartus II TimeQuest Timing Analyzer. For example, `<absolute full cell name>|<pin suffix>` represents a hierarchical pin name with the “|” separating the hierarchy from the pin name.

When you use the collection commands `get_cells` and `get_pins` without an option, the default search behavior is performed on a per-hierarchical level of the pin name, that is, the search is performed level by level. A full hierarchical name may contain multiple hierarchical levels where a “|” is used to separate the hierarchical levels, and each wildcard character represents only one hierarchical level. For example, “\*” represents the first hierarchical level and “\*|\*” represents the first and second hierarchical levels.

When you use the collection commands `get_cells` and `get_pins` with the `-hierarchical` option, a recursive match is performed on the relative hierarchical path name of the form `<short cell name>|<pin name>`. The search is performed on the node name, for example, the last hierarchy of the name, and not the hierarchy path. Unlike the default behavior, this option does not limit the search to each hierarchy level represented by the pipe character.

 The pipe character cannot be used in the search with the `get_cells -hierarchical` option. The pipe character can be used with the `get_pins` collection search.

When you use the collection commands `get_cells` and `get_pins` with the `-compatibility` option, the search performed is similar to that of the Quartus II Classic Timing Analyzer. This option searches the entire hierarchical path, and pipe characters are not treated as special characters.

Assuming the following cells exist in a design:

```
foo
foo|bar
```

and the following pin names:

```
foo|dataa
foo|datab
foo|bar|datac
foo|bar|datad
```

Table 6–43 shows the results of using these search strings.

Search String	Search Result
<code>get_pins * dataa</code>	foo dataa
<code>get_pins * datac</code>	<empty>
<code>get_pins * * datac</code>	foo bar datac
<code>get_pins foo* *</code>	foo dataa, foo datab
<code>get_pins -hierarchical * * datac</code>	<empty> (1)
<code>get_pins -hierarchical foo *</code>	foo dataa, foo datab
<code>get_pins -hierarchical * datac</code>	foo bar datac
<code>get_pins -hierarchical foo * datac</code>	<empty> (1)
<code>get_pins -compatibility * datac</code>	foo bar datac
<code>get_pins -compatibility * * datac</code>	foo bar datac

**Note to Table 6–43:**

(1) Due to the additional `*|*` in the search string, the search result is <empty>.

## Resetting a Design

Use the `reset_design` command to remove all timing constraints and exceptions from the design under analysis. The command removes all clocks, generated clocks, derived clocks, input delays, output delays, clock latency, clock uncertainty, clock groups, false paths, multicycle paths, min delays, and max delays.

This command provides a convenient way to return to the initial state of analysis without the need to delete and re-create a new timing netlist.

## The TimeQuest Timing Analyzer GUI

The Quartus II TimeQuest Timing Analyzer provides an intuitive and easy-to-use GUI that allows you to efficiently constrain and analyze your designs. The GUI consists of the following panes:

- “The Quartus II Software Interface and Options” described on page 6–83
- “View Pane” described on page 6–85
- “Tasks Pane” described on page 6–87
- “Console Pane” described on page 6–90
- “Report Pane” described on page 6–90
- “Constraints” described on page 6–90
- “Name Finder” described on page 6–92
- “Target Pane” described on page 6–94
- “SDC Editor” described on page 6–94

Each pane provides features that enhance productivity (Figure 6–33).

Figure 6–33. The TimeQuest GUI

## The Quartus II Software Interface and Options

The Quartus II software allows you to configure various options for the Quartus II TimeQuest Timing Analyzer report generation that are generated in the Compilation Report for the design.

The TimeQuest Timing Analyzer settings, in the **Settings** dialog box, allow you to configure the options shown in Table 6–44.

Table 6–44. The Quartus II TimeQuest Timing Analyzer Settings (Part 1 of 2)

Options	Description
SDC files to include in the project	Adds and removes SDC files associated with the project
Enable Advanced I/O Timing	Generates advanced I/O timing results from board trace models specified for each pin

**Table 6–44. The Quartus II TimeQuest Timing Analyzer Settings (Part 2 of 2)**

Options	Description
Enable multicorner timing analysis during compilation	Generates multiple reports for all available operating conditions of the target device
Report worst-case paths during compilation	Generates worst-case path reports per clock domain
Tcl Script File for customizing report during compilation	Specifies any custom scripts to be sourced for any custom report generation

The options shown in Table 6–44 only control the reports generated in the Compilation Report, and do not control the reports generated in the Quartus II TimeQuest Timing Analyzer.

Figure 6–34 shows the TimeQuest Timing Analyzer setting.

**Figure 6–34. TimeQuest Timing Analyzer Settings**

## View Pane

The **View** pane is the main viewing area for the timing analysis results. Use the **View** pane to view summary reports, custom reports, or histograms. [Figure 6–35](#) shows the **View** pane after you select the Summary (Setup) report from the **Report** pane.

**Figure 6–35. Summary (Setup) Report**

Summary (Setup)			
	Clock	Slack	End Point TNS
1	inclk:0	0.303	0.000
2	altpll0:instaltpll:altpll_component_clk:0	0.384	0.000

### View Pane: Splitting

For the proper analysis of timing results, comparison of multiple reports is extremely important. To facilitate multiple report viewing, the **View** pane supports window splitting. Window splitting divides the **View** pane into multiple windows, allowing you to view different reports side-by-side.

You can split the **View** pane into multiple windows using the split icon located in the upper right hand corner of the **View** pane. Drag the icon in different directions to generate additional window views in the **View** pane. For example, if you drag the split icon to the left, the **View** pane creates a new window to the right of the current window ([Figure 6–36](#)).

**Figure 6–36. Splitting the View Pane to the Left (Before and After Split Left)**

Summary (Setup)			
	Clock	Slack	End Point TNS
1	inclk:0	0.303	0.000
2	altpll0:instaltpll:altpll_component_clk:0	0.384	0.000

Summary (Setup)				Summary (Setup)			
	Clock	Slack	End Point TNS		Clock	Slack	End Point TNS
1	inclk:0	0.303	0.000	1	inclk:0	0.303	0.000
2	altpll0:instaltpll:altpll_component_clk:0	0.384	0.000	2	altpll0:instaltpll:altpll_component_clk:0	0.384	0.000

If you drag the split icon diagonally, the **View** pane creates three new windows in the **View** pane (Figure 6–37).

**Figure 6–37. Splitting the View Pane Diagonally (Before and After Diagonal Split)**

Drag the split icon downward to create a new window directly below the current window.

*View Pane: Removing Split Windows*

You can remove windows that you create in the **View** pane using the split icon by dragging the border of the window over the window you wish to remove (Figure 6–38).

**Figure 6–38. Removing a Split Window (Before and After Split is Removed)**

## Tasks Pane

Use the **Tasks** pane to access common commands such as netlist setup report generation.

Common commands are located in the **Tasks** pane: **Open Project** and **Write SDC File**, and **Reset Design**. The other commands, including timing netlist setup and the generation of reports, are contained in the following folders:

- **Netlist Setup**
- **Reports**

 Each command in the **Tasks** pane has an equivalent Tcl command that is displayed in the **Console** pane when the command runs.

### *Opening a Project and Writing a Synopsys Design Constraints File*

To open a project in the Quartus II TimeQuest Timing Analyzer, double-click the **Open Project** task. If you launch the Quartus II TimeQuest Timing Analyzer from the Quartus II software GUI, the project opens automatically.

You can add or remove constraints from the timing netlist after the Quartus II TimeQuest Timing Analyzer reads the initial SDC file. After the file is read, the initial SDC file becomes outdated compared to the constraints in the Quartus II TimeQuest Timing Analyzer. Use the **Write SDC File** command to generate an SDC file that is up-to-date and reflects the current state of constraints in the Quartus II TimeQuest Timing Analyzer.

### Netlist Setup Folder

The **Netlist Setup** folder contains tasks that are used to set up the timing netlist for timing analysis. The three tasks located in this folder are **Create Timing Netlist**, **Read SDC File**, and **Update Timing Netlist**.

Use the **Create Timing Netlist** task to create a netlist that the Quartus II TimeQuest Timing Analyzer uses to perform static timing analysis. This netlist is used only for timing analysis by the Quartus II TimeQuest Timing Analyzer.

 You must always create a timing netlist before you perform static timing analysis with the Quartus II TimeQuest Timing Analyzer.

Use the **Read SDC File** command to apply constraints to the timing netlist. By default, the **Read SDC File** command reads the `<current revision>.sdc` file.

 Use the `read_sdc` command to read an SDC file that is not associated with the current revision of the design.

Use the **Update Timing Netlist** command to update the timing netlist after you enter constraints. You should use this command if any constraints are added or removed from the design.

### Reports Folder

The **Reports** folder contains commands to generate timing summary reports of the static timing analysis results. The nine commands located in this folder are summarized in [Table 6-45](#).

**Table 6-45. Reports Folder Commands (Part 1 of 2)**

Report Task	Description
Report $f_{MAX}$ Summary	Generates a $f_{MAX}$ summary report for all clocks in the design.
Report Setup Summary	Generates a clock setup summary report for all clocks in the design.

**Table 6–45. Reports Folder Commands (Part 2 of 2)**

Report Task	Description
Report Hold Summary	Generates a clock hold summary report for all clocks in the design.
Report Recovery Summary	Generates a recovery summary report for all clocks in the design.
Report Removal Summary	Generates a removal summary report for all clocks in the design.
Report Clocks	Generates a summary report of all created clocks in the design.
Report Clock Transfers	Generates a summary report of all clock transfers detected in the design.
Report Minimum Pulse Width	Generates a summary report of all minimum pulse widths in the design.
Report SDC	Generates a summary report of the constraints read from the SDC file.
Report Unconstrained Paths	Generates a summary report of all unconstrained paths in the design.
Report Ignored Constraints	Generates a summary report of all ignored SDC constraints for the design.
Report Datasheet	Generates a datasheet report for the design.

### Macros Folder

The **Macros** folder contains commands that perform custom tasks available in the Quartus II TimeQuest Timing Analyzer utility package. These commands are: **Report All Summaries**, **Report Top Failing Paths**, and **Create All Clock Histograms**.

Table 6–46 describes the commands available in the Macros folder.

**Table 6–46. Macros Folder Commands**

Macro Task	Description
Report All Summaries	This command runs the <b>Report Setup Summary</b> , <b>Report Hold Summary</b> , <b>Report Recovery Summary</b> , <b>Report Removal Summary</b> , and <b>Minimum Pulse Width</b> commands to generate all summary reports.
Report Top Failing Paths	This command generates a report containing a list of top failing paths.
Create All Clock Histograms	This command runs the <b>Create Slack Histogram</b> command to generate a clock histogram for all clocks in the design.
Report All I/O Timings	This command generates a report of all timing paths that start or end at a device port.
Report All Core Timings	This command generates a report of all timing paths that start and end at the device register.

## Console Pane

The **Console** pane is both a message center for the Quartus II TimeQuest Timing Analyzer, and an interactive Tcl. The **Console** pane has two tabs: the **Console** tab and the **History** tab. All messages, such as info and warning messages, appear in this pane. Also, the **Console** tab allows you to enter and run Synopsys Design Constraints and Tcl commands. The **Console** tab shows the Tcl equivalent of all commands that you run in the **Tasks** pane. The **History** tab records all the Synopsys Design Constraints and Tcl commands that are run.

To run the commands located in the **History** tab after the timing netlist has been updated, right-click the command, and click **Rerun**.

You can copy Tcl commands from the **Console** and **History** tabs to easily generate Tcl scripts to perform timing analysis.

## Report Pane

Use the **Report** pane to access all reports generated from the **Tasks** pane, and by any custom report commands. When you select a report in the **Report** pane, the report is shown in the active window in the **View** pane.

If a report is out-of-date with respect to the current constraints, a “?” icon is shown next to the report.

## Constraints

Use the Constraints menu to access commonly used constraints, exceptions, and commands. The following commands are available on the Constraints menu:

- **Create Clock**
- **Create Generated Clock**
- **Set Clock Latency**
- **Set Clock Uncertainty**
- **Set Clock Groups**
- **Remove Clock**

For example, use the **Create Clock** dialog box to create clocks in your design. [Figure 6–39](#) shows the **Create Clock** dialog box.

Figure 6–39. Create Clock Dialog Box

The following commands specify timing exceptions, and are available on the Constraints menu:

- Set False Path
- Set Multicycle Path
- Set Maximum Delay
- Set Minimum Delay

All the dialog boxes used to specify timing constraints or exceptions from commands have an SDC command field. This field contains the SDC command that is run when you click **OK**.

 All commands and constraints created in the Quartus II TimeQuest Timing Analyzer user interface are echoed in the **Console** pane.

The constraints specified with Constraints menu commands are not saved to the current SDC file automatically. You must run the **Write SDC File** command to save your constraints.

The following commands are available on the Constraints menu in the Quartus II TimeQuest Timing Analyzer:

- Generate SDC File from QSF
- Read SDC File
- Write SDC File

The **Generate SDC File from QSF** command runs a Tcl script that converts the Quartus II Classic Timing Analyzer constraints in a QSF file to an SDC file for the Quartus II TimeQuest Timing Analyzer. The file `<current revision>.sdc` is created by this command.

For information about the **Generate SDC File from QSF** command, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The **Generate SDC File from QSF** command attempts to convert all timing constraints and exceptions in the QSF file to their equivalent SDC file constraints. However, not all QSF file constraints are convertible to SDC file constraints. Review the SDC file after it is created to ensure that all constraints have been successfully converted.

The **Read SDC File** command reads the `<current revision>.sdc` file.

When you select the **Write SDC File** command, an up-to-date SDC file that reflects the current state of constraints in the Quartus II TimeQuest Timing Analyzer is generated.

## Name Finder

Use the **Name Finder** dialog box to select the target for any constraints or exceptions in the Quartus II TimeQuest Timing Analyzer GUI. The Name Finder allows you to specify collections, filters, and filter options. The **Collections** field in the **Name Finder** dialog box allows you to specify the type of name to select. To select the type, in the **Collection** list, select the desired collection API including:

- `get_cells`
- `get_clocks`
- `get_keepers`
- `get_nets`
- `get_nodes`
- `get_pins`
- `get_ports`
- `get_registers`

For more information about the various collection APIs, refer to *“Collections”* on page 6–23.

The **Filter** field allows you to filter names based on your own criteria including wildcards characters. You can further refine your results using the following filter options.

- Case-insensitive
- Hierarchical
- Compatibility mode

For more information about the filter options, refer to “Wildcard Assignments and Collections” on page 6–79.

The **Name Finder** dialog box also provides an SDC command field that displays the currently selected name search command. You can copy the value from this field and use it for other constraint target fields. The Name Finder dialog box is shown in [Figure 6–40](#).

**Figure 6–40. Name Finder Dialog Box**

## Target Pane

When using the TimeQuest GUI, you have the ability to split the **View** pane into multiple windows. The splitting feature allows you to display multiple reports in the **View** pane. After splitting the **View** pane, the last active window is updated with any new reports. You can change this behavior by changing the state of each split window. You can do this by clicking on the target circle in the upper right-hand corner (Figure 6-41). Table 6-47 describes the state of each window.

Figure 6-41. Target Pane

State	Description
Partially Filled Red Circle	Indicates that the active window will display any new reports.
Fully Filled Red Circle	Indicates that the window, independent of it being the active window, will display any new reports.
Empty Circle	Indicates that the window will not display any new reports.

Clicking on the circle in the upper right-hand corner of an active window changes the state of the window.

## SDC Editor

The TimeQuest GUI also provides an SDC editor. The SDC editor provides an easy and convenient way to write, edit, and read SDC files directly from the tool. The SDC editor is context sensitive. After an SDC constraint or exception has been entered, a tooltip appears that shows the options and format for the constraint or exception, as shown in Figure 6-42.

Figure 6–42. SDC Editor

```

39
40 # ** Tpd requirements
41 # -----
42
43 # ** Setup/Hold Relationships
44 # -----
45
46 # ** Tsu/Th requirements
47 # -----
48
49
50 # ** Tco/MinTco requirements
51 # -----
52 # create_clock [-add] [-name <clock_name>] -period <value> [-waveform <edge_list>] [<targets>]
53 # -add: Adds clock to a node with an existing clock
54 # -name <clock_name>: Clock name of the created clock
55 # -period <value>: Speed of the clock in terms of clock period
56 # -waveform <edge_list>: List of edge values
57 # <targets>: List or collection of targets
58
59 create_clock

```

The Constraints menu, on the menu bar, allows you to bring up the **Constraints** dialog box. After you have finished entering all required parameters, the SDC is inserted at the current cursor position.

## Conclusion

The Quartus II TimeQuest Timing Analyzer caters to the needs of complex designs, resulting in increased productivity and efficiency through its intuitive user interface, support of industry-standard constraints format, and scripting capabilities. The Quartus II TimeQuest Timing Analyzer is a next-generation timing analysis tool that supports the industry-standard SDC format and allows designers to create, manage, and analyze complex timing constraints, and to perform advanced timing verification.

## Document Revision History

Table 6–48 shows the revision history for this chapter.

<b>Date and Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Updated for the Quartus II software version 7.1, including: <ul style="list-style-type: none"> <li>• Updated organization flow of the Compilation Flow with TimeQuest Guidelines, Timing Analysis Overview, and Specify Design Timing Requirements sections</li> <li>• Added new information on Clock as Data Analysis</li> </ul>	Updated for the Quartus II software version 7.2.
May 2007 v7.1.0	Updated for the Quartus II software version 7.1, including: <ul style="list-style-type: none"> <li>• Added support of <code>report_path</code> in “Timing Reports” on page 6–57</li> <li>• Added <code>report_timing</code> information, especially on page 6-11</li> <li>• Added new information under the following headings:               <ul style="list-style-type: none"> <li>• “Derive Clock Uncertainty” on page 6–40</li> <li>• “report_rskm” on page 6–69</li> <li>• “report_tccs” on page 6–69</li> <li>• “report_path” on page 6–70</li> </ul> </li> <li>• Replaced the “Fast Timing Model Analysis” section with “Multi-Corner Analysis” on page 6–76</li> <li>• Performed general 7.1 updates</li> </ul>	Updated for the Quartus II software version 7.1.
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only. No other changes made to chapter.	—
November 2006 v6.1.0	Updated for the Quartus II software version 6.1, including: <ul style="list-style-type: none"> <li>• New “Getting Started” section, including descriptions of the Create Clock and Create Generated Clock dialog boxes/commands, sections on Specifying Clock Requirements, Specifying Input and Output Port Requirements, and Reporting</li> <li>• SDC Editor</li> <li>• Usability enhancements to the GUI</li> <li>• Updated SDC support</li> <li>• Numerous changes throughout chapter</li> </ul>	Updated for the Quartus II software version 6.1.
July 2006 v6.0.1	Updated for the Quartus II software version 6.0.1: <ul style="list-style-type: none"> <li>• Fixed typo in <code>report_clock_transfers</code> command on page 6-15.</li> </ul>	—
May 2006 v6.0.0	Initial release.	—

## Introduction

The Quartus II TimeQuest Timing Analyzer provides more powerful timing analysis features than the Quartus II Classic Timing Analyzer. This chapter describes the benefits of switching to the Quartus II TimeQuest Timing Analyzer, the differences between the Quartus II TimeQuest and Quartus II Classic Timing Analyzers, and the process you should follow to switch a design from using the Quartus II Classic Timing Analyzer to the Quartus II TimeQuest Timing Analyzer.

### Benefits of Switching to the Quartus II TimeQuest Analyzer

Increasing design complexity requires a timing analysis tool with greater capabilities and flexibility. The Quartus II TimeQuest Timing Analyzer offers the following benefits:

- Industry-standard Synopsys Design Constraint (SDC) support increases productivity.
- Simple, flexible reporting uses industry-standard terminology and makes timing sign-off faster.

For more detailed information about the features and capabilities of the Quartus II TimeQuest Timing Analyzer, refer to the Quartus II TimeQuest Timing Analyzer chapter in volume 3 of the *Quartus II Handbook*.

These features ease constraint and analysis of modern, complex designs. SDC constraints support complex clocking schemes, high-speed interfaces, and more logic. An example includes designs that have multiplexed clocks, regardless of whether they are switched on or off chip. Designs with source-synchronous interfaces, such as DDR memory interfaces, are much simpler to constrain and analyze with the Quartus II TimeQuest Timing Analyzer.

There are three main differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Unlike the Quartus II Classic Timing Analyzer, the Quartus II TimeQuest Timing Analyzer has the following three benefits:

- All clocks are related by default. (Refer to “[Related and Unrelated Clocks](#)” on page 7–13.)
- The default hold multicycle value is zero. (Refer to “[Hold Multicycle](#)” on page 7–24.)

- You must constrain all ports and ripple clocks. (Refer to “Automatic Clock Detection” on page 7-19.)

## Chapter Contents

“Switching to the Quartus II TimeQuest Analyzer” describes the four-step process you should follow to switch a design to the Quartus II TimeQuest Timing Analyzer.

“Differences Between Quartus II TimeQuest and Quartus II Classic Timing Analyzers” on page 7-5 covers terminology, constraints, clocks, hold multicycle, and other differences.

“Timing Assignment Conversion” on page 7-33 is a comprehensive guide to converting Quartus II Classic QSF timing assignments to Quartus II TimeQuest SDC constraints.

“Conversion Utility” on page 7-55 describes a utility that helps you convert Classic QSF timing assignments to Quartus II TimeQuest SDC constraints.

“Notes” on page 7-68 includes notes about support for specific features in the current version of the Quartus II TimeQuest Timing Analyzer.

## Switching to the Quartus II TimeQuest Analyzer

You should use the following process to switch a design from the Quartus II Classic Timing Analyzer to the Quartus II TimeQuest Timing Analyzer. The process is composed of the following steps, which are described in detail in the next sections:

1. Compile your design and perform timing analysis with the Quartus II Classic Timing Analyzer (page 7-2).
2. Create an SDC file that contains timing constraints (page 7-3).
3. Perform timing analysis with the Quartus II TimeQuest Timing Analyzer and examine the reports (page 7-4).
4. Set the default timing analyzer to TimeQuest (page 7-4).

## Compile Your Design

To begin, compile your design with the Quartus® II software. You should run the Quartus II Classic Timing Analyzer during compilation because it is easier to convert your assignments to SDC constraints when you create an SDC file. To run the Quartus II Classic Timing Analyzer in the Quartus II GUI, on the Processing menu, click **Start**, then click **Start**

**Timing Analyzer.** To run the Quartus II Classic Timing Analyzer if you are a command-line user, type `quartus_tan <project>`  at a system command prompt.

## Create an SDC File

The Quartus II TimeQuest Timing Analyzer supports SDC format constraints. If you are familiar with SDC terminology, you can create an SDC file with any text editor and skip to [“Perform Timing Analysis with the Quartus II TimeQuest Timing Analyzer” on page 7–4](#). Name the SDC file `<revision>.sdc` (`<revision>` is the current revision of your project) and save it in your project directory.

Refer to the *SDC and TimeQuest Tcl API Reference Manual* for a TimeQuest SDC command reference.

Alternately, you can use a Quartus II TimeQuest conversion utility to help you convert the timing assignments in an existing QSF file to corresponding SDC constraints.

### Conversion Utility

To run the Quartus II TimeQuest conversion utility, click **Generate SDC file from QSF** on the Constraints menu. You can also run the conversion utility by typing either of the following commands at a system command prompt:

✓ `quartus_tan --qsf2sdc <project name>` 

or

✓ `quartus_sta --qsf2sdc <project name>` 

The SDC file created by the conversion utility is named `<revision>.sdc`.

For information about how to run the Quartus II TimeQuest Timing Analyzer, refer to [“Run the Quartus II TimeQuest Analyzer” on page 7–4](#).

If you use the conversion utility, you must review the SDC file to ensure it is correct and complete, and make changes if necessary. Refer to [“Constraint File Priority” on page 7–10](#) for the recommended way to make changes.

The conversion utility cannot convert some types of Quartus II Classic assignments for the following reasons:

- No corresponding SDC constraint exists

- Multiple SDC constraints are valid, so correct conversion requires knowledge of the intended function of your design

You must manually convert any such assignments based on the guidelines in [“Timing Assignment Conversion”](#) on page 7–33.

## Perform Timing Analysis with the Quartus II TimeQuest Timing Analyzer

When your SDC file is complete, use the reporting capabilities in the Quartus II TimeQuest Timing Analyzer. If you use the Quartus II TimeQuest GUI, double-click any of the reports listed in the **Task** pane. You can also type commands in the Quartus II TimeQuest Tcl shell to generate reports.

You should also review [“Notes”](#) on page 7–68 to ensure the Quartus II TimeQuest Timing Analyzer supports all stages of your design flow.

For complete information about how to use the Quartus II TimeQuest Timing Analyzer, and descriptions of commands and reports, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*, and the *SDC and TimeQuest Tcl API Reference Manual*.

### *Run the Quartus II TimeQuest Analyzer*

If you are using the Quartus II software, to open the Quartus II TimeQuest GUI, on the Tools menu, click **TimeQuest Timing Analyzer**. The Quartus II TimeQuest GUI automatically opens the project you have open in the Quartus II GUI.

If you use the system command prompt to open the Quartus II TimeQuest Timing Analyzer, type `quartus_staw`  to open the Quartus II TimeQuest GUI, or type `quartus_sta -s`  to start the Quartus II TimeQuest Timing Analyzer in Tcl shell mode. Use the **project\_open** command to open your project, or, on the File menu, click **Open Project**.

## Set the Default Timing Analyzer

To use the Quartus II TimeQuest Timing Analyzer as the default timing analyzer for your project, turn on **Use TimeQuest Timing Analyzer during compilation**. In the Quartus II GUI, on the Assignments menu, click **Settings**, then click the **Timing Analysis Settings** category, and select **Use TimeQuest Timing Analyzer during compilation**. You can make the same setting in your project's QSF file with the following Tcl command:

```
set_global_assignment -name \
USE_TIMEQUEST_TIMING_ANALYZER ON
```

This setting directs the Quartus II software to use the Quartus II TimeQuest Timing Analyzer instead of the Quartus II Classic Timing Analyzer.

The setting to make the Quartus II TimeQuest Timing Analyzer the default Timing Analyzer is specific to each project, so you can decide on a per-project basis whether to use the Quartus II TimeQuest Timing Analyzer or the Quartus II Classic Timing Analyzer.

If you want to use the Quartus II Classic Timing Analyzer instead of the Quartus II TimeQuest timing analyzer, ensure **Use Classic Timing Analyzer during compilation** is selected. You can delete the `<revision>.sdc` file, because the Quartus II Classic Timing Analyzer does not use it.

In the Quartus II software, a timing analyzer performs two functions:

- Processing timing constraints and exceptions that affect how your design is placed and routed
- Reporting after place and route is complete so you know whether the design meets timing requirements

Although you can use one timing analyzer to process timing constraints during place and route and the other for reporting, you should use the same timing analyzer for both. The Quartus II Classic Timing Analyzer uses assignments in the QSF file, and the Quartus II TimeQuest Timing Analyzer uses constraints in the SDC file. Any differences between the timing assignments in the two files may cause inconsistent results.

## Differences Between Quartus II TimeQuest and Quartus II Classic Timing Analyzers

The Quartus II TimeQuest Timing Analyzer is different from the Quartus II Classic Timing Analyzer in the following ways:

- Terminology ([page 7-5](#))
- Constraints ([page 7-7](#))
- Clocks ([page 7-13](#))
- Hold Multicycle ([page 7-24](#))
- Fitter Behavior ([page 7-27](#))
- Reporting ([page 7-27](#))
- Scripting API ([page 7-32](#))

### Terminology

This section introduces the industry-standard SDC terminology that the Quartus II TimeQuest Timing Analyzer uses.

For more detailed information about this terminology, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

### Netlist

The Quartus II TimeQuest Timing Analyzer uses SDC naming conventions for netlists. Netlists consist of cells, pins, nets, ports, and clocks.

- Cells are instances of fundamental hardware elements in Altera® FPGAs (such as logic elements, look-up tables, and registers).
- Pins are inputs and outputs of cells.
- Nets are connections between output pins and input pins.
- Ports are top-level module inputs and outputs (device inputs and outputs).
- Clocks are abstract objects outside the netlist.

The terminology of pins and ports is opposite to that of the Quartus II Classic Timing Analyzer. In the Quartus II Classic Timing Analyzer, ports are inputs and outputs of cells, and pins are top-level module inputs and outputs (device inputs and outputs).

Figure 7-1 shows a simple design, and Figure 7-2 shows the Quartus II TimeQuest netlist representation of the design. Netlist elements in Figure 7-2 are labeled to illustrate the SDC terminology.

**Figure 7-1. Sample Design**

Figure 7–2. Quartus II TimeQuest Timing Analyzer Netlist

### Collections

In addition to standard SDC collections, the Quartus II TimeQuest Timing Analyzer supports the following Altera-specific collection types:

- **Keepers**—Non-combinational nodes in a netlist
- **Nodes**—Nodes can be combinational, registers, latches, or ports (device inputs and outputs)
- **Registers**—Registers or latches in the netlist

You can use the **get\_keepers**, **get\_nodes**, or **get\_registers** commands to access these collections.

### Constraints

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers store constraints in different files, support different methods for constraint entry, and prioritize constraints differently. The following sections detail these differences.

#### Constraint Files

The Quartus II TimeQuest Timing Analyzer stores all SDC timing constraints in SDC files. The Quartus II Classic Timing Analyzer stores all timing assignments in your project's Quartus II Settings File (QSF) file. The QSF file contains all your project's assignments and settings except for the Quartus II TimeQuest Timing Analyzer constraints. The

Quartus II TimeQuest Timing Analyzer ignores the timing assignments in your QSF file except when the conversion utility converts Quartus II Quartus II Classic QSF timing assignments to Quartus II TimeQuest SDC constraints. There is no automatic process that keeps timing constraints synchronized between your QSF and SDC files. If you want to keep the constraints synchronized, you must convert them manually.

### *Constraint Entry*

In the Quartus II Classic Timing Analyzer, you enter timing assignments with the Settings dialog box, the Assignment Editor, or with commands in Tcl scripts. The Quartus II TimeQuest Timing Analyzer does not use the Assignment Editor for its constraints, and you cannot use the Assignment Editor to enter SDC constraints. You must use one of the following methods to enter Quartus II TimeQuest constraints:

- Enter constraints at the Tcl prompt in the Quartus II TimeQuest Timing Analyzer
- Enter constraints in an SDC file with a text editor or SDC editor
- Use the constraint entry commands on the Constraints menu in the Quartus II TimeQuest GUI

You can enter timing assignments for the Quartus II Classic Timing Analyzer even if no timing netlist exists for your design. The Quartus II TimeQuest Timing Analyzer requires that a netlist exist for interactive constraint entry. Each Quartus II TimeQuest Timing Analyzer constraint is a Tcl command evaluated in real-time, if entered directly in the Tcl console. As part of this evaluation, the Quartus II TimeQuest Timing Analyzer validates all names. To do this, SDC commands can only be evaluated after a netlist is created. An SDC file can be created at any time using the Quartus II TimeQuest Timing Analyzer or any other text editor, but a netlist is required before an SDC file can be sourced. You must create a timing netlist in the Quartus II TimeQuest Timing Analyzer before you can enter constraints with either of the following interactive methods:

- At the Tcl console of the Quartus II TimeQuest Timing Analyzer
- With commands on the Constraints menu in the Quartus II TimeQuest GUI

If you enter constraints with a text editor separate from the Quartus II TimeQuest Timing Analyzer, no timing netlist is required.

To create a timing netlist in the Quartus II TimeQuest Timing Analyzer, use the **create\_timing\_netlist** command, or double-click **Create Timing Netlist** in the Task pane of the Quartus II TimeQuest GUI.

If you have never compiled your design, and you want to use the Quartus II TimeQuest Timing Analyzer to enter constraints interactively, you must synthesize your design before you create a timing netlist. To synthesize your design, type `quartus_map <project name>` at a system command prompt, or, if you use the Quartus II GUI, ensure that your project is open, then click **Start** on the Processing menu, and click **Start Analysis and Synthesis**.

To create the netlist, open the Quartus II TimeQuest Timing Analyzer. Then, on the Netlist menu, click **Create Timing Netlist...**, select **Post-map**, and click **OK**. Alternately, type `create_timing_netlist -post_map` at the Tcl Console.

### Time Units

Enter time values are in default time units of nanoseconds (ns) with up to three decimal places. Note that the Quartus II TimeQuest Timing Analyzer does not display the default time unit when it displays time values.

You can specify a different default time unit with the **set\_time\_format -unit <default time unit>** command, or specify another unit when you enter a time value, for example, `300ps`.

Specifying time units with the value is not part of the standard SDC format. This is a Quartus II TimeQuest extension.

You can specify clock constraints with period or frequency in the Quartus II TimeQuest Timing Analyzer. For example, you can use either of the following constraints:

- `create_clock -period 10.000`  
(assuming default units and decimal places)
- `create_clock -period "100 MHz"`
- `create_clock -period "10 ns"`

### MegaCore Functions

If you change any MegaCore function settings and regenerate the core after you convert your timing assignments to SDC constraints, you must manually update the SDC constraints or reconvert your assignments. You must update or reconvert, because changes to MegaCore function settings can affect timing assignments embedded in the hardware description language files of the core. The timing assignments are not converted automatically when the core settings change.

You should make a backup copy of your SDC file before reconvertig assignments. If you made changes to the SDC file, you can manually copy the updated MegaCore timing constraints to your SDC file.

### Bus Name Format

In the Quartus II Classic Timing Analyzer, you can make a timing assignment to all bits in a bus with the bus name (or the bus name followed by an asterisk enclosed in square brackets) as the target. For example, to make an assignment to all bits of a bus called address, use `address` or `address [*]` as the target of the assignment.

In the Quartus II TimeQuest Timing Analyzer, you must use the bus name followed by square brackets enclosing an asterisk, like this: `address [*]`.

### Constraint File Priority

The Quartus II TimeQuest Timing Analyzer searches for SDC files with a specific priority, as shown in [Figure 7-3](#).

**Figure 7-3. SDC File Search Order**

If you specify constraints in multiple SDC files, or if you use a single SDC file with a name other than `<revision>.sdc`, you must add the files to your project so the Quartus II TimeQuest Timing Analyzer can find them. If you use the Quartus II software, click **Add/Remove Files in Project** on the Project menu, and add the appropriate SDC files. You can also add SDC files to your project with the following Tcl command in your QSF file, repeated once for each SDC file:

```
set_global_assignment -name SDC_FILE <SDC file name>
```

The Quartus II TimeQuest Timing Analyzer reads constraint files from the files list in the order they are listed, first to last.

If you use an SDC file created by the conversion utility, you should place it before all other SDC files in the list of files. When conflicting constraints apply to the same node, the last constraint has the highest priority. Therefore, SDC files with your additions or changes should be listed after the SDC file created by the conversion utility, so your constraints have higher priority.

Beginning with version 6.1, the Quartus II TimeQuest Timing Analyzer does not run the conversion utility automatically when it cannot find an SDC file according to the priority shown in [Figure 7-3](#). It may prompt you to run the conversion utility from the Constraints menu in the Quartus II TimeQuest GUI.

You must review the SDC file as you would when manually running the conversion utility. Refer to [“Reviewing Conversion Results” on page 7-64](#) for information about how to review the converted constraints.

If no SDC file exists when you run the Quartus II Fitter, and you have turned on **Use TimeQuest Timing Analyzer during compilation**, the Fitter does not create an SDC file automatically, but it attempts to meet a default 1 GHz constraint on all clocks in your design.

### *Constraint Priority*

The Quartus II Classic Timing Analyzer prioritizes assignments based on the specificity of the nodes to which they are assigned. The more specific an assignment is, the higher its priority. The Quartus II TimeQuest Timing Analyzer simplifies these precedence rules. When overlaps occur in the nodes to which the constraints apply, constraints at the bottom of the file take priority over constraints at the top of the file.

As an example, in the Quartus II Classic Timing Analyzer, point-to-point multicycle assignments have higher priority than single point multicycle assignments. The two assignments in [Example 7-1](#) result in a multicycle assignment of 2 between A\_reg and all nodes beginning with B, including B\_reg. The single point assignment does not apply to paths from A\_reg to B\_reg, because the specific point-to-point assignment takes priority over the general single point assignment.

---

**Example 7-1. Quartus II Classic Timing Analyzer Multicycle Assignments**

```
set_instance_assignment -name MULTICYCLE -from A_reg -to B* 2
set_instance_assignment -name MULTICYCLE -to B_reg 3
```

---

[Example 7-2](#) shows SDC versions of the Quartus II Classic Timing Analyzer timing assignments above. However, the Quartus II TimeQuest Timing Analyzer evaluates the constraints top to bottom (regardless of point-to-point or single point), so the path from A\_reg to B\_reg receives a multicycle exception of 3 because it is second in order.

---

**Example 7-2. Quartus II TimeQuest Timing Analyzer Multicycle Exceptions**

```
set_multicycle_path -from [get_keepers A_reg] -to [get_keepers B*] 2
set_multicycle_path -to [get_keepers B_reg] 3
```

---

*Ambiguous Constraints*

Because of new capabilities in the Quartus II TimeQuest Timing Analyzer, some Quartus II Classic assignments can be ambiguous after conversion by the conversion utility. These assignments require manual updating based on your knowledge of your design.

[Figure 7-4](#) shows a ripple clock circuit. The explanation that follows shows an ambiguous constraint for that circuit, and how to edit the constraint to remove the ambiguity in the Quartus II TimeQuest Timing Analyzer.

---

**Figure 7-4. Ripple Clock Circuit**

In the Quartus II Classic Timing Analyzer, the following QSF multicyle assignment from `clk_a` to `clk_b` with a value of 2 applies to paths transferring data from the `clk_a` domain to the `clk_b` domain.

```
set_instance_assignment -name MULTICYCLE -from clk_a -to clk_b 2
```

In [Figure 7-4](#), this assignment applies to the path from `reg_c` to `reg_d`. In the Quartus II TimeQuest Timing Analyzer, the use of the clock node names in the following equivalent multicyle exception is ambiguous.

```
set_multicycle_path -setup -from clk_a -to clk_b 2
```

The exception could apply to the path between `clk_a` and `clk_b`, or it could apply to paths from one ripple clock domain to the other ripple clock domain (`reg_c` to `reg_d`).

The Quartus II TimeQuest exceptions shown in [Example 7-3](#) are not ambiguous because they use collections to explicitly specify the targets of the exception.

---

### **Example 7-3. Unambiguous Quartus II TimeQuest Timing Analyzer Exceptions**

```
# Applies to path from reg_c to reg_d
set_multicycle_path -setup -from [get_clocks clk_a] \
    -to [get_clocks clk_b] 2
# Applies to path from clk_a to clk_b
set_multicycle_path -setup -from [get_registers clk_a] \
    -to [get_registers clk_b] 2
```

---

## **Clocks**

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers detect, analyze, and report clocks differently. The following sections describe these differences.

### *Related and Unrelated Clocks*

In the Quartus II TimeQuest Timing Analyzer, all clocks are related by default, and you must add assignments to indicate unrelated clocks. However, in the Quartus II Classic Timing Analyzer, all base clocks are unrelated by default. All derived clocks of a base clock are related to each other, but are unrelated to other base clocks and their derived clocks.

You can change the default behavior of the Quartus II Classic Timing Analyzer to treat all clocks as related clocks. On the Assignments menu, click **Timing Analysis Settings**. Click **More Settings** and then select **Cut paths between unrelated clock domains**. Ensure that the setting is off.

Figure 7-5 on page 7-14 shows a simple circuit with a path between two clock domains. The Quartus II TimeQuest Timing Analyzer analyzes the path from reg\_a to reg\_b because all clocks are related by default. The Quartus II Classic Timing Analyzer does not analyze the path from reg\_a to reg\_b by default.

**Figure 7-5. Cross Clock Domain Path**

To make clocks unrelated in the Quartus II TimeQuest Timing Analyzer, use the **set\_clock\_groups** command with the **-exclusive** option. For example, the following command makes **clock\_a** and **clock\_b** unrelated, so the Quartus II TimeQuest Timing Analyzer does not analyze paths between the two clock domains.

```
set_clock_groups -exclusive -group {clock_a} -group {clock_b}
```

### *Clock Offset*

In the Quartus II TimeQuest Timing Analyzer, clocks can have non-zero values for the rising edge of the waveform, a feature that the Quartus II Classic Timing Analyzer does not support. To specify an offset for your clock, use the waveform option for the **create\_clock** command to specify the rising and falling edge times, as shown in this example:

```
-waveform {<rising edge time> <falling edge time>}
```

Figure 7-6 shows a clock constraint with an offset in the Quartus II TimeQuest Timing Analyzer GUI.

**Figure 7-6. Create Clock Screen**

Clock offset affects setup and hold relationships. Launch and latch edges are evaluated after offsets are applied. Depending on the offset, the setup relationship can be the offset value, or the difference between the period and offset. You should not use clock offset to emulate latency. You should use the clock latency constraint instead. Refer to “[Offset and Latency Example](#)” on page 7-15 for an example that illustrates the different effects of offset and latency.

### *Clock Latency*

The Quartus II TimeQuest Timing Analyzer does not ignore early clock latency and late clock latency differences when the clock source is the same, as the Quartus II Classic Timing Analyzer does. When you specify latencies, you should take common clock path pessimism into account and use uncertainty to control pessimism differences for clock-to-clock data transfers. Unlike clock offset, clock latency affects skew, and launch and latch edges are evaluated before latencies are applied, so the setup relationship is always equal to the period.

### *Offset and Latency Example*

Figure 7-7 shows a simple register-to-register circuit used to illustrate the different effects of offset and latency. The examples show why you should not use clock offset to emulate clock latency. You should always turn on

the **Enable Clock Latency** option in the Quartus II Classic Timing Analyzer. This option is in the **More Settings** box of the **Timing Settings** dialog box.

**Figure 7-7. Simple Circuit for Offset and Latency Examples**

The period for `clk` is 10 ns, and the period for the PLL output is 10 ns. The PLL compensation value is -2 ns. The network delay from the PLL to `reg_a` equals the network delay from `clk` to `reg_b`. Finally, the delay from `reg_a` to `reg_b` is 3 ns.

**Clock Offset Scenario**

Treat the PLL compensation value of -2 ns as a clock offset of -2 ns with a clock skew of 0 ns. Launch and latch edges are evaluated after offsets are applied, so the setup relationship is 2 ns (Figure 7-8).

**Figure 7-8. Setup Relationship Using Offset**

Equation 1 shows how to calculate the slack value for the path from reg\_a to reg\_b.

$$\begin{aligned}
 (1) \quad \text{slack} &= \text{clock arrival} - \text{data arrival} \\
 \text{slack} &= \text{setup relationship} + \text{clock skew} - \text{reg\_to\_reg delay} \\
 \text{slack} &= 2\text{ns} + 0\text{ns} - 3\text{ns} \\
 \text{slack} &= -1\text{ns}
 \end{aligned}$$

The negative slack requires a multicycle assignment with a value of 2 and a hold multicycle assignment with a value of 1 to correct. With these assignments from reg\_a to reg\_b, the setup relationship is then 12 ns, resulting in a slack of 9 ns.

### Clock Latency Scenario

Treat the PLL compensation value of -2 ns as latency with a clock skew of 2 ns. Because launch and latch edges are evaluated before latencies are applied, the setup relationship is 10 ns (the period of clk and the PLL) (Figure 7-9).

**Figure 7-9. Setup Relationship Using Latency**

Equation 2 shows how to calculate the slack value for the path from reg\_a to reg\_b.

$$\begin{aligned}
 (2) \quad \text{slack} &= \text{clock arrival} - \text{data arrival} \\
 \text{slack} &= \text{setup relationship} + \text{clock skew} - \text{reg\_to\_reg delay} \\
 \text{slack} &= 10\text{ns} + 2\text{ns} - 3\text{ns} \\
 \text{slack} &= 9\text{ns}
 \end{aligned}$$

The slack of 9 ns is identical to the slack computed in the previous example, but because this example uses latency instead of offset, no multicycle assignment is required.

### Clock Uncertainty

The Quartus II Classic Timing Analyzer ignores **Clock Setup Uncertainty** and **Clock Hold Uncertainty** assignments when you specify a setup or hold relationship between two clocks. However, the Quartus II TimeQuest Timing Analyzer does not ignore clock uncertainty when you specify a setup or hold relationship between two clocks. Figures 7–10 and 7–11 illustrate the different behavior between the Quartus II TimeQuest and Quartus II Classic Timing Analyzers.

In both figures, the constraints are identical. There is a 20-ns period for `clk_a` and `clk_b`. There is a setup relationship (a `set_max_delay` exception in the Quartus II TimeQuest Timing Analyzer) of 7 ns from `clk_a` to `clk_b`, and a clock setup uncertainty constraint of 1 ns from `clk_a` to `clk_b`. The actual setup relationship in the Quartus II TimeQuest Timing Analyzer is 1 ns less than in the Quartus II Classic Timing Analyzer because of the way they analyze clock uncertainty.

**Figure 7–10. Quartus II Classic Timing Analyzer Behavior**

**Figure 7–11. Quartus II TimeQuest Timing Analyzer Behavior**

### Derived and Generated Clocks

Generated clocks in the Quartus II TimeQuest Timing Analyzer are different than derived clocks in the Quartus II Classic Timing Analyzer. In the Quartus II Classic Timing Analyzer, the source of a derived clock must be a base clock. However, in the Quartus II TimeQuest Timing Analyzer, the source of a generated clock can be any other clock in the design (including virtual clocks), or any node to which a clock propagates through the clock network. Because generated clocks are related through the clock network, you can specify generated clocks for isolated modules, such as IP, without knowing the details of the clocks outside of the module.

In the Quartus II TimeQuest Timing Analyzer, you can specify generated clocks relative to specific edges and edge shifts of a master clock, a feature that the Quartus II Classic Timing Analyzer does not support.

Figure 7–12 shows a simple ripple clock that you should constrain with generated clocks in the Quartus II TimeQuest Timing Analyzer.

**Figure 7–12. Generated Clocks Circuit**

The Quartus II TimeQuest Timing Analyzer constraints shown in Example 7–4 constrain the clocks in the circuit above. Note that the source of each generated clock can be the input pin of the register itself, not the name of another clock.

#### Example 7–4. Generated Clock Constraints

```
create_clock -period 10 -name clk clk
create_generated_clock -divide_by 2 -source reg_a|CLK -name reg_a reg_a
create_generated_clock -divide_by 2 -source reg_b|CLK -name reg_b reg_b
```

### Automatic Clock Detection

The Quartus II Classic and Quartus II TimeQuest Timing Analyzers identify clock sources of registers that do not have a defined clock source. The Quartus II Classic Timing Analyzer traces back along the clock

network, through registers and logic, until it reaches a top-level port in your design. The Quartus II TimeQuest Timing Analyzer also traces back along the clock network, but it stops at registers.

You can use two SDC commands in the Quartus II TimeQuest Timing Analyzer to automatically detect and create clocks for unconstrained clock sources:

- **derive\_clocks**—creates clocks on sources of clock pins that do not already have at least one clock sourcing the clock pin
- **derive\_pll\_clocks**—identifies PLLs and creates generated clocks on the clock output pins

#### derive\_clocks Command

Figure 7-13 shows a simple circuit with a divide-by-2 register and indicates the clock network delays as A, B, and C. The following explanation describes how the Quartus II Classic and Quartus II TimeQuest Timing Analyzers detect the clocks in Figure 7-13.

**Figure 7-13. Circuit for derive\_clocks Example**

The Quartus II Classic Timing Analyzer detects that `clk` is the clock source for registers `reg_a`, `reg_b`, and `reg_c`. It detects that `clk` is the clock source for `reg_c` because it traces back along the clock network for `reg_c` through `reg_a`, until it finds the `clk` port. The Quartus II Classic Timing Analyzer computes the clock arrival time for `reg_c` as  $A + C$ .

The **derive\_clocks** command in the Quartus II TimeQuest Timing Analyzer creates two base clocks, one on the `clk` port and one on `reg_a`, because the command does not trace through registers on the clock network. The clock arrival time for `reg_c` is  $C$  because the clock starts at `reg_a`.

To make the Quartus II TimeQuest Timing Analyzer compute the same clock arrival time ( $A + C$ ) as the Quartus II Classic Timing Analyzer for **reg\_c**, make the following modifications to the clock constraints created by the **derive\_clocks** command:

- Change the base clock named **reg\_a** to a generated clock
- Make the source the clock pin of **reg\_a** (**reg\_a | clk**) or the port **clk**
- Add a **-divide\_by 2** option

These modifications cause the clock arrival times to **reg\_c** to match between the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer. However, the clock for **reg\_c** is shown as **reg\_a** instead of **clk**, and the launch and latch edges may change for some paths due to the divide-by-2.

You can use the **derive\_clocks** command at the beginning of your design cycle when you do not know all of the clock constraints for your design, but you should not use it during timing sign-off. Instead, you should constrain each clock in your design with the **create\_clock** or **create\_generated\_clocks** commands.

The **derive\_clocks** command detects clocks in your design using the following rules:

1. An input clock port is detected as a clock only if there are no other clocks feeding the destination registers.
  - a. Input clock ports are not detected automatically if they feed only other base clocks.
  - b. If other clocks feed the port's register destinations, the port is assumed to be an enable or data port for a gated clock.
  - c. When no clocks are defined, and multiple clocks feed a destination register, the auto-detected clock is selected arbitrarily.
2. All ripple clocks (registers in a clock path) are detected as clocks automatically using the same rules for input clock ports. If both an input port and a register feed register clock pins, the input port is selected as the clock.

The following examples show how the **derive\_clocks** command detects clocks in the simple circuit, shown in [Figure 7–14](#).

**Figure 7–14. Simple Circuit 1**

- If you do not make any clock settings, and then you run **derive\_clocks**, it detects `a_in` as a clock according to rule 1, because there are no other clocks feeding the register.
- If you create a clock with `b` as its target, and then you run **derive\_clocks**, it does not detect `a_in` as a clock according to rule 1a, because `a_in` feeds only another clock.

The following examples show how the **derive\_clocks** command detects clocks in the simple circuit shown in [Figure 7–15](#).

**Figure 7–15. Simple Circuit 2**

- If you do not make any clock settings and then you run **derive\_clocks**, it selects a clock arbitrarily, according to rule 1c.
- If you create a clock with `a_in` as its target and then you run **derive\_clocks**, it does not detect `b_in` as a clock according to rule 1b, because another clock (`a_in`) feeds the register.

### **derive\_pll\_clocks Command**

The **derive\_pll\_clocks** command names the generated clocks according to the names of the PLL output pins by default, and you cannot change these generated clock names. If you want to use your own clock names, you must use the **create\_generated\_clock** command for each PLL output clock and specify the names with the `-name` option.

If you use the PLL clock-switchover feature, the **derive\_pll\_clocks** command creates additional generated clocks on each output clock pin of the PLL based on the secondary clock input to the PLL. This may require **set\_clock\_groups** or **set\_false\_path** commands to cut the primary and secondary clock outputs. For information about how to make clocks unrelated, refer to [“Related and Unrelated Clocks”](#) on page 7–13.

### Hold Relationship

The Quartus II TimeQuest and Quartus II Classic Timing Analyzers choose the worst-case hold relationship differently. Refer to [Figure 7–16](#) for sample waveforms to illustrate the different effects.

**Figure 7–16. Worst-Case Hold**

The Quartus II Classic Timing Analyzer first identifies the worst-case setup relationship. The worst-case setup relationship is **Setup B**. Then the Quartus II Classic Timing Analyzer chooses the worst-case hold relationship (Hold Check B1 or Hold Check B2) for that specific setup relationship, Setup B. The Quartus II Classic Timing Analyzer chooses Hold Check B2 for the worst-case hold relationship.

However, the Quartus II TimeQuest Timing Analyzer calculates worst-case hold relationships for all possible setup relationships and chooses the absolute worst-case hold relationship. The Quartus II TimeQuest Timing Analyzer checks two hold relationships for every setup relationship:

- Data launched by the current launch edge not captured by the previous latch edge (Hold Check A1 and Hold Check B1)
- Data launched by the next launch edge not captured by the current latch edge (Hold Check A2 and Hold Check B2)

The Quartus II TimeQuest Timing Analyzer chooses Hold Check A2 as the absolute worst-case hold relationship.

### Clock Objects

The Quartus II Classic Timing Analyzer treats nodes with clock settings assigned to them as special objects in the timing netlist. Any node in the timing netlist with a clock setting is treated as a clock object, regardless of its actual type, such as a register. When a register has a clock setting

assigned to it, the Quartus II Classic Timing Analyzer does not analyze register-to-register paths beginning or ending at that register. Figure 7-17 shows a circuit that illustrates this situation.

**Figure 7-17. Clock Objects**

With no clock assignments on any of the registers, the Quartus II Classic Timing Analyzer analyzes timing on the path from `reg_a` to `reg_b`, and from `reg_c` to `reg_d`. If you make a clock setting assignment to `reg_b`, `reg_b` is no longer considered a register node in the netlist, and the path from `reg_a` to `reg_b` is no longer analyzed.

In the Quartus II TimeQuest Timing Analyzer, clocks are abstract objects that are associated with nodes in the timing netlist. The Quartus II TimeQuest Timing Analyzer analyzes the path from `reg_a` to `reg_b` even if there is a clock assigned to `reg_b`.

## Hold Multicycle

The hold multicycle value numbering scheme is different in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Also, you can choose between two values for the default hold multicycle value in the Quartus II Classic Timing Analyzer but you cannot change the default value in the Quartus II TimeQuest Timing Analyzer. The hold multicycle value specifies which clock edge is used for hold analysis when you change the latch edge with a multicycle assignment.

In the Quartus II Classic Timing Analyzer, the hold multicycle value is based on 1, and is the number of clock cycles away from the setup edge. In the Quartus II TimeQuest Timing Analyzer, the hold multicycle value is based on zero, and is the number of clock cycles away from the default hold edge. In the Quartus II TimeQuest Timing Analyzer, the default hold edge is one edge before or after the setup edges. Subtract 1 from any hold multicycle value in the Quartus II Classic Timing Analyzer to compute the equivalent value for the Quartus II TimeQuest Timing Analyzer.

In the Quartus II Classic Timing Analyzer, you can set the default value of the hold multicycle assignment to **One** or **Same as Multicycle**. The default value applies to any multicycle assignment in your design that does not also have a multicycle hold assignment. Figure 7-18 illustrates the difference between **One** and **Same as Multicycle** for a multicycle assignment of 2 using the Quartus II Classic Timing Analyzer.

**Figure 7-18. Difference Between One and Same As Multicycle**

If the default value is **One**, the Quartus II Classic Timing Analyzer uses the clock edge one before the setup edge for hold analysis. If the default value is **Same as Multicycle**, the Quartus II Classic Timing Analyzer uses the clock edge that is *<value of multicycle assignment>* edges back from the setup edge.

Figure 7-19 shows simple waveforms for a cross-clock domain transfer with the indicated setup and hold edges.

**Figure 7-19. First Relationship Example**

In the Quartus II TimeQuest Timing Analyzer, only a multicycle exception of 2 is required to constrain the design for the indicated setup and hold relationships.

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **One**, only a multicycle assignment of 2 is required to constrain the design.

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **Same as Multicycle**, you must make two assignments to constrain the design:

- A multicycle assignment of 2
- A hold multicycle assignment of 1 to override the default value

Figure 7–20 shows simple waveforms for a different cross-clock domain transfer with indicated setup and hold edges. The following explanation shows what exceptions to apply to achieve the desired setup and hold relationships.

**Figure 7–20. Second Relationship Example**

In the Quartus II TimeQuest Timing Analyzer, you must use the following two exceptions:

- A multicycle exception of 2
- A hold multicycle exception of 1, because the hold edge is one edge behind the default hold edge, which is one edge after the setup edge.

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **One**, you must make two assignments to constrain the design:

- A multicycle assignment of 2
- A hold multicycle assignment of 2 to override the default value

In the Quartus II Classic Timing Analyzer, if the **Default Hold Multicycle** value is **Same as Multicycle**, only a multicycle assignment of 2 is required to constrain the design.

You should always add a hold multicycle assignment for every multicycle assignment to ensure the correct exceptions are applied regardless of the timing analyzer you use, or, for the Quartus II Classic Timing Analyzer, the **Default Hold Multicycle** setting.

### Fitter Behavior

The behavior for one value of the **Optimize hold time** Fitter assignment differs between the Quartus II TimeQuest Timing Analyzer and the Quartus II Classic Timing Analyzer. When you set the Quartus II TimeQuest Timing Analyzer as the default timing analyzer, the **I/O Paths and Minimum TPD Paths** value directs the Fitter to optimize all hold time paths, which has the same affect as the **All Paths** value.

#### *Fitter Performance*

If you use the Quartus II TimeQuest Timing Analyzer as your default timing analyzer, the Fitter memory use and compilation time may increase. However, the timing analysis time may decrease.

### Reporting

The Quartus II TimeQuest Timing Analyzer provides a more flexible and powerful interface for reporting timing analysis results than the Quartus II Classic Timing Analyzer. Although the interface and constraints are more flexible and powerful, both analyzers use the same device timing models, except for device families that support rise/fall analysis. The Quartus II Classic Timing Analyzer does not support rise/fall analysis, but the Quartus II TimeQuest Timing Analyzer does. Therefore, you may see slightly different delays on identical paths in device families that support rise/fall analysis if you analyze timing in both analyzers.

This means that both analyzers report identical delays along identically constrained paths in your design. The Quartus II TimeQuest Timing Analyzer allows you to constrain some paths that you could not constrain with the Quartus II Classic Timing Analyzer. Differently constrained paths result in different reported values, but for identical paths in your design that are constrained the same way, the delays are exactly the same. Both timing analyzers use the same timing models.

For information about reporting with the Quartus II TimeQuest Timing Analyzer, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

### Paths and Pairs

In reporting, the most significant difference between the two analyzers is that the Quartus II TimeQuest Timing Analyzer reports paths, while the Quartus II Classic Timing Analyzer reports pairs. Path reporting means that the analyzer separately reports every path between two registers. Pair reporting means that the analyzer reports only the worst-case path between two registers. One benefit of path reporting over pair reporting is that you can more easily identify common points in failing paths that may be good targets for optimization.

If your design does not meet timing constraints, this reporting difference can give the impression that there are many more timing failures when you use the Quartus II TimeQuest Timing Analyzer. Figure 7-21 shows a sample circuit followed by a description of the differences between path and pair reporting.

**Figure 7-21. Failing Paths**

There is an 8-ns period constraint on `clk`, resulting in two paths that fail timing: `regA → C → regB` and `regA → D → regB`. The Quartus II Classic Timing Analyzer reports only worst-case path `regA → C → regB`. The Quartus II TimeQuest Timing Analyzer reports both failing paths `regA → C → regB` and `regA → D → regB`. It also reports path `regA → E → regB` with positive slack.

### Default Reports

The Quartus II TimeQuest Timing Analyzer generates only a small number of reports by default, as compared to the Quartus II Classic Timing Analyzer, which generates every report by default. With the Quartus II TimeQuest Timing Analyzer, you generate desired reports on demand.

To learn how to create custom reports, refer to the *Quartus II Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

### Netlist Names

The Quartus II Classic Timing Analyzer uses register names in reporting, but the Quartus II TimeQuest Timing Analyzer uses register pin names (with the exception of port names of the top-level module). Buried nodes or register names are used when necessary.

[Example 7-5](#) shows how register names are used in Quartus II Classic Timing Analyzer reports.

---

#### **Example 7-5. Netlist Names in the Quartus II Classic Timing Analyzer**

```
Info: + Shortest register to register delay is 0.538 ns
Info: 1: + IC(0.000 ns) + CELL(0.000 ns) = 0.000 ns; Loc. =
LCFF_X1_Y5_N1;
Fanout = 1; REG Node = 'inst'
Info: 2: + IC(0.305 ns) + CELL(0.149 ns) = 0.454 ns; Loc. =
LCCOMB_X1_Y5_N20; Fanout = 1; COMB Node = 'inst3~feeder'
Info: 3: + IC(0.000 ns) + CELL(0.084 ns) = 0.538 ns; Loc. =
LCFF_X1_Y5_N21; Fanout = 1; REG Node = 'inst3'
Info: Total cell delay = 0.233 ns ( 43.31 % )
Info: Total interconnect delay = 0.305 ns ( 56.69 % )
```

---

[Example 7-6](#) shows the same information as presented in a Quartus II TimeQuest Timing Analyzer report. In this example, register pin names are used in place of register names.

---

#### **Example 7-6. Netlist Names in the Quartus II TimeQuest Timing Analyzer**

```

Info:      4.326      0.084 RR  CELL  inst3
```

---

### Non-Integer Clock Periods

In some cases when related clock periods are not integer multiples of each other, a lack of precision in clock period definition in the Quartus II TimeQuest Timing Analyzer can result in reported setup or hold relationships of a few picoseconds. In addition, launch and latch times for the relationships can be very large. If you experience this, use the `set_max_delay` and `set_min_delay` exceptions to specify the correct

relationships. The Quartus II Classic Timing Analyzer can maintain additional information about clock frequency that mitigates the lack of precision in clock period definition.

When the clock period cannot be expressed as an integer in terms of picoseconds, then you have the problem detailed in [Figure 7-22](#). This figure shows two clocks: `clk_a` has a 10 ns period, and `clk_b` has a 6.667 ns period.

**Figure 7-22. Very Small Setup Relationship**

There is a 1 ps setup relationship at 20 ns because you cannot specify the 6.667 ns period beyond picosecond precision. You should apply the maximum and minimum delay exceptions shown in [Example 7-7](#) between the two clocks to specify the correct relationships.

**Example 7-7. Minimum and Maximum Delay Exceptions**

```
set_max_delay -from [get_clocks clk_a] -to [get_clocks clk_b] 3.333
set_min_delay -from [get_clocks clk_a] -to [get_clocks clk_b] 0
```

*Other Features*

The Quartus II TimeQuest Timing Analyzer reports time values without units. By default, the units are nanoseconds, and three decimal places are displayed. You can change the default time unit and decimal places with the `set_time_format` command.

When you use the Quartus II TimeQuest Timing Analyzer in a Tcl shell, output is ASCII-formatted, and columns are aligned for easy reading on 80-column consoles. [Example 7-8](#) shows sample output from a `report_timing` command from the Quartus II TimeQuest Timing Analyzer.

**Example 7-8. ASCII-Formatted Quartus II TimeQuest Timing Analyzer Report**

```

## Scripting API

In versions of the Quartus II software earlier than 6.0, the `::quartus::project` Tcl package contained the following SDC-like commands for making timing assignments:

- `create_base_clock`
- `create_relative_clock`
- `get_clocks`
- `set_clock_latency`
- `set_clock_uncertainty`
- `set_input_delay`
- `set_multicycle_assignment`
- `set_output_delay`
- `set_timing_cut_assignment`

These commands are not SDC-compliant. Beginning with version 6.0, these commands are in a new package called

`::quartus::timing_assignment`. To ensure backward compatibility with existing Tcl scripts, the `::quartus::timing_assignment` package is loaded by default in the following executables:

- `quartus`
- `quartus_sh`
- `quartus_cdb`
- `quartus_sim`
- `quartus_stp`
- `quartus_tan`

The `::quartus::timing_assignment` package is not loaded by default in the `quartus_sta` executable. The `::quartus::sdc` Tcl package includes SDC-compliant versions of the commands listed above. That package is available only in the `quartus_sta` executable, and it is loaded by default.

## Timing Assignment Conversion

This section describes Quartus II Classic QSF timing assignments and their equivalent Quartus II TimeQuest constraints. You can convert many Quartus II Classic timing assignments to SDC constraints. Some Quartus II Classic timing assignments can be converted to two different SDC constraints, and you must understand the intended functionality of the design to make an appropriate conversion. You cannot convert some Quartus II Classic timing assignments because there is no equivalent SDC constraint.

This section includes the following topics, arranged alphabetically:

Clock Enable Multicycle .....	7-38
Clock Latency .....	7-34
Clock Settings .....	7-37
Clock Uncertainty .....	7-34
Cut Timing Path .....	7-52
Default Required $f_{MAX}$ Assignment .....	7-35
Hold Relationship .....	7-34
Input and Output Delay .....	7-39
Inverted Clock .....	7-35
Maximum Clock Arrival Skew .....	7-53
Maximum Data Arrival Skew .....	7-53
Maximum Delay .....	7-52
Minimum Delay .....	7-52
Minimum $t_{CO}$ Requirement .....	7-48
Minimum $t_{PD}$ Requirement .....	7-51
Multicycle .....	7-37
Not a Clock .....	7-35
Setup Relationship .....	7-33
$t_{CO}$ Requirement .....	7-45
$t_H$ Requirement .....	7-43
$t_{PD}$ Requirement .....	7-50
$t_{SU}$ Requirement .....	7-40
Virtual Clock Reference .....	7-36

### Setup Relationship

The **Setup Relationship** assignment overrides the setup relationship between two clocks. By default, the Quartus II Classic Timing Analyzer automatically calculates the setup relationship based on your clock settings. The QSF variable for the **Setup Relationship** assignment is `SETUP_RELATIONSHIP`. In the Quartus II TimeQuest Timing Analyzer, use the `set_max_delay` command to specify the maximum setup relationship for a path.

The setup relationship value is the time between latch and launch edges before the Quartus II TimeQuest Timing Analyzer accounts for clock latency, source  $\mu t_{CO}$ , or destination  $\mu t_{SU}$ .

## Hold Relationship

The **Hold Relationship** assignment overrides the hold relationship between two clocks. By default, the Quartus II Classic Timing Analyzer automatically calculates the hold relationship based on your clock settings. The QSF variable for the **Hold Relationship** assignment is HOLD\_RELATIONSHIP. In the Quartus II TimeQuest Timing Analyzer, use the **set\_min\_delay** command to specify the minimum hold relationship for a path.

## Clock Latency

Table 7-1 shows the equivalent SDC constraints for each of these Quartus II Classic assignments.

<i>Table 7-1. Quartus II Classic and SDC Equivalent Constraints</i>		
Quartus II Classic Timing Assignment		SDC Constraint
Assignment Name	QSF Variable	
Early Clock Latency	EARLY_CLOCK_LATENCY	set_clock_latency -source -late
Late Clock Latency	LATE_CLOCK_LATENCY	set_clock_latency -source -early

For more information about clock latency support in the Quartus II TimeQuest Timing Analyzer, refer to “[Clock Latency](#)” on page 7-15.

## Clock Uncertainty

This section describes the conversion for the following Quartus II Classic assignments:

- Clock Setup Uncertainty
- Clock Hold Uncertainty

Table 7-2 shows the equivalent SDC constraints for each of these Quartus II Classic assignments.

Quartus II Classic Timing Assignment		SDC Constraint
Assignment Name	QSF Variable	
Clock Setup Uncertainty	CLOCK_SETUP_UNCERTAINTY	set_clock_uncertainty -setup
Clock Hold Uncertainty	CLOCK_HOLD_UNCERTAINTY	set_clock_uncertainty -hold

## Inverted Clock

The Quartus II Classic Timing Analyzer detects inverted clocks automatically when the clock inversion occurs at the input of the LCELL that contains the register specified in the assignment. You must make an **Inverted Clock** assignment in all other situations for Quartus II Classic Timing Analyzer analysis. The QSF variable for the **Inverted Clock** assignment is INVERTED\_CLOCK. The Quartus II TimeQuest Timing Analyzer detects inverted clocks automatically, regardless of the type of inversion circuit, in designs that target device families that support unateness: Stratix® II, Cyclone® II, and HardCopy® II. For designs that target any other device family, you must create a generated clock with the `-invert` option on the output of the cell that inverts the clock.

For more information about unateness, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

## Not a Clock

The **Not a Clock** assignment directs the Quartus II Classic Timing Analyzer that the specified node is not a clock source when it would normally be detected as a clock because of a global  $f_{MAX}$  requirement. The QSF variable for the **Not a Clock** assignment is NOT\_A\_CLOCK. This assignment is not supported in the Quartus II TimeQuest Timing Analyzer and there is no equivalent constraint. Appropriate clock constraints are created in the Quartus II TimeQuest Timing Analyzer only.

## Default Required $f_{MAX}$ Assignment

The **Default Required  $f_{MAX}$**  assignment allows you to specify an  $f_{MAX}$  requirement for the Quartus II Classic Timing Analyzer for all unconstrained clocks in your design. The QSF variable for the **Default Required  $f_{MAX}$**  assignment is FMAX\_REQUIREMENT. You can use the

`derive_clocks` command to create clocks on sources of clock pins in your design that do not already have clocks assigned to them. You should constrain each individual clock in your design with the `create_clock` or `create_generated_clock` command, not the `derive_clocks` command. Refer to “Automatic Clock Detection” on page 7-19 to learn why you should constrain individual clocks in your design.

## Virtual Clock Reference

The **Virtual Clock Reference** assignment allows you to define timing characteristics of a reference clock outside the FPGA. The QSF variable for the **Virtual Clock Reference** assignment is `VIRTUAL_CLOCK_REFERENCE`. The Quartus II TimeQuest Timing Analyzer supports virtual clocks by default, while the Quartus II Classic Timing Analyzer requires the **Virtual Clock Reference** assignment to indicate that a clock setting is for a virtual clock. To create a virtual clock in the Quartus II TimeQuest Timing Analyzer, use the `create_clock` or `create_generated_clock` commands with the `-name` option and no targets.

Figure 7-23 shows a simple circuit that requires a virtual clock, and the following example shows how to constrain the circuit. The circuit shows data transfer between an Altera FPGA and another device, and the clocks for the two devices are not related. You can constrain the path with an output delay assignment, but that assignment requires a virtual clock that defines the clock characteristics of the destination device.

**Figure 7-23. Virtual Clock Sample Circuit**

Assume the circuit has the following assignments in the Quartus II Classic Timing Analyzer:

- Clock period of 10 ns on `system_clk` (clock for the Altera FPGA)
- Clock period of 8 ns on `virt_clk` (clock for the other device)
- Virtual Clock Reference setting for `virt_clk` is on (indicates that `virt_clk` is a virtual clock)

- Output Maximum Delay of 5 ns on dataout with respect to virt\_clk (constrains the path between the two devices)

The SDC commands shown in [Example 7–9](#) constrain the circuit the same way.

---

### Example 7–9. SDC Constraints

```
# Clock for the Altera FPGA
create_clock -period 10 -name system_clk [get_ports system_clk]
# Virtual clock for the other device, with no targets
create_clock -period 8 -name virt_clk
# Constrains the path between the two devices
set_output_delay -clock virt_clk 5 [get_ports dataout]
```

---

## Clock Settings

The Quartus II Classic Timing Analyzer includes a variety of assignments to describe clock settings. These include duty cycle,  $f_{MAX}$ , offset, and others. In the Quartus II TimeQuest Timing Analyzer, use the `create_clock` and `create_generated_clock` commands to constrain clocks.

## Multicycle

[Table 7–3](#) shows the equivalent SDC exceptions for each of these Quartus II Classic Timing Analyzer timing assignments.

<i>Table 7–3. Quartus II Classic and SDC Equivalent Exceptions</i>		
Quartus II Classic Timing Assignment		SDC Exception
Assignment Name	QSF Variable	
Multicycle (1)	MULTICYCLE	set_multicycle_path -setup -end
Source Multicycle (2)	SRC_MULTICYCLE	set_multicycle_path -setup -start
Multicycle Hold (3)	HOLD_MULTICYCLE	set_multicycle_path -hold -end
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	set_multicycle_path -hold -start

#### Notes to [Table 7–3](#):

- (1) A multicycle assignment is also known as a “destination multicycle setup” assignment.
- (2) A source multicycle assignment is also known as a “source multicycle setup” assignment.
- (3) A multicycle hold is also known as a “destination multicycle hold” assignment.

The default value and numbering scheme for the hold multicycle value is different in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers. Refer to [“Hold Multicycle” on page 7–24](#) for more information

about the difference between the default value and numbering scheme for the hold multicycle value in the Quartus II Classic and Quartus II TimeQuest Timing Analyzers.

For more information about how to convert the hold multicycle value, see the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

## Clock Enable Multicycle

The Quartus II Classic Timing Analyzer supports the following clock enable multicycle assignments. Corresponding types of multicycle assignments are applied to all registers enabled by the targets of the specified clock.

- Clock Enable Multicycle
- Clock Enable Source Multicycle
- Clock Enable Multicycle Hold
- Clock Enable Source Multicycle Hold

The Quartus II TimeQuest Timing Analyzer supports clock-enabled multicycle constraints with the **get\_fanouts** command. Use the **get\_fanouts** command to create a collection of nodes that have a common source signal, such as a clock enable.

## I/O Constraints

FPGA I/O timing assignments have typically been made with FPGA-centric  $t_{SU}$  and  $t_{CO}$  requirements for the Quartus II Classic Timing Analyzer. However, the Quartus II Classic Timing Analyzer also supports input and output delay assignments to accommodate industry-standard, system-centric timing constraints. Where possible, you should use system-centric constraints to constrain your designs for the Quartus II TimeQuest Timing Analyzer. [Table 7-4](#) includes Quartus II Classic I/O assignments, the equivalent FPGA-centric SDC constraints, and recommended system-centric SDC constraints.

For setup checks ( $t_{SU}$  and  $t_{CO}$ ), *<latch – launch>* equals the clock period for same-clock transfers. For hold checks ( $t_H$  and Minimum  $t_{CO}$ ), *<latch – launch>* equals 0 for same clock transfers. Conversions from Quartus II Classic assignments to `set_input_delay` and `set_output_delay` constraints work well only when the source and destination registers' clocks are the same (same clock and polarity). If the source and

destination registers' clocks are different, the conversion may not be straightforward and you should take extra care when converting to `set_input_delay` and `set_output_delay` constraints.

**Table 7-4. Quartus II Classic and Quartus II TimeQuest Timing Analyzers Equivalent I/O Constraints**

Classic	FPGA-centric SDC	System-centric SDC
$t_{SU}$ Requirement	<code>set_max_delay &lt;<math>t_{SU}</math> requirement&gt;</code>	<code>set_input_delay -max &lt;latch – launch – <math>t_{SU}</math> requirement&gt;</code>
$t_H$ Requirement	<code>set_min_delay – &lt;<math>t_H</math> requirement&gt; (1)</code>	<code>set_input_delay -min &lt;latch – launch + <math>t_H</math> requirement&gt;</code>
$t_{CO}$ Requirement	<code>set_max_delay &lt;<math>t_{CO}</math> requirement&gt;</code>	<code>set_output_delay -max &lt;latch – launch – <math>t_{CO}</math> requirement&gt;</code>
Minimum $t_{CO}$ Requirement	<code>set_min_delay &lt;minimum <math>t_{CO}</math> requirement&gt;</code>	<code>set_output_delay -min &lt;latch – launch – minimum <math>t_{CO}</math> requirement&gt;</code>
$t_{PD}$ Requirement	<code>set_max_delay &lt;<math>t_{PD}</math> requirement&gt;</code>	(2)
Minimum $t_{PD}$ Requirement	<code>set_min_delay &lt;minimum <math>t_{PD}</math> requirement&gt;</code>	(2)

**Notes to Table 7-4:**

- (1) Refer to “ $t_H$  Requirement” on page 7-43 for an explanation about why this exception uses the negative  $t_H$  requirement.
- (2) The input and output delays can be used for  $t_{PD}$  paths, such that they will be analyzed as a system  $f_{MAX}$  path. This is a feature unique to the Quartus II TimeQuest Timing Analyzer.

## Input and Output Delay

Table 7-5 shows the equivalent SDC exceptions for each of these Quartus II Classic Timing Analyzer timing assignments.

**Table 7-5. Quartus II Classic and SDC Equivalent Exceptions**

Quartus II Classic Timing Assignment		SDC Exception
Assignment Name	QSF Variable	
Input Maximum Delay	INPUT_MAX_DELAY	<code>set_input_delay -max</code>
Input Minimum Delay	INPUT_MIN_DELAY	<code>set_input_delay -min</code>
Output Maximum Delay	OUTPUT_MAX_DELAY	<code>set_output_delay -max</code>
Output Minimum Delay	OUTPUT_MIN_DELAY	<code>set_output_delay -min</code>

In some circumstances, you may receive the following warning message when you update the SDC netlist:

```
Warning: For set_input_delay/set_output_delay, port
"<port>" does not have delay for flag (<rise|fall>,
<min|max>)
```

This warning occurs whenever port constraints have maximum or minimum delay assignments, but not both. In the Quartus II Classic Timing Analyzer, device inputs can have **Input Maximum Delay** assignments, **Input Minimum Delay** assignments, or both, and device outputs can have **Output Maximum Delay** assignments, **Output Minimum Delay** assignments, or both.

To avoid receiving the warning, your SDC file must specify both the `-max` and `-min` options for each port, or specify neither. If a device I/O in your design includes both the maximum and minimum delay assignments in the Quartus II Classic Timing Analyzer, the conversion utility converts both, and no warning appears about that device I/O. If a device I/O has only maximum or minimum delay assignments in the Quartus II Classic Timing Analyzer, you have the following options:

- Add the missing minimum or maximum delay assignment to the device I/O before performing the conversion.
- Modify the SDC constraint after the conversion to add appropriate `-max` or `-min` values.
- Modify the SDC constraint to remove the `-max` or `-min` option so the value is used for both by default.

## **t<sub>SU</sub> Requirement**

The **t<sub>SU</sub> Requirement** assignment specifies the maximum acceptable clock setup time for the input (data) pin. The QSF variable for the **t<sub>SU</sub> Requirement** assignment is `TSU_REQUIREMENT`. You can convert the **t<sub>SU</sub> Requirement** assignment to the `set_max_delay` command or the `set_input_delay` command with the `-max` option. The delay value for the `set_input_delay` command is `<latch -launch -tSU requirement>`. Refer to the labeled paths in [Figure 7-24](#) to understand the names in Equations 3 and 4.

Figure 7–24. Path Names

Equation 3 shows the derivation of this conversion.

$$\begin{aligned}
 (3) \quad & \text{required} - \text{arrival} > 0 \\
 & \text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} - \text{dst.utsu} \\
 & \text{arrival} = \text{launch} + \text{board.srclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} + \text{dst.in} \\
 \\
 & \text{input\_delay} = \text{board.srclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} - \text{board.dstclk} \\
 \\
 & \text{required} = \text{latch} + \text{dst.clk} - \text{dst.utsu} \\
 & \text{arrival} = \text{launch} + \text{input\_delay} + \text{dst.in} \\
 & (\text{latch} + \text{dst.clk} - \text{dst.utsu}) - (\text{launch} + \text{input\_delay} + \text{dst.in}) > 0 \\
 \\
 & t_{\text{su}} \text{ requirement} - \text{actual } t_{\text{su}} > 0 \\
 & \text{actual } t_{\text{su}} = \text{dst.in} + \text{dst.utsu} - \text{dst.clk} \\
 & t_{\text{su}} \text{ requirement} - (\text{dst.in} + \text{dst.utsu} - \text{dst.clk}) > 0 \\
 \\
 & t_{\text{su}} \text{ requirement} = \text{latch} - \text{launch} - \text{input\_delay} \\
 & \text{input\_delay} = \text{latch} - \text{launch} - t_{\text{su}} \text{ requirement}
 \end{aligned}$$

The delay value is the difference between the period of the clock source of the register and the  $t_{SU}$  **Requirement** value, as shown in [Figure 7-25](#).

**Figure 7-25.  $t_{SU}$  Requirement**

The delay value for the `set_max_delay` command is the  $t_{SU}$  **Requirement** value. [Equation 4](#) shows the derivation of this conversion.

$$\begin{aligned}
 (4) \quad & \text{required} - \text{arrival} > 0 \\
 & \text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} - \text{dst.utsu} \\
 & \text{arrival} = \text{launch} + \text{board.srclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{sretodst} + \text{dst.in} \\
 & \text{max\_delay} = \text{latch} + \text{board.dstclk} + - \text{launch} - \text{board.srclk} - \text{src.clk} - \text{src.out} - \text{sretodst} \\
 \\
 & \text{required} = \text{max\_delay} + \text{dst.clk} - \text{dst.utsu} \\
 & \text{arrival} = \text{dst.in} \\
 & (\text{max\_delay} + \text{dst.clk} - \text{dst.utsu}) - (\text{dst.in}) > 0 \\
 \\
 & t_{su} \text{ requirement} - t_{su} > 0 \\
 & \text{actual } t_{su} = \text{dst.in} + \text{dst.utsu} - \text{dst.clk} \\
 & t_{su} \text{ requirement} - (\text{dst.in} + \text{dst.utsu} - \text{dst.clk}) > 0 \\
 \\
 & \text{set\_max\_delay} = t_{su} \text{ requirement}
 \end{aligned}$$

Table 7-6 shows the different ways you can make  $t_{SU}$  assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the `set_max_delay` exception.

$t_{SU}$ Requirement Options	<code>set_max_delay</code> Options
-to <pin>	-from [get_ports <pin>] -to [get_registers *]
-to <clock>	-from [get_ports *] -to [get_clocks <clock>]
-to <register>	-from [get_ports *] -to [get_registers <register>]
-from <pin> -to <register>	-from [get_ports <pin>] -to [get_registers <register>]
-from <clock> -to <pin>	-from [get_ports <pin>] -to [get_clocks <clock>] (1)

**Notes to Table 7-6:**

- (1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, -to <pin>. If the pin feeds registers clocked by different clocks, use `set_input_delay` to constrain the paths properly.

To convert a global  $t_{SU}$  assignment to an equivalent SDC exception, use the command shown in Example 7-10.

**Example 7-10. Converting a Global  $t_{SU}$  Assignment to an Equivalent SDC Exception**

```
set_max_delay -from [all_inputs] -to [all_registers] < $t_{SU}$  value>
```

## $t_H$ Requirement

The  $t_H$  Requirement specifies the maximum acceptable clock hold time for the input (data) pin. The QSF variable for the  $t_H$  Requirement assignment is TH\_REQUIREMENT. You can convert the  $t_H$  Requirement assignment to the `set_min_delay` command, or the `set_input_delay` command with the `-min` option. The delay value for the `set_input_delay` command is  $\langle \text{latch} - \text{launch} + t_H \text{ requirement} \rangle$ . Refer to the labeled paths in Figure 7-26 to understand the names in Equations 5 and 6.

**Figure 7-26. Path Names**

Equation 5 shows the derivation of this calculation.

$$\begin{aligned}
 (5) \quad & \text{arrival} - \text{required} > 0 \\
 & \text{arrival} = \text{launch} + \text{board.srclk} + \text{src.clk} + \text{src.utco} + \text{src.out} + \text{srctodst} + \text{dst.in} \\
 & \text{required} = \text{latch} + \text{board.dstclk} + \text{dst.clk} + \text{dst.uth} \\
 & \text{input\_delay} = \text{board.srclk} + \text{src.clk} + \text{srctcu} + \text{src.out} + \text{srctodst} - \text{board.dstclk}
 \end{aligned}$$

$$\begin{aligned}
 & \text{arrival} = \text{launch} + \text{input\_delay} + \text{dst.in} \\
 & \text{required} = \text{latch} + \text{dst.clk} + \text{dst.uth} \\
 & (\text{launch} + \text{input\_delay} + \text{dst.in}) - (\text{latch} + \text{dst.clk} + \text{dst.uth}) > 0
 \end{aligned}$$

$$\begin{aligned}
 & t_H \text{ requirement} - \text{actual } t_H > 0 \\
 & \text{actual } t_H = \text{dst.clk} + \text{dst.uth} - \text{dst.in} \\
 & t_H \text{ requirement} - (\text{dst.clk} + \text{dst.uth} - \text{dst.in}) > 0
 \end{aligned}$$

$$\begin{aligned}
 & t_H \text{ requirement} = \text{launch} - \text{latch} + \text{input\_delay} \\
 & \text{input\_delay} = \text{latch} - \text{launch} + t_H \text{ requirement}
 \end{aligned}$$

The delay value for the **set\_min\_delay** command is the **t<sub>H</sub> Requirement** value. Equation 6 shows the derivation of this conversion.

$$\begin{aligned}
 (6) \quad & \text{arrival} - \text{required} > 0 \\
 & \text{arrival} = \text{dst.in} \\
 & \text{required} = \text{min\_delay} + \text{dst.clk} + \text{dst.uth}
 \end{aligned}$$

$$\text{dst.in} - (\text{min\_delay} + \text{dst.clk} + \text{dst.uth})$$

$$\begin{aligned}
 & t_H \text{ requirement} - \text{actual } t_H > 0 \\
 & \text{actual } t_H = \text{dst.clk} + \text{dst.uth} - \text{dst.in} \\
 & t_H \text{ requirement} - (\text{dst.clk} + \text{dst.uth} - \text{dst.in}) > 0
 \end{aligned}$$

$$\text{set\_min\_delay} = -t_H \text{ requirement}$$

Table 7-7 shows the different ways you can make  $t_H$  assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the `set_min_delay` command.

$t_H$ Requirement Options	<code>set_min_delay</code> Options
-to <pin>	-from [get_ports <pin>] -to [get_registers *]
-to <clock>	-from [get_ports *] -to [get_clocks <clock>]
-to <register>	-from [get_ports *] -to [get_registers <register>]
-from <pin> -to <register>	-from [get_ports <pin>] -to [get_registers <register>]
-from <clock> -to <pin>	-from [get_ports <pin>] -to [get_clocks <clock>] (1)

**Notes to Table 7-7:**

- (1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, `-to <pin>`. If the pin feeds registers clocked by different clocks, use `set_input_delay` to constrain the paths properly. Refer to "Input and Output Delay" on page 7-39 for additional information.

To convert a global  $t_H$  assignment to an equivalent SDC exception, use the command shown in Example 7-11.

**Example 7-11. Converting a Global  $t_H$  Assignment to an Equivalent SDC Exception**

```
set_min_delay -from [all_inputs] -to [all_registers] <negative  $t_H$  value>
```

## $t_{CO}$ Requirement

The  $t_{CO}$  Requirement assignment specifies the maximum acceptable clock to output delay to the output pin. The QSF variable for the  $t_{CO}$  Requirement assignment is TCO\_REQUIREMENT. You can convert the  $t_{CO}$  Requirement assignment to the `set_max_delay` command or the `set_output_delay` with the `-max` option. The delay value for the `set_output_delay` command is `<latch - launch +  $t_{CO}$  requirement>`. Refer to the labeled paths in Figure 7-27 to understand the names in Equations 7 and 8.

**Figure 7-27. Path Names**

Equation 7 shows the derivation of this conversion.

- (7)  $\text{required} - \text{arrival} > 0$   
 $\text{required} = \text{latch} - \text{output\_delay}$   
 $\text{arrival} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}$   
 $\text{output\_delay} = \text{srctodst} + \text{dst.in} + \text{dst.utsu} - \text{dst.clk} - \text{board.dstclk} + \text{board.srcclk}$

$$(\text{latch} - \text{output\_delay}) - (\text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$

$$t_{\text{co}} \text{ requirement} - \text{actual } t_{\text{co}} > 0$$

$$\text{actual } t_{\text{co}} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}$$

$$t_{\text{co}} \text{ requirement} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0$$

$$t_{\text{co}} \text{ requirement} = \text{latch} - \text{launch} - \text{output\_delay}$$

$$\text{output\_delay} = \text{latch} - \text{launch} - t_{\text{co}} \text{ requirement}$$

The delay value is the difference between the period of the clock source of the register and the  $t_{\text{CO}}$  Requirement value, as illustrated in Figure 7-28.

**Figure 7-28.  $t_{\text{CO}}$  Requirement**

The delay value for the `set_max_delay` command is the  $t_{CO}$  Requirement value. Equation 8 shows the derivation of this conversion.

$$\begin{aligned}
 (8) \quad & \text{required} - \text{arrival} > 0 \\
 & \text{required} = \text{set\_max\_delay} \\
 & \text{arrival} = \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & \text{set\_max\_delay} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0 \\
 \\
 & t_{co} \text{ requirement} - \text{actual } t_{co} > 0 \\
 & \text{actual } t_{co} = \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & t_{co} \text{ requirement} - (\text{src.clk} + \text{src.utco} + \text{src.out}) > 0 \\
 \\
 & \text{set\_max\_delay} = t_{co} \text{ requirement}
 \end{aligned}$$

Table 7-8 shows the different ways you can make  $t_{CO}$  assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the `set_max_delay` exception.

$t_{CO}$ Requirement Options	<code>set_max_delay</code> Options
-to <pin>	-from [get_registers *] -to [get_ports <pin>]
-to <clock>	-from [get_clocks <clock>] -to [get_ports *]
-to <register>	-from [get_registers <register>] -to [get_ports *]
-from <register> -to <pin>	-from [get_registers <register>] -to [get_ports <pin>]
-from <clock> -to <pin>	-from [get_clocks <clock>] -to [get_ports <pin>] (1)

**Notes to Table 7-8:**

- (1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, -to <pin>. If the pin feeds registers clocked by different clocks, you should use `set_output_delay` to constrain the paths properly.

To convert a global  $t_{CO}$  assignment to an equivalent SDC exception, use the command in Example 7-12.

**Example 7-12. Converting a Global  $t_{CO}$  Assignment to an Equivalent SDC Exception**

```
set_max_delay -from [all registers] -to [all_outputs] <tCO value>
```

## Minimum $t_{CO}$ Requirement

The **Minimum  $t_{CO}$  Requirement** assignment specifies the minimum acceptable clock to output delay to the output pin. The QSF variable for the **Minimum  $t_{CO}$  Requirement** assignment is `MIN_TCO_REQUIREMENT`. You can convert the **Minimum  $t_{CO}$  Requirement** assignment to the `set_min_delay` command or the `set_output_delay` command with the `-min` option. The delay value for the `set_output_delay` command is `<latch - launch + minimum  $t_{CO}$  requirement>`. Refer to the labeled paths in [Figure 7-29](#) to understand the names in [Equations 9](#) and [10](#).

**Figure 7-29. Path Names**

[Equation 9](#) shows the derivation of this conversion.

$$\begin{aligned}
 (9) \quad & \text{arrival} + \text{required} > 0 \\
 & \text{arrival} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & \text{required} = \text{latch} - \text{output\_delay} \\
 & \text{output\_delay} = \text{srctodst} + \text{dst.in} - \text{dst.uth} - \text{dst.clk} - \text{board.dstclk} + \text{board.srcclk} \\
 & (\text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}) - (\text{latch} - \text{output\_delay}) > 0 \\
 & \text{minimum } t_{CO} - \text{minimum } t_{CO} \text{ requirement} > 0 \\
 & \text{minimum } t_{CO} = \text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & (\text{launch} + \text{src.clk} + \text{src.utco} + \text{src.out}) - \text{minimum } t_{CO} \text{ requirement} > 0 \\
 & \text{minimum } t_{CO} \text{ requirement} = \text{latch} - \text{launch} - \text{output\_delay} \\
 & \text{output\_delay} = \text{latch} - \text{launch} - \text{minimum } t_{CO} \text{ requirement}
 \end{aligned}$$

The delay value for the `set_min_delay` command is the **Minimum  $t_{CO}$  Requirement**. Equation 10 shows the derivation of this conversion.

$$\begin{aligned}
 (10) \quad & \text{arrival} - \text{required} > 0 \\
 & \text{arrival} = \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & \text{required} = \text{min\_delay} \\
 & (\text{src.clk} + \text{src.utco} + \text{src.out}) - (\text{set\_min\_delay}) > 0 \\
 \\
 & \text{minimum } t_{CO} - \text{minimum } t_{CO} \text{ requirement} > 0 \\
 & \text{minimum } t_{CO} = \text{src.clk} + \text{src.utco} + \text{src.out} \\
 & (\text{src.clk} + \text{src.utco} + \text{src.out}) - \text{minimum } t_{CO} \text{ requirement} > 0 \\
 \\
 & \text{set\_min\_delay} = \text{minimum } t_{CO} \text{ requirement}
 \end{aligned}$$

Table 7-9 shows the different ways you can make minimum  $t_{CO}$  assignments in the Quartus II Classic Timing Analyzer, and the corresponding options for the `set_min_delay` exception.

Minimum $t_{CO}$ Requirement Options	<code>set_min_delay</code> Options
-to <pin>	-from [get_registers *] -to [get_ports <pin>]
-to <clock>	-from [get_clocks <clock>] -to [get_ports *]
-to <register>	-from [get_registers <register>] -to [get_ports *]
-from <register> -to <pin>	-from [get_registers <register>] -to [get_ports <pin>]
-from <clock> -to <pin>	-from [get_clocks <clock>] -to [get_ports <pin>] (1)

**Notes to Table 7-9:**

- (1) If the pin in this assignment feeds registers clocked by the same clock, it is equivalent to the first option, -to <pin>. If the pin feeds registers clocked by different clocks, you should use `set_output_delay` to constrain the paths properly.

To convert a global **Minimum  $t_{CO}$  Requirement** to an equivalent SDC exception, use the command shown in Example 7-13.

**Example 7-13. Converting a Global minimum  $t_{CO}$  Requirement to an Equivalent SDC Exception**

```
set_min_delay -from [all_registers] -to [all_outputs] <minimum tCO value>
```

## $t_{PD}$ Requirement

The  $t_{PD}$  Requirement assignment specifies the maximum acceptable input to non-registered output delay, that is, the time required for a signal from an input pin to propagate through combinational logic and appear at an output pin. The QSF variable for the  $t_{PD}$  Requirement assignment is TPD\_REQUIREMENT. You can use the `set_max_delay` command in the Quartus II TimeQuest Timing Analyzer as an equivalent constraint as long as you account for input and output delays. The  $t_{PD}$  Requirement assignment does not take into account input and output delays, but the `set_max_delay` exception does, so you must modify the `set_max_delay` value to take into account input and output delays.

### Combinational Path Delay Scenario

Figure 7-30 shows a simple circuit followed by an example of a  $t_{PD}$  Requirement to `set_max_delay` conversion.

Figure 7-30.  $t_{PD}$  Example

Assume the circuit has the following assignments in the Quartus II Classic Timing Analyzer:

- Clock period of 10 ns
- $t_{PD}$  Requirement from a\_in to comb\_out of 10 ns
- Input Max Delay on a\_in relative to clk of 2 ns
- Output Max Delay on comb\_out relative to clk of 2 ns

The path from a\_in to comb\_out is not affected by the input and output delays. The slack is equal to the  $\langle t_{PD} \text{ Requirement from a\_in to comb\_out} \rangle - \langle \text{path delay from a\_in to comb\_out} \rangle$ .

Assume the circuit has the SDC constraints shown in Example 7-14 in the Quartus II TimeQuest Timing Analyzer:

**Example 7–14. SDC Constraints**

---

```
create_clock -period 10 -name clk [get_ports clk]
set_max_delay -from a_in -to comb_out 10
set_input_delay -clk clk 2 [get_ports a_in]
set_output_delay -clk clk 2 [get_ports comb_out]
```

---

The path from a\_in to comb\_out is affected by the input and output delays. The slack is equal to:

$\langle \text{set\_max\_delay value from a\_in to comb\_out} \rangle - \langle \text{input delay} \rangle - \langle \text{output delay} \rangle - \langle \text{path delay from a\_in to comb\_out} \rangle$

To convert a global **t<sub>PD</sub> Requirement** assignment to an equivalent SDC exception, use the command shown in [Example 7–15](#). You should add the input and output delays to the value of your converted **t<sub>PD</sub> Requirement** (**set\_max\_delay** exception value) to achieve an equivalent SDC exception.

**Example 7–15. Converting a Global t<sub>PD</sub> Requirement Assignment to an Equivalent SDC Exception**

---

```
set_max_delay -from [all_inputs] -to [all_outputs] <value>
```

---

**Minimum t<sub>PD</sub> Requirement**

The **Minimum t<sub>PD</sub> Requirement** assignment specifies the minimum acceptable input to non-registered output delay, that is, the minimum time required for a signal from an input pin to propagate through combinational logic and appear at an output pin. The QSF variable for the **Minimum t<sub>PD</sub> Requirement** assignment is MIN\_TPD\_REQUIREMENT. You can use the **set\_min\_delay** command in the Quartus II TimeQuest Timing Analyzer as an equivalent constraint as long as you account for input and output delays. The **Minimum t<sub>PD</sub> Requirement** assignment does not take into account input and output delays, but the **set\_min\_delay** exception does.

Refer to “[Combinational Path Delay Scenario](#)” on page 7–50 to see how input and output delays affect minimum and maximum delay exceptions.

To convert a global **Minimum t<sub>PD</sub> Requirement** assignment to an equivalent SDC exception, use the following command:

**Example 7–16. Converting a Global Minimum t<sub>PD</sub> Requirement Assignment to an Equivalent SDC Exception**

---

```
set_min_delay -from [all_inputs] -to [all_outputs] <value>
```

---

## Cut Timing Path

The **Cut Timing Path** assignment in the Quartus II Classic Timing Analyzer is equivalent to the **set\_false\_path** command in the Quartus II TimeQuest Timing Analyzer. The QSF variable for the **Cut Timing Path** assignment is CUT.

## Maximum Delay

The **Maximum Delay** assignment specifies the maximum required delay for the following types of paths:

- Pins to registers
- Registers to registers
- Registers to pins

The QSF variable for the **Maximum Delay** assignment is MAX\_DELAY. This requirement overwrites the requirement computed from the clock setup relationship and clock skew. There is no equivalent constraint in the Quartus II TimeQuest Timing Analyzer.

The **Maximum Delay** assignment for the Quartus II Classic Timing Analyzer is not related to the **set\_max\_delay** exception in the Quartus II TimeQuest Timing Analyzer.

## Minimum Delay

The **Minimum Delay** assignment specifies the minimum required delay for the following types of paths:

- Pins to registers
- Registers to registers
- Registers to pins

The QSF variable for the **Minimum Delay** assignment is MIN\_DELAY. This requirement overwrites the requirement computed from the clock hold relationship and clock skew. There is no equivalent constraint in the Quartus II TimeQuest Timing Analyzer.

The **Minimum Delay** assignment for the Quartus II Classic Timing Analyzer is not related to the **set\_min\_delay** exception in the Quartus II TimeQuest Timing Analyzer.

## Maximum Clock Arrival Skew

The **Maximum Clock Arrival Skew** assignment specifies the maximum clock skew between a set of registers. The QSF variable for the **Maximum Clock Arrival Skew** assignment is `MAX_CLOCK_ARRIVAL_SKEW`. In the Quartus II Classic Timing Analyzer, this assignment is specified between a clock node name and a set of registers. **Maximum Clock Arrival Skew** is not supported in the Quartus II TimeQuest Timing Analyzer.

## Maximum Data Arrival Skew

The **Maximum Data Arrival Skew** assignment specifies the maximum data arrival skew between a set of registers, pins, or both. The QSF variable for the **Maximum Data Arrival Skew** assignment is `MAX_DATA_ARRIVAL_SKEW`. In this case, the data arrival delay represents the  $t_{CO}$  from the clock to the given register, pin, or both. This assignment is specified between a clock node and a set of registers, pins, or both.

The Quartus II TimeQuest Timing Analyzer does not support a constraint to specify maximum data arrival skew, but you can specify setup and hold times relative to a clock port to constrain an interface like this.

Figure 7–31 shows a simplified source-synchronous interface used in the following example.

**Figure 7–31. Source-Synchronous Interface Diagram**

### Constraining Skew on an Output Bus

This example constrains the interface so that all bits of the `data_out` bus go off-chip between 2 and 3 ns after the `clk_out` signal. Assume that `clock_in` and `clock_out` have a period of 8 ns.

The following equations and example shows how to create timing requirements that satisfy the timing relationships shown in Figure 7–32.

**Figure 7–32. Source-Synchronous Timing Diagram**

Equation 11 shows how to compute the value for the **set\_output\_delay -min** command that creates the 2 ns hold requirement on the destination. For hold requirement calculations in which source and destination clocks are the same,  $\langle latch \rangle - \langle launch \rangle = 0$ .

$$\begin{aligned}
 (11) \quad & \text{latch} - \text{launch} = 0 \text{ ns} \\
 & \text{output delay} = \text{latch} - \text{launch} - 2 \text{ ns} \\
 & \text{output delay} = -2 \text{ ns}
 \end{aligned}$$

Equation 12 shows how to compute the value for the **set\_output\_delay** command that creates the 3 ns setup requirement on the destination. For setup requirement calculations in which source and destination clocks are the same,  $\langle latch \rangle - \langle launch \rangle = \text{clock period}$ .

$$\begin{aligned}
 (12) \quad & \text{latch} - \text{launch} = 8 \text{ ns} \\
 & \text{output delay} = \text{latch} - \text{launch} - 3 \text{ ns} \\
 & \text{output delay} = 5 \text{ ns}
 \end{aligned}$$

Refer to “I/O Constraints” on page 7–38 for an explanation of the above equations.

Example 7-17 shows the three constraints together.

---

**Example 7-17. Constraining a DDR Interface**

```
set period 8.000
create_clock -period $period \
            -name clock_in \
            clock_in
derive_pll_clocks
set_output_delay -add_delay \
  -clock ddr_pll_1_inst|altpll_component|pll|CLK[0] \
  -reference_pin clk_out \
  -min -2.000 \
  [get_ports data_out*]
set_output_delay -add_delay \
  -clock ddr_pll_1_inst|altpll_component|pll|CLK[0] \
  -reference_pin clk_out \
  -max [expr $period - 3.000] \
  [get_ports data_out*]
```

---

## Conversion Utility

The Quartus II TimeQuest Timing Analyzer includes a conversion utility to help you convert Quartus II Classic timing assignments in a QSF file to SDC constraints in an SDC file. The utility can use information from your project report database (in the `\db` folder), if it exists, so you should compile your design before the conversion.

The conversion utility ignores all disabled QSF assignments. Disabled assignments say **No** in the **Enabled?** column of the Assignment Editor, and include the `-disable` option in the QSF file.

Refer to “[Conversion Utility](#)” on page 7-3 to learn how to run the conversion utility.

## Unsupported Global Assignments

The conversion utility checks whether any of the global timing assignments in [Table 7–10](#) exist in your project. Any global assignments not supported by the conversion utility are ignored during the conversion. Refer to the indicated page for information about each assignment, and how to manually convert these global assignments to SDC commands.

Assignment Name	QSF Variable	More Information
$t_{SU}$ Requirement	TSU_REQUIREMENT	<a href="#">page 7–40</a>
$t_H$ Requirement	TH_REQUIREMENT	<a href="#">page 7–43</a>
$t_{CO}$ Requirement	TCO_REQUIREMENT	<a href="#">page 7–45</a>
Minimum $t_{CO}$ Requirement	MIN_TCO_REQUIREMENT	<a href="#">page 7–48</a>
$t_{PD}$ Requirement	TPD_REQUIREMENT	<a href="#">page 7–50</a>
Minimum $t_{PD}$ Requirement	MIN_TPD_REQUIREMENT	<a href="#">page 7–51</a>

## Recommended Global Assignments

Once any unsupported assignments have been identified, the conversion utility checks the global assignments in [Table 7–11](#) to ensure they match the specified values.

Quartus II Classic Assignment Name	QSF Variable	Value
Cut off clear and preset signal paths	CUT_OFF_CLEAR_AND_PRESET_PATHS	ON
Cut off feedback from I/O pins	CUT_OFF_IO_PIN_FEEDBACK	ON
Cut off read during write signal paths	CUT_OFF_READ_DURING_WRITE_PATHS	ON
Analyze latches as synchronous elements	ANALYZE_LATCHES_AS_SYNCHRONOUS_ELEMENTS	ON
Enable Clock Latency	ENABLE_CLOCK_LATENCY	ON
Display Entity Name	PROJECT_SHOW_ENTITY_NAME	ON

The following assignments are checked to ensure the functionality of the Quartus II Classic Timing Analyzer with the specified values corresponds to the behavior of the Quartus II TimeQuest Timing Analyzer.

- **Cut off clear and preset signal paths**—Quartus II The TimeQuest Timing Analyzer does not support this functionality. You should use Recovery and Removal analysis instead to analyze register control paths. The Quartus II Classic Timing Analyzer does not support this option.
- **Cut off feedback from I/O pins**—The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF.
- **Cut off read during write signal paths**—The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF.
- **Analyze latches as synchronous elements**—The Quartus II TimeQuest Timing Analyzer analyzes latches as synchronous elements by default and does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF. Beginning with version 5.1 of the Quartus II software, the Quartus II Classic Timing Analyzer analyzes latches as synchronous elements by default.
- **Enable Clock Latency**—The Quartus II TimeQuest Timing Analyzer includes clock latency in its calculations. The Quartus II TimeQuest Timing Analyzer does not match the functionality of the Quartus II Classic Timing Analyzer when this assignment is OFF. Latency on a clock can be viewed as a simple delay on the clock path, and affects clock skew. This is in contrast to an offset, which alters the setup and hold relationship between two clocks. Refer to [“Offset and Latency Example” on page 7–15](#) for an example of the different effects of offset and latency. When you turn on **Enable Clock Latency** in the Quartus II Classic Timing Analyzer, it affects the following aspects of timing analysis:
  - **Early Clock Latency** and **Late Clock Latency** assignments are honored
  - The compensation delay of a PLL is analyzed as latency
  - For clock settings where you do not specify an offset, the automatically computed offset is treated as latency.
- **Display Entity Name**—Any entity-specific assignments are ignored in the Quartus II TimeQuest Timing Analyzer because they do not include the entity name when this option is ON.

If your design meets timing requirements in the Quartus II Classic Timing Analyzer without all of the settings recommended in [Table 7–11 on page 7–56](#), you should perform one of the following actions.

- Change the settings and re-constrain and re-verify as necessary.  
*or*
- Add or modify SDC constraints as appropriate because analysis in the Quartus II TimeQuest Timing Analyzer may be different after conversion.

## Clock Conversion

Next, the conversion utility adds the **derive\_pll\_clocks** command to the SDC file. This command creates generated clocks on all PLL outputs in your design each time the SDC file is read. The command does not add a clock on the FPGA port that drives the PLL input.

The conversion utility includes the **derive\_pll\_clocks -use\_tan\_name** command in the SDC file it creates. The **-use\_tan\_name** option overrides the default clock naming behavior (the PLL pin name) so the clock name is the same as the net name in the Quartus II Classic Timing Analyzer.

Including the **-use\_tan\_name** option ensures that the conversion utility converts clock-to-clock exceptions properly. If you remove the **-use\_tan\_name** option, you must also edit references to the clock names in other SDC commands so that they match the PLL pin names.

If your design includes a global  $f_{MAX}$  assignment, the assignment is converted to a **derive\_clocks** command. The behavior of a global  $f_{MAX}$  assignment is different from the behavior of clocks created with the **derive\_clocks** command, and you should use the **report\_clocks** command when you review conversion results to evaluate the clock settings. Refer to [“Automatic Clock Detection” on page 7–19](#) for an explanation of the differences. As soon as you know the appropriate clock settings, you should use **create\_clock** or **create\_generated\_clock** commands instead of the **derive\_clocks** command.

The conversion utility adds a **post\_message** command before the **derive\_clocks** command to remind you that the clocks are derived automatically. The Quartus II TimeQuest Timing Analyzer displays the reminder the first time it reads the SDC file. Remove or comment out the **post\_message** command to prevent the message from displaying.

Next, the conversion utility identifies and converts clock settings in the QSF file. If a project database exists, the utility also identifies and converts any additional clocks in the report file that are not in the QSF, such as PLL base clocks.

If you change the PLL input frequency, you must modify the SDC constraint manually.

The conversion utility ignores clock offsets on generated clocks. Refer to “Clock Offset” on page 7–14 for information about how to use offset values in the Quartus II TimeQuest Timing Analyzer.

## Instance Assignment Conversion

Next, the conversion utility converts the following instance assignments in Table 7–12. Refer to the indicated page for information about each assignment.

Assignment Name	QSF Variable	More Information
Late Clock Latency	LATE_CLOCK_LATENCY	page 7–34
Early Clock Latency	EARLY_CLOCK_LATENCY	
Clock Setup Uncertainty	CLOCK_SETUP_UNCERTAINTY	page 7–34
Clock Hold Uncertainty	CLOCK_HOLD_UNCERTAINTY	
Multicycle (1)	MULTICYCLE	page 7–37
Source Multicycle (2)	SRC_MULTICYCLE	
Multicycle Hold (3)	HOLD_MULTICYCLE	
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	
Clock Enable Multicycle	CLOCK_ENABLE_MULTICYCLE	page 7–38
Clock Enable Source Multicycle	CLOCK_ENABLE_SOURCE_MULTICYCLE	
Clock Enable Multicycle Hold	CLOCK_ENABLE_MULTICYCLE_HOLD	
Clock Enable Source Multicycle Hold	CLOCK_ENABLE_SOURCE_MULTICYCLE_HOLD	
Cut Timing Path	CUT	page 7–52
Input Maximum Delay	INPUT_MAX_DELAY	page 7–39
Input Minimum Delay	INPUT_MIN_DELAY	
Output Maximum Delay	OUTPUT_MAX_DELAY	
Output Minimum Delay	OUTPUT_MIN_DELAY	

### Notes to Table 7–12:

- (1) A multicycle assignment can also be known as a “destination multicycle setup” assignment.
- (2) A source multicycle assignment can also be known as a “source multicycle setup” assignment.
- (3) A multicycle hold can also be known as a “destination multicycle hold” assignment.

Depending on input and output delay assignments, you may receive a warning message when the SDC file is read. The message warns that the `set_input_delay` commands, `set_output_delay` commands, or both are

missing the `-max` option, `-min` option, or both. Refer to [“Input and Output Delay” on page 7-39](#) for an explanation of why the warning occurs and how to avoid it.

Beginning in version 7.1 of the Quartus II software, the conversion utility automatically adds multicycle hold exceptions for each multicycle setup assignment. The value of each multicycle hold exception depends on the **Default hold multicycle** assignment value in your project. If the value is **One**, the conversion utility uses a value of 0 (zero) for each multicycle hold exception it adds. If the value is **Same as multicycle**, the conversion utility uses a value one less than the corresponding multicycle setup assignment value for each multicycle hold exception it adds. Refer to [“Hold Multicycle” on page 7-24](#) for more information on hold multicycle differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers.

Next, the conversion utility converts the following instance assignments in [Table 7-13](#). Refer to the indicated page for information about each assignment. If the  $t_{PD}$  and minimum  $t_{PD}$  assignment targets also have input or output delays that apply to them, the  $t_{PD}$  and minimum  $t_{PD}$  conversion values may be incorrect. This is described in more detail on the indicated pages for the appropriate assignments.

<i>Table 7-13. Instance Timing Assignments</i>		
Assignment Name	QSF Variable	More Information
$t_{PD}$ Requirement (1)	TPD_REQUIREMENT	<a href="#">page 7-50</a>
Minimum $t_{PD}$ Requirement (1)	MIN_TPD_REQUIREMENT	<a href="#">page 7-51</a>
Setup Relationship	SETUP_RELATIONSHIP	<a href="#">page 7-33</a>
Hold Relationship	HOLD_RELATIONSHIP	<a href="#">page 7-34</a>

**Note to Table 7-13:**

- (1) Refer to [“ \$t\_{PD}\$  and Minimum  \$t\_{PD}\$  Requirement Conversion” on page 7-71](#) for more information about how the conversion utility converts single-point  $t_{PD}$  and minimum  $t_{PD}$  assignments.

The conversion utility converts Quartus II Classic I/O timing assignments to FPGA-centric SDC constraints. Table 7-14 includes Quartus II Classic assignments, the equivalent FPGA-centric SDC constraints, and recommended system-centric SDC constraints.

**Table 7-14. Quartus II Classic and Quartus II TimeQuest Equivalent Constraints**

Quartus II Classic	FPGA-Centric SDC	System-Centric SDC	More Information
t <sub>SU</sub> Requirement (1)	set_max_delay	set_input_delay -max	page 7-40
t <sub>H</sub> Requirement (1)	set_min_delay	set_input_delay -min	page 7-43
t <sub>CO</sub> Requirement (2)	set_max_delay	set_output_delay -max	page 7-45
Minimum t <sub>CO</sub> Requirement (2)	set_min_delay	set_output_delay -min	page 7-48

**Notes to Table 7-14:**

- (1) Refer to “t<sub>PD</sub> and Minimum t<sub>PD</sub> Requirement Conversion” on page 7-71 for more information about how the conversion utility converts this type of assignment.
- (2) Refer to “t<sub>CO</sub> Requirement Conversion” on page 7-62 for more information about how the conversion utility converts this type of assignment.

The conversion utility can convert Quartus II Classic I/O timing assignments only to the FPGA-centric constraints without additional information about your design. Making system-centric constraints requires information about the external circuitry interfacing with the FPGA such as external clocks, clock latency, board delay, and clocking exceptions. You cannot convert Quartus II Classic timing assignments to system-centric constraints without that information. If you use the conversion utility, you can modify the SDC constraints to change the FPGA-centric constraints to system-centric constraints as appropriate.

### PLL Phase Shift Conversion

The conversion utility does not account for PLL phase shifts when it converts values of the following FPGA-centric I/O timing assignments:

- t<sub>SU</sub> Requirement
- t<sub>H</sub> Requirement
- t<sub>CO</sub> Requirement
- Minimum t<sub>CO</sub> Requirement

If any of your paths go through PLLs with a phase shift, you must correct the converted values for those paths according to the following formula:

$$(13) \quad \langle \text{correct value} \rangle = \langle \text{converted value} \rangle - \frac{(\langle \text{pll output period} \rangle \times \langle \text{phase shift} \rangle)}{360}$$

[Example 7-18](#) shows the incorrect conversion result for a  $t_{CO}$  assignment and how to correct it. For the example, assume the PLL output frequency is 200 MHz (period is 5 ns), the phase shift is 90 degrees, the  $t_{CO}$  **Requirement** value is 1 ns, and it is made to `data[0]`. The QSF file contains the following assignment:

---

**Example 7-18. Assignment**

```
set_instance_assignment -name TCO_REQUIREMENT -to data[0] 1.0
```

---

The conversion utility generates the SDC command shown in [Example 7-19](#).

---

**Example 7-19. SDC Command**

```
set_max_delay -from [get_registers *] -to [get_ports data[0]] 1.0
```

---

To correct the value, use the formula and values above, as shown in the following example:

$$1.0 - \frac{(5 \times 90)}{360} = -0.25$$

Then, change the value so the SDC command looks like [Example 7-20](#).

---

**Example 7-20. SDC Command with Correct Values**

```
set_max_delay -from [get_registers *] -to [get_ports data[0]] -0.25
```

---

### *$t_{CO}$ Requirement Conversion*

The conversion utility uses a special process to convert  $t_{CO}$  **Requirement** and **Minimum  $t_{CO}$  Requirement** assignments. In addition to the `set_max_delay` or `set_min_delay` commands, the conversion utility adds a `set_output_delay` constraint relative to a virtual clock named N/C (Not a Clock). It also creates the virtual clock named N/C with a period of 10 ns. Adding the virtual clock allows you to report timing on the output paths. Without the virtual clock N/C, the clock used for reporting would be blank. [Example 7-21](#) shows how the conversion utility converts a  $t_{CO}$  **Requirement** assignment of 5.0 ns to `data[0]`.

---

**Example 7-21. Converting a  $t_{CO}$  Requirement Assignment of 5.0 ns to `data[0]`**

```
set_max_delay -from [get_registers *] -to [get_ports data[0]]  
set_output_delay -clock "N/C" 0 [get_ports data[0]]
```

---

## Entity-Specific Assignments

Next, the conversion utility converts the entity-specific assignments listed in [Table 7–15](#) that exist in the **Timing Analyzer Settings** report panel. This usually occurs if you have any timing assignments in your Verilog HDL or VHDL source, which can include MegaCore function files. These entity-specific assignments cannot be automatically converted unless your project is compiled and a `\db` directory exists.

Quartus II Classic	QSF Variable	More Information
Multicycle	MULTICYCLE	page 7–37
Source Multicycle	SRC_MULTICYCLE	
Multicycle Hold	HOLD_MULTICYCLE	
Source Multicycle Hold	SRC_HOLD_MULTICYCLE	
Setup Relationship	SETUP_RELATIONSHIP	page 7–33
Hold Relationship	HOLD_RELATIONSHIP	page 7–34
Cut Timing Path	CUT	page 7–52

You must manually convert all other entity-specific timing assignments.

## Paths between Unrelated Clock Domains

Beginning in version 7.1 of the Quartus II software, the conversion utility can create exceptions that cut paths between unrelated clock domains, which matches the default behavior of the Quartus II Classic Timing Analyzer. When **Cut paths between unrelated clock domains** is on, the conversion utility creates clock groups with the `set_clock_groups` command and uses the `-exclusive` option to cut paths between the clock groups.

## Unsupported Instance Assignments

Finally, the conversion utility checks for the following unsupported instance assignments listed in [Table 7–16](#) and warns you if any exist. Refer to the indicated page for information about each assignment.

You can manually convert some of the assignments to SDC constraints.

Assignment Name	QSF Variable	More Information
Inverted Clock	INVERTED_CLOCK	<a href="#">page 7–35</a>
Maximum Clock Arrival Skew	MAX_CLOCK_ARRIVAL_SKEW	<a href="#">page 7–53</a>
Maximum Data Arrival Skew	MAX_DATA_ARRIVAL_SKEW	<a href="#">page 7–53</a>
Maximum Delay	MAX_DELAY	<a href="#">page 7–52</a>
Minimum Delay	MIN_DELAY	<a href="#">page 7–52</a>
Virtual Clock Reference	VIRTUAL_CLOCK_REFERENCE	<a href="#">page 7–36</a>

## Reviewing Conversion Results

You must review the messages that are generated during the conversion process, and review the SDC file for correctness and completeness. Warning and critical warning messages identify significant differences between the Quartus II Classic Timing Analyzer and Quartus II TimeQuest Timing Analyzer behaviors. In some cases, warning messages indicate that the conversion utility ignored assignments because it could not determine the intended functionality of your design. You must add to or modify the SDC constraints as necessary based on your knowledge of the design.

The conversion utility creates an SDC file with the same name as your current revision, *<revision>.sdc*, and it overwrites any existing *<revision>.sdc* file. If you use the conversion utility to create an SDC file, you should make additions or corrections in a separate SDC file, or a copy of the SDC file created by the conversion utility. That way, you can re-run the conversion utility later without overwriting your additions and changes. If you have constraints in multiple SDC files, refer to [“Constraint File Priority”](#) on [page 7–10](#) to learn how to add constraints to your project.

### Warning Messages

The conversion utility may generate any of the following warning messages. Refer to the information provided for each warning message to learn what to do in that instance.

**Ignored QSF Variable <assignment>**

The conversion utility ignored the specified assignment. Determine whether an equivalent constraint is necessary and manually add one if appropriate. Refer to [“Timing Assignment Conversion” on page 7–33](#) for information about conversions for all QSF timing assignments.

**Global <name> = <value>**

The conversion utility ignored the global assignment <name>. Manually add an equivalent constraint if appropriate. Refer to [“Unsupported Global Assignments” on page 7–56](#) for information about conversions for these assignments.

**QSF: Expected <name> to be set to <expected value> but it is set to <actual value>**

The behavior of the Quartus II TimeQuest Timing Analyzer is closest to the Quartus II Classic Timing Analyzer when the value for the specified assignment is the expected value. Because the actual assignment value is not the expected value in your project, the Quartus II TimeQuest Timing Analyzer analysis may be different from the Quartus II Classic Timing Analyzer analysis. Refer to [“Recommended Global Assignments” on page 7–56](#) for an explanation about the indicated QSF variable names.

**QSF: Found Global Fmax Requirement. Translation will be done using derive\_clocks**

Your design includes a global  $f_{MAX}$  requirement, and the requirement is converted to the `derive_clocks` command. Refer to [“Default Required  \$f\_{MAX}\$  Assignment” on page 7–35](#) for information about how to convert to an SDC constraint.

**TAN Report Database not found. HDL based assignments will not be migrated**

You did not analyze your design with the Quartus II Classic Timing Analyzer before running the conversion utility. As a result, the conversion utility did not convert any timing assignments in your HDL source code to SDC constraints. If you have timing assignments in your HDL source code, you must find and convert them manually, or analyze your design with the Quartus II Classic Timing Analyzer and rerun the conversion utility.

**Ignored Entity Assignment (Entity <entity>): <variable> = <value> -from <from> -to <to>**

The conversion utility ignored the specified entity assignment because the utility cannot automatically convert the assignment. [Table 7–15 on page 7–63](#) lists the entity-specific assignments the script can convert automatically.

Refer to “[Timing Assignment Conversion](#)” on page 7-33 for information about how to convert the entity assignment manually.

#### **Ignoring OFFSET\_FROM\_BASE\_CLOCK assignment for clock <clock>**

In some cases, this assignment is used to work around a limitation in how the Quartus II Classic Timing Analyzer handles some forms of clock inversion. The conversion script ignores the assignment because it cannot determine whether the assignment is used as a workaround. Review your clock setting and add the assignment in your SDC file if appropriate. Refer to “[Clock Offset](#)” on page 7-14 for more information about converting clock offset.

#### **Clock <clock> has no FMAX\_REQUIREMENT - No clock was generated**

The conversion utility did not convert the clock named <clock> because it has no  $f_{MAX}$  requirement. You should add a clock constraint with an appropriate period to your SDC file.

#### **No Clock Settings defined in QSF file**

If your QSF file has no clock settings, ignore this message. You must add clock constraints in your SDC file manually.

### *Clocks*

Ensure that the conversion utility converted all clock assignments correctly. Run **report\_clocks**, or double-click **Report Clocks** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. Make sure that the right number of clocks is reported. If any clock constraints are missing, you must add them manually with the appropriate SDC commands (**create\_clock** or **create\_generated\_clock**). Confirm that each option for each clock is correct.

The Quartus II TimeQuest Timing Analyzer can create more clocks, such as:

- **derive\_clocks** selecting ripple clocks
- **derive\_pll\_clocks**, adding
  - Extra clocks for PLL switchover
  - Extra clocks for LVDS pulse-generated clocks (~load\_reg)

### *Clock Transfers*

After you confirm that all clock assignments are correct, run **report\_clock\_transfers**, or double-click **Report Clock Transfers** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. The

command generates a summary table with the number of paths between each clock domain. If the number of cross-clock domain paths seems high, remember that all clock domains are related in the Quartus II TimeQuest Timing Analyzer. You must cut unrelated clock domains. Refer to “[Related and Unrelated Clocks](#)” on page 7–13 for information about how to cut unrelated clock domains.

### *Path Details*

If you have unexpected differences between the Quartus II Classic and Quartus II TimeQuest Timing Analyzers on some paths, follow these steps to identify the cause of the difference.

1. List the path in the Quartus II Classic Timing Analyzer.
2. Report timing on the path in the Quartus II TimeQuest Timing Analyzer.
3. Compare slack values.
4. Compare source and destination clocks.
5. Compare the launch/latch times in the Quartus II TimeQuest Timing Analyzer to the setup/hold relationship in the Quartus II Classic Timing Analyzer. The times are absolute in the Quartus II TimeQuest Timing Analyzer and relative in the Quartus II Classic Timing Analyzer.
6. Compare clock latency values.

### *Unconstrained Paths*

Next, run `report_ucp`, or double-click **Report Unconstrained Paths** in the Tasks pane in the Quartus II TimeQuest Timing Analyzer GUI. This command generates a series of reports that detail any unconstrained paths in your design. If your design was completely constrained in the Quartus II Classic Timing Analyzer but there are unconstrained paths in the Quartus II TimeQuest Timing Analyzer, some assignments may not have been converted properly. Also, some of the assignments could be ambiguous. The Quartus II TimeQuest Timing Analyzer analyzes more paths than the Quartus II Classic Timing Analyzer does, so any unconstrained paths might be paths you could not constrain in the Quartus II Classic Timing Analyzer.

### *Bus Names*

If your design includes Quartus II Classic Timing Analyzer timing assignments to buses, and the bus names do not include square brackets enclosing an asterisk, such as: `address[*]`, you should review the SDC constraints to ensure the conversion is correct. Refer to “[Bus Name Format](#)” on page 7–10 for more information.

### *Other*

Review the notes listed in “[Conversion Utility](#)” on page 7–71.

## **Re-Running the Conversion Utility**

You can force the conversion utility to run even if it can find an SDC file according to the priority described in “[Constraint File Priority](#)” on page 7–10. Any method described in “[Conversion Utility](#)” on page 7–3 forces the conversion utility to run even if it can find an SDC file.

## **Notes**

This section describes notes for the Quartus II TimeQuest Timing Analyzer.

### **Output Pin Load Assignments**

The Quartus II TimeQuest Timing Analyzer takes **Output Pin Load** values into account when it analyzes your design. If you change **Output Pin Load** assignments and do not recompile before you analyze timing, you must use the `-force_dat` option when you create the timing netlist. Type the following command at the Tcl console of the Quartus II TimeQuest Timing Analyzer:

```
create_timing_netlist -force_dat ←
```

If you change **Output Pin Load** assignments and recompile before you analyze timing, do not use the `-force_dat` option when you create the timing netlist. You can create the timing netlist with the `create_timing_netlist` command, or with the **Create Timing Netlist** task in the Tasks pane.

Also note that the SDC `set_output_load` command is not supported, so you must make all output load assignments in the Quartus II Settings File (`.qsf`).

## Constraint Target Types

In version 6.0 of the Quartus II software, the Quartus II TimeQuest Timing Analyzer did not support constraints between clocks and non-clocks. Beginning with version 6.1, the Quartus II TimeQuest Timing Analyzer supports mixed exception types; you can apply an exception of any clock/node combination.

## DDR Constraints with the DDR Timing Wizard

The DDR Timing Wizard (DTW) creates an SDC file that contains constraints for a DDR interface. You can use that SDC file with the Quartus II TimeQuest Timing Analyzer to analyze only the DDR interface part of a design.

You should use the SDC file created by DTW for constraining a DDR interface in the Quartus II TimeQuest Timing Analyzer. Additionally, your QSF should not contain timing assignments for the DDR interface if you plan to use the conversion utility to create an SDC file. You should run the conversion utility before you use DTW, and you should choose not to apply assignments to the QSF.

However, if you used DTW and chose to apply assignments to a QSF, before you used the conversion utility, you should remove the DTW-generated QSF timing assignments and re-run the conversion utility. The conversion utility creates some incompatible SDC constraints from the DTW QSF assignments.

## HardCopy Stratix Device Handoff

If you target the HardCopy device family, you should not use the Quartus II TimeQuest Timing Analyzer. The Quartus II TimeQuest Timing Analyzer is not supported for the HardCopy Stratix design process. The Quartus II TimeQuest Timing Analyzer supports HardCopy II series devices.

## Unsupported SDC Features

Some SDC commands and features are not supported by the current version of the Quartus II TimeQuest Timing Analyzer. The following commands are included:

- The `get_designs` command, because the Quartus II software supports a single design, so this command is not necessary
- True latch analysis with time-borrowing feature; it can, however, convert latches to negative-edge-triggered registers
- The case analysis feature

- Loads, clock transitions, input transitions, and other features

## Constraint Passing

The Quartus II software can read constraints generated by other EDA software, and write constraints to be read by other EDA software.

Other synthesis software can generate constraints that target the QSF file. If you change timing constraints in synthesis software after creating an SDC file for the Quartus II TimeQuest Timing Analyzer, you must update the SDC constraints. You can use the conversion utility, or update the SDC file manually.

## Optimization

Gate-level re-timing is not supported if you turn on the Quartus II TimeQuest Timing Analyzer as your default timing analyzer.

If you use physical synthesis with the Quartus II TimeQuest Timing Analyzer, the design may have lower performance.

## Clock Network Delay Reporting

In the Quartus II software version 6.0, the Quartus II TimeQuest Timing Analyzer reports delay on the clock network as a single number, rather than node-to-node segments, as the Quartus II Classic Timing Analyzer does. Beginning with version 6.0 SP1, the TimeQuest Timing Analyzer reports delay on the clock network by node-to-node segments.

## PowerPlay Power Analysis

You must perform the following steps to generate an **Early Power Estimator** output file when you use the Quartus II TimeQuest Timing Analyzer and your design targets one of the following device families:

- Cyclone
- Stratix
- HardCopy Stratix

To generate an **Early Power Estimator** output file for designs targeting those families, you must perform the following steps.

1. Turn off the Quartus II TimeQuest Timing Analyzer. Refer to [“Set the Default Timing Analyzer” on page 7-4](#) to learn how to turn off the Quartus II TimeQuest Timing Analyzer.

2. Manually convert your Quartus II TimeQuest Timing Analyzer timing constraints in the SDC file to Quartus II Classic Timing Analyzer timing assignments. You can use the Assignment Editor to enter your Quartus II Classic Timing Analyzer timing assignments in your QSF file.
3. Perform Quartus II Classic timing analysis.
4. Generate an **Early Power Estimator** output file.
5. Turn on the Quartus II TimeQuest Timing Analyzer.

## Project Management

If you use the `project_open` Tcl command in the Quartus II TimeQuest Timing Analyzer to open a project compiled with an earlier version of the Quartus II software, the Quartus II TimeQuest Timing Analyzer overwrites the compilation results (`\db` folder) without warning. Opening a project any other way results in a warning, and you can choose not to open the project.

## Conversion Utility

This section describes the notes for the QSF assignment to SDC constraint conversion utility.

### *t<sub>PD</sub> and Minimum t<sub>PD</sub> Requirement Conversion*

The conversion utility treats the targets of single-point  $t_{PD}$  and minimum  $t_{PD}$  assignments as device outputs. It does not correctly convert targets of single-point  $t_{PD}$  and minimum  $t_{PD}$  assignments that are device inputs.

The following QSF assignment applies to a device input named `d_in`:

```
set_intance_assignment -name TPD_REQUIREMENT -to d_in "3 ns"
```

The conversion utility creates the following SDC command, regardless of whether `d_in` is a device input or device output:

```
set_max_delay "3 ns" -from [get_ports *] -to [get_ports d_in]
```

You must update any incorrect SDC constraints manually.

July 2006 v6.0.1	Updated for the Quartus II software version 6.0.1: <ul style="list-style-type: none"> <li>● Added section on Clock Objects on page 7-24.</li> <li>● Added examples of Netlist Names on page 7-29.</li> <li>● Replaced figure 7-23 and example 7-9 on page 7-36.</li> <li>● Added note 4 to table 7-6 on page 7-43.</li> <li>● Added “Display Entity Name” to table 7-11 on page 7-57.</li> <li>● Added information to Clock Conversion on pages 7-58 and 7-59.</li> <li>● Added note 3 to table 7-12 on page 7-60.</li> <li>● Added information to Clocks section on page 7-67.</li> <li>● Added Path Details and Unconstrained Paths sections on page 7-68.</li> <li>● Added information to Clock Network Delay Reporting on page 7-72.</li> <li>● Added hand paragraph in Conversion Utility section on page 7-73.</li> <li>● Changed “constraint” to “exception” in many places.</li> </ul>	—
May 2006 v6.0.0	Initial release.	—

## Introduction

Static timing analysis is a method for analyzing, debugging, and validating the timing performance of a design. The classic timing analyzer analyzes the delay of every design path and analyzes all timing requirements to ensure correct circuit operation. Static timing analysis, used in conjunction with functional simulation, allows you to verify overall design operation.

For information about switching to the Quartus II TimeQuest Timing Analyzer, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

As part of the compilation flow, the Quartus® II software automatically performs a static timing analysis so that you do not need to launch a separate timing analysis tool. The Quartus II Classic Timing Analyzer checks every path in the design against your timing constraints for timing violations and reports results in the Timing Analysis reports, giving you immediate access to the data.

This chapter assumes you have some Tcl expertise; Tcl commands are used throughout this chapter to describe alternative methods for making timing analysis assignments. Refer to [“Timing Analysis Using the Quartus II GUI” on page 8–43](#) for GUI-equivalent timing constraints.

This chapter details the following aspects of timing analysis:

- [“Timing Analysis Tool Setup” on page 8–2](#)
- [“Static Timing Analysis Overview” on page 8–2](#)

## Timing Analysis Tool Setup

The Quartus II software version 6.0 and above supports two static timing analysis tools namely, the classic timing analyzer and the Quartus II TimeQuest Timing Analyzer. Use the **Timing Analysis** option under the Settings menu to set the Timing Analyzer that is used in the compilation process.

Arria GX is not supported by the Quartus II Classic Timing Analyzer. To perform a static timing analysis for Arria GX, the Quartus II TimeQuest Timing Analyzer must be enabled.

The following steps set the classic timing analyzer as the default timing analysis tool in the Quartus II software.

1. On the Assignments menu, click **Settings**. The Settings dialog box appears.
2. In the Category list, click the  icon next to **Timing Analysis Settings** to expand the folder.
3. Select the **Use Classic Timing Analyzer during compilation** radio button.

Refer to the *Quartus II TimeQuest Timing Analyzer* chapter of the *Quartus II Handbook* for more information about the Quartus II TimeQuest Timing Analyzer.

## Static Timing Analysis Overview

This section provides information about static timing analysis concepts used throughout this chapter and used by the Quartus II Classic Timing Analyzer. A complete understanding of the concepts presented in this section allows you to take advantage of the powerful static timing analysis features available in the Quartus II software.

Various paths exist within any given design which connect design elements together, including the path from an output of a register to the input of another register. Timing paths play a significant role during a static timing analysis. Understanding the types of timing paths is important for timing closure and optimization. Some of the commonly analyzed paths are described in this section and are shown in [Figure 8–1](#).

- **Clock paths**—Clock paths are the paths from device pins or internally generated clocks (nodes designated as a clock via a clock setting) to the clock ports of sequential elements such as registers.
- **Data paths**—Data paths are the paths from the data output port of a sequential element to the data input port of another sequential element.

- **Asynchronous paths**—Asynchronous paths are paths from a node to the asynchronous set or clear port of a sequential element.

**Figure 8–1. Path Types**

Once the path types are identified, the classic timing analyzer computes data and clock arrival times for all valid register-to-register paths. Data arrival time is the delay from the source clock to the destination register. The Quartus II Classic Timing Analyzer calculates this delay by adding the clock path delay to the source register, the micro clock-to-out ( $\mu t_{CO}$ ) of the source register, and the data path delay from the source register to the destination register. Clock arrival time is the delay from the destination clock node to the destination register. Figure 8–2 shows a data arrival path and a clock arrival path.

**Figure 8–2. Data Arrival and Clock Arrival**

In addition to identifying various paths within a design, the Quartus II Classic Timing Analyzer analyzes clock characteristics to compute the worst-case requirement between any two registers in a single register-to-register path. You must use timing constraints to specify the characteristics of all clock signals in the design before this analysis occurs.

The active clock edge that sends data out of a sequential element, acting as a source for the data transfer, is the launch edge. The active clock edge that captures data at the data port of a sequential element, acting as a destination for the data transfer, is the latch edge.

Figure 8–3 shows a single-cycle system that uses consecutive clock edges to transmit and capture data, a register-to-register path, and the corresponding launch and latch edges timing diagram. In this example, the launch edge sends the data out of register `reg1` at 0 ns, and register `reg2` latch edge captures the data at 5 ns.

**Figure 8–3. Launch Edge and Latch Edge**

By analyzing specific paths relative to the launch and latch edges, the Quartus II Classic Timing Analyzer performs clock setup and clock hold checks, validating them against your timing assignments.

## Clock Analysis

A comprehensive static timing analysis includes analysis of register-to-register, I/O, and asynchronous reset paths. Static Timing Analysis tools use data required times, data arrival times, and clock arrival times to verify circuit performance and detect possible timing violations. The Quartus II Classic Timing Analyzer determines the timing relationships that must be met for the design to correctly function, and checks arrival times against required times to verify timing.

### Clock Setup Check

To determine if a design meets performance, the Quartus II Classic Timing Analyzer calculates clock timing, timing requirements, and timing exceptions to perform a clock setup check at each destination register based on the source and destination clocks and timing constraints, or exceptions that are applicable to those paths. A clock setup check ensures that data launched by a source register is latched correctly by the destination register. To perform a clock setup check, the Quartus II Classic Timing Analyzer determines the clock arrival time and data arrival time at the destination register by using the longest path for the

data arrival time and the shortest path for the clock arrival time. The Quartus II Classic Timing Analyzer then checks that the difference is greater than or equal to the micro setup ( $t_{SU}$ ) of the destination register as shown in Equation 1.

$$(1) \quad \text{Clock Arrival Time} - \text{Data Arrival Time} \geq \text{micro } t_{SU}$$

By default, the Quartus II Classic Timing Analyzer assumes the launched and latched edges happen on consecutive active clock edges.

The results of clock setup checks are reported in terms of slack. Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met, and negative slack indicates the margin by which a requirement is not met. The Quartus II Classic Timing Analyzer determines clock setup slack using Equations 2 through 5.

$$(2) \quad \text{Clock Setup Slack} = \text{Data Required Time} - \text{Data Arrival Time}$$

$$(3) \quad \text{Data Required} = \text{Clock Arrival Time} - \text{micro } t_{SU} - \text{Setup Uncertainty}$$

$$(4) \quad \text{Clock Arrival Time} = \text{Latch Edge} + \text{Shortest Clock Path to Destination Register}$$

$$(5) \quad \text{Data Arrival Time} = \text{Launch Edge} + \text{Longest Clock Path to Source Register} + \text{micro } t_{CO} + \text{Longest Data Delay}$$

The Quartus II Classic Timing Analyzer reports clock setup slack using Equations 6 through 9 (which are equivalent to Equations 2 through 5).

$$(6) \quad \text{Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

$$(7) \quad \text{Largest Register-to-Register Requirement} = \text{Setup Relationship between Source and Destination} + \text{Largest Clock Skew} - \text{micro } t_{CO} \text{ of Source Register} - \text{micro } t_{SU} \text{ of Destination Register}$$

$$(8) \quad \text{Setup Relationship between Source \& Destination Register} = \text{Latch Edge} - \text{Launch Edge} - \text{Setup Uncertainty}$$

$$(9) \quad \text{Largest Clock Skew} = \text{Shortest Clock Path to Destination Register} - \text{Longest Clock Path to Source Register}$$

Both sets of equations can be used to determine the slack value of any path.

### *Clock Hold Check*

To prevent hold violations, the Quartus II Classic Timing Analyzer calculates clock timing, timing requirements, and timing exceptions to perform a clock hold check at each destination register. A clock hold check ensures data launched from the source register is not captured by an active clock edge earlier than the setup latch edge, and that the destination register does not capture data launched from the next active launch edge. To perform a clock hold check, the Quartus II Classic Timing Analyzer determines the clock arrival time and data arrival time at the destination register using the shortest path for the data arrival time and the longest path for the clock arrival time. The Quartus II Classic Timing Analyzer checks that the difference is greater than or equal to the micro hold time ( $t_H$ ) of the destination register, as shown in [Equation 10](#).

$$(10) \quad \text{Data Arrival Time} - \text{Clock Arrival Time} \geq t_H$$

The Quartus II Classic Timing Analyzer determines clock hold slack using [Equations 11 through 14](#).

$$(11) \quad \text{Clock Hold Slack} = \text{Data Arrival Time} - \text{Data Required Time}$$

$$(12) \quad \text{Data Required Time} = \text{Clock Arrival Time} + \text{micro } t_H + \text{Hold Uncertainty}$$

$$(13) \quad \text{Clock Arrival Time} = \text{Latch Edge} + \text{Longest Clock Path to Destination Register}$$

$$(14) \quad \text{Data Arrival Time} = \text{Launch Edge} + \text{Shortest Clock Path to Source Register} + \text{micro } t_{CO} + \text{Shortest Data Delay}$$

The Quartus II Classic Timing Analyzer reports clock hold slack using [Equations 15 through 18](#).

$$(15) \quad \text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

$$(16) \quad \text{Smallest Register-to-Register Requirement} = \text{Hold Relationship between Source \& Destination} + \text{Smallest Clock Skew} - \text{micro } t_{CO} \text{ of Source Register} + \text{micro } t_H \text{ of Destination Register}$$

$$(17) \quad \text{Hold Relationship between Source and Destination Register} = \text{Latch} - \text{Launch} + \text{Hold Uncertainty}$$

$$(18) \quad \text{Smallest Clock Skew} = \text{Longest Clock Path from Clock to Destination Register} - \text{Shortest Clock Path from Clock to Source Register}$$

These equations can be used to determine the slack value of any path.

## Multicycle Paths

Multicycle paths are data paths that require more than one clock cycle to latch data at the destination register. For example, a register may be required to capture data on every second or third rising clock edge.

Figure 8-4 shows an example of a multicycle path between a multiplier's input registers and output register where the destination latches data on every other clock edge.

Refer to "Multicycle" on page 8-15 for more information about multicycle exceptions.

**Figure 8-4. Example Diagram of a Multicycle Path**

Figure 8-5 shows the default clock setup analysis launch and latch edges where multicycle assignment is equal to 1.

**Figure 8-5. Default Clock Setup Analysis**

Figure 8–6 shows an analysis similar to Figure 8–5, but with a multicycle of 2.

**Figure 8–6. Multicycle = 2 Clock Setup Analysis**

## Clock Settings

You can use individual and default clock settings to define the clocks in your design. You can base these clock settings on other clock settings already defined in your design.

To ensure the Quartus II Fitter achieves the desired performance requirements and the Quartus II Classic Timing Analyzer performs a thorough static timing analysis, you must specify all timing assignments prior to compiling the design.

### Individual Clock Settings

Individual clock settings allow you to specify clock properties including performance requirements, offsets, duty cycles, and other properties for individual clock signals in your design.

You can define individual clock settings using the `create_base_clock` Tcl command. The following example defines an individual clock setting named `sys_clk` with a requirement of 100 MHz (10 ns), and assigns it to clock node `clk`.

```
create_base_clock -fmax 100MHz -target clk sys_clk
```

### Default Clock Settings

You can assign a project-wide clock requirement to constrain all detected clocks in a design that do not have individual clock settings.

The `set_global_assignment -name FMAX_REQUIREMENT` Tcl command specifies a global default requirement assignment. The following example defines a 100 MHz default clock requirement:

```
set_global_assignment -name FMAX_REQUIREMENT "100.0 MHz"
```

For best placement and routing results, apply individual clock settings to all clocks in your design. All clocks adopting the default  $F_{MAX}$  are by default unrelated.

## Clock Types

This section describes the types of clocks recognized by the Timing Analyzer:

- Base clocks
- Derived clocks
- Undefined clocks
- PLL clocks

### Base Clocks

A base clock is independent of other clocks in a design. For example, a base clock is typically a clock signal driven directly by a device pin. A base clock is defined by individual clock settings, or automatically detected using the default clock setting.

You can use the `create_base_clock` Tcl command to define a base clock setting and assign the clock setting to a clock node. The following Tcl command creates a clock setting called `sys_clk` with a requirement of 5 ns (200 MHz) and applies the clock setting to clock node `main_clk`:

```
create_base_clock -fmax 5ns -target main_clk sys_clk
```

### Derived Clocks

A derived clock is based on a previously defined base clock. For a derived clock, you can specify the phase shift, offset, multiplication and division factors, and duty cycle relative to the base clock.

You can use the `create_relative_clock` Tcl command to define and assign a derived clock setting. The following example creates a derived clock setting named `system_clockx2` that is twice as fast as the base clock `system_clock` applied to clock node `clkx2`.

```
create_relative_clock -base_clock system_clock -duty_cycle 50 \  
-multiply 2 -target clkx2 system_clockx2
```

### Undefined Clocks

The Quartus II Classic Timing Analyzer detects undeclared clocks in your design and displays a warning similar to the following:

```
Warning: Found pins functioning as undefined clocks and/or memory enables
```

```
Info: Assuming node "clk_src" is an undefined clock
Info: Assuming node "clk_dst" is an undefined clock
```

The Quartus II Classic Timing Analyzer reports actual data delay for undefined clocks, but because no clock requirements exist for undefined clocks, the Quartus II Classic Timing Analyzer does not report slack for any register-to-register paths driven by an undefined clock.

## PLL Clocks

Phase-locked loops (PLLs) are used for clock synthesis in Altera® devices. This device feature is configured and connected to your design using the `altpll` megafunction included with the Quartus II software. Using the MegaWizard® Plug-In Manager, you can customize the input clock frequency, multiplication factors, division factors, and other parameters of the `altpll` megafunction.

For more information about using the PLL feature in your design, refer to the *altpll Megafunction User Guide* or the handbook for the targeted device family.

For PLLs, the Quartus II Classic Timing Analyzer automatically creates derived clock settings based on the parameterization of the PLL and automatically creates a base clock setting for the input clock pin. For example, if the input clock frequency to a PLL is 100 MHz and the multiplication and division ratio is 5:2, the clock period of the PLL clock is set to 4.0 ns and is automatically calculated by the Quartus II Classic Timing Analyzer.

For the Stratix® and Cyclone® device families, you can override the PLL input clock frequency by applying a clock setting to the input clock pin of the PLL. For example, if the PLL input clock period is set to 10 ns (100 MHz) with a multiplication and division ratio of 5:2, but a clock setting of 20 ns (50 MHz) is applied to the input clock pin of the PLL, the setup relationship is 8.0 ns (125 MHz) and not 4.0 ns (250 MHz). The Quartus II Classic Timing Analyzer issues a message similar to the following:

```
Warning: ClockLock PLL
"mypll_test:inst|altpll:altpll_component|_clk1" input frequency
requirement of 200.0 MHz overrides default required fmax of 100.0
MHz -- Slack information will be reported
```

You cannot override the PLL output clock frequency with a clock setting in the Quartus II Classic Timing Analyzer.

## Clock Uncertainty

You can use **Clock Setup Uncertainty** and **Clock Hold Uncertainty** assignments to model jitter, skew, or add a guard band associated with clock signals.

When a clock uncertainty assignment exists for a clock signal, the Timing Analyzer performs the most conservative setup and hold checks. For clock setup check, the setup uncertainty is subtracted from the data required time. [Figure 8-7](#) shows an example of clock sources with a clock setup uncertainty applied.

**Figure 8-7. Clock Setup Uncertainty**

You can create clock uncertainty assignments using the Tcl command `set_clock_uncertainty`. The `set_clock_uncertainty` assignment used with the switch `-setup` specifies a clock setup uncertainty assignment. The following example creates a **Clock Setup Uncertainty** assignment with a value of 2 ns applied to clock signal `clk`:

```
set_clock_uncertainty -to clk -setup 2ns
```

For the clock hold check, the hold uncertainty is added to the data required time. [Figure 8-8](#) shows an example of clock setup check with a clock setup uncertainty and clock hold uncertainty applied.

**Figure 8–8. Clock Hold Uncertainty**

You can use the `set_clock_uncertainty` Tcl command with the option `-hold` to specify a **Clock Hold Uncertainty** assignment. The following example creates a **Clock Hold Uncertainty** assignment with a value of 2 ns for clock signal `clk`.

```
set_clock_uncertainty -to clk -hold 2ns
```

You can also apply the clock uncertainty assignments between two clock sources. The following example creates a **Clock Setup Uncertainty** assignment for clock setup checks where `clk1` is the source clock and `clk2` is the destination clock:

```
set_clock_uncertainty -from clk1 -to clk2 -setup 2ns
```

## Clock Latency

You can use clock latency assignments to model delays from the clock source. For example, you can use clock latency to model an external delay from an ideal clock source, such as an oscillator, to the clock pin or port of the device.

The **Early Clock Latency** assignment allows you to specify the shortest or earliest delay of the clock source. Conversely, the **Late Clock Latency** assignment allows you to specify the longest or latest delay of the clock source.

During setup analysis, the Quartus II Classic Timing Analyzer adds the **Late Clock Latency** assignment value to the source clock path delay and adds the **Early Clock Latency** assignment value to the destination clock path delay when determining clock skew for the path. During clock hold analysis, the Quartus II Classic Timing Analyzer adds the **Early Clock Latency** assignment value to the source clock path delay and adds the **Late Clock Latency** assignment value to the destination clock path delay when determining clock skew for the path.

The **Early Clock Latency** and **Late Clock Latency** assignments do not change the latch and launch edges defined by the clock setting and therefore does not change the setup or hold relationships between source and destination clocks. The clock latency assignments add only delay to the clock network and therefore only affects clock skew.

Figure 8–9 shows the clock edges used to calculate clock skew for a setup check when the **Early Clock Latency** and **Late Clock Latency** assignments are used.

**Figure 8–9. Clock Setup Check Clock Skew**

Figure 8–10 shows the clock edges used to calculate clock skew for a hold check when the **Early Clock Latency** and **Late Clock Latency** assignments are used.

**Figure 8–10. Clock Hold Check Clock Skew**

The Quartus II Classic Timing Analyzer ignores clock latency if the clock signal at the source and destination registers are the same.

You can use the `set_clock_latency` Tcl command with the switches `-early` or `-late` to specify an **Early Clock Latency** assignment or **Late Clock Latency** assignment, respectively. [Example 8-1](#) specifies that the clock signal at `clk2` arrives as early as 1.8 ns and as late as 2.0 ns.

---

**Example 8-1. Specifying Early or Late Clock Latency at `clk2`**

```
set_clock_latency -early -to clk2 1.8ns
set_clock_latency -late -to clk2 2ns
```

---

The early clock latency default value is the same as the late clock latency delay, and the late clock latency default value is the same as the early clock latency delay, if only one is specified.

The **Enable Clock Latency** option must be set to **ON** for the Quartus II Classic Timing Analyzer to analyze clock latency. When this option is set to **ON**, the Quartus II Classic Timing Analyzer reports clock latency as part of the clock skew calculation for either the source or destination clock path depending upon the analysis performed. To set the **Enable Clock Latency** option to **ON**, you can use the following Tcl command:

```
set_global_assignment -name ENABLE_CLOCK_LATENCY ON
```

When the **Enable Clock Latency** option is enabled, the Quartus II Classic Timing Analyzer automatically calculates latencies for derived clocks instead of automatically calculating offsets; for example, PLL compensation delays. These clock path delays are accounted for as clock skew instead of part of the setup or hold relationship as done with offsets.

For more information about clock latency, refer to *AN 411: Understanding PLL timing for Stratix II Devices*.

## Timing Exceptions

Timing exceptions allow you to modify the default behavior of the Quartus II Classic Timing Analyzer. This section describes the following timing exceptions:

- Multicycle
- Setup relationship and hold relationship
- Maximum delay and minimum delay
- False paths

Not all timing exceptions presented in this chapter are applicable to the HardCopy® II devices. If you are designing for the HardCopy II device family, refer to the *Timing Constraint for HardCopy II* chapter in the *HardCopy II Handbook*.

### Multicycle

By default, the Quartus II Classic Timing Analyzer performs a single-cycle analysis for all valid register-to-register paths in the design. Multicycle assignments specify the number of clock periods before a source register launches the data or a destination register latches the data. Multicycle assignments adjust the latch or launch edges, which relaxes the required clock setup check or clock hold check between the source and destination register pairs. You can specify multicycles separately for setup and hold, and multicycles can be based on the source clock or destination clock. Apply **Multicycle** exception to time groups, clock nodes, or common clock enables.

#### *Destination Multicycle Setup Exception*

A destination multicycle setup, referred to as a **Multicycle** exception, specifies the minimum number of clock cycles required before a register should latch a value. A **Multicycle** exception changes the latch edge by relaxing the required setup relationship. [Figure 8-11](#) shows a timing diagram for a multicycle path that exists in a design with related clocks, and with the latch edge label for a clock setup check.

By default, the **Multicycle** exception value is 1.

**Figure 8–11. Multicycle Setup**

You can apply **Multicycle** exception between any two registers or between any two clock domains. Use the Tcl command `set_multicycle_assignment`, and the switch `-setup` and `-end`. For example, to apply a **Multicycle** exception of 2 between all registers clocked by source clock `clk_src`, and all registers clocked by destination clock `clk_dst`, enter the following Tcl command:

```
set_multicycle_assignment -setup -end -from clk_src -to clk_dst 2
```

To apply a **Multicycle** exception of 2 between the source register `reg1` and the destination register `reg2`, enter the following Tcl command:

```
set_multicycle_assignment -setup -end -from reg1 -to reg2 2
```

### *Destination Multicycle Hold Exception*

A destination multicycle hold, referred to as a **Multicycle Hold** exception, modifies the latch edge used for a clock hold check for the register-to-register path based on the destination clock. A **Multicycle Hold** exception changes the latch edge by relaxing the required hold relationship. [Figure 8–12](#) shows a timing diagram labeling the latching edge for a clock setup check.

If no **Multicycle Hold** value is specified, the **Multicycle Hold** value defaults to the value of the multicycle exception.

**Figure 8–12. Multicycle Hold**

You can create **Multicycle Hold** exceptions with the Tcl command `set_multicycle_assignment` and the switch `-hold` and `-end`. The following example specifies a **Multicycle Hold** exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -hold -end -from reg1 -to reg2 3
```

By default, the hold multicycle is set to equal that of the setup multicycle value along the same path. For example, if a setup multicycle of 2 has been applied to a register-to-register path without a separate hold multicycle, the hold multicycle value would be set to 2. The default hold multicycle value can also be changed to a value of 1. This forces all paths with a setup multicycle assignment to have a default hold multicycle of 1. To change the default hold multicycle value, in the **Settings** dialog box, click the **More Timing Settings** option.

If your design requires a hold multicycle value not equal to the setup multicycle or 1, you must explicitly apply a hold multicycle assignment to the path.

### *Source Multicycle Setup Exception*

A source multicycle setup, referred to as **Source Multicycle Setup** exception, is used to extend the required delay by adjusting the source clock's launch edge rather than the destination clock's latch edge; for example, multicycle setup. **Source Multicycle** exceptions are useful when the source and destination registers are clocked by related clocks at different frequencies. [Figure 8–13](#) shows an example of a **Source Multicycle** exception with the launch edge labeled for a clock setup check.

**Figure 8–13. Source Multicycle**

You can create **Source Multicycle Setup** exceptions with the Tcl command `set_multicycle_assignment` and the switches `-setup` and `-start`. The following example specifies a **Source Multicycle** exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -setup -start -from reg1 -to reg2 3
```

By default, the hold multicycle is set to equal that of the setup multicycle value along the same path. For example, if a setup multicycle of 2 has been applied to a register-to-register path without a separate hold multicycle, the hold multicycle value would be set to 2. The default hold multicycle value can also be changed to a value of 1. This forces all paths with a setup multicycle assignment to have a default hold multicycle of 1. To change the default hold multicycle value, in the **Settings** dialog box, click the **More Timing Settings** option.

If your design requires a hold multicycle value not equal to the setup multicycle or 1, you must explicitly apply a hold multicycle assignment to the path.

### *Source Multicycle Hold Exception*

The **Source Multicycle Hold** exception modifies the latch edge used for a clock hold check for the register-to-register path based on the source clock. **Source Multicycle Hold** exceptions increase the required hold delay by adding source clock cycles. [Figure 8–14](#) shows an example of a source multicycle hold with launch edge labeled for a clock hold check.

**Figure 8–14. Source Multicycle Hold**

You can create **Source Multicycle Hold** exceptions with the Tcl command `set_multicycle_assignment` and the switch `-setup` and `-start`. The following example specifies a **Source Multicycle Hold** exception of 3 from register `reg1` to register `reg2`:

```
set_multicycle_assignment -hold -start -from reg1 -to reg2 3
```

### *Default Hold Multicycle*

The Quartus II Classic Timing Analyzer sets the hold multicycle value to equal the multicycle value when a multicycle exception has been entered without a corresponding hold multicycle. You can change the behavior with the `DEFAULT_HOLD_MULTICYCLE` assignment. The value of the assignment can either be "ONE" or "SAME AS MULTICYCLE".

The assignment has the following syntax:

```
set_global_assignment -name DEFAULT_HOLD_MULTICYCLE "<value>"
```

### *Clock Enable Multicycle*

For all enable-driven registers, the setup relationship or hold relationship can be modified with the **Clock Enable Multicycle**, **Clock Enable Multicycle Hold**, **Clock Enable Source Multicycle**, or **Clock Enable Multicycle Source Hold**.

The **Clock Enable Multicycle** modifies the latching edge when a clock setup check is performed for all registers driven by the specified clock enables, and the **Clock Enable Multicycle Hold** modifies the latching edge when a clock hold check is performed for all registers driven by the specified clock enable. The **Clock Enable Source Multicycle** modifies the launching edge when a clock setup check is performed for all enabled driven registers, and the **Clock Enable Source Multicycle Hold** modifies the launching edge when a clock hold check is performed for all enabled driven registers.

Clock enable-based multicycle exceptions apply only to registers using dedicated clock enable circuitry. If the enable is synthesized into a logic cell; for example, due to signal prioritization, the multicycle does not apply.

The **Clock Enable Multicycle**, **Clock Enable Multicycle Hold**, **Clock Enable Source Multicycle**, and **Clock Enable Multicycle Source Hold** can be either a single-point or a point-to-point assignment. **Figure 8–15** shows an example of a single-point assignment. In this example, register Reg A has the single-point assignment applied. This has the affect of modifying a register-to-register latching edge whose enable port is driven by register Reg A. All register-to-register paths with enables driven by the single-point assignment are affected, even those driven by different clock sources.

**Figure 8–15. Single-Point Clock Enable Multicycle**

Point-to-point assignments apply to all paths where the source registers' enable ports are driven by the source (`from`) node and the destination registers' enable ports are driven by the destination (`to`) node. **Figure 8–16** shows an example of a point-to-point assignment made to different source and destination registers. In this example, register Reg A is specified as the source, and register Reg B is specified as the destination for the assignment. Only register-to-register paths that have their enables driven by the assigned point-to-point registers have their latching edges modified.

**Figure 8–16. Different Source and Destination Point-to-Point Assignment Clock Enable Multicycle**

Figure 8–17 shows an example of a point-to-point assignment made to the same source and destination register. In this example, register Reg A has been specified as both the source and register for the assignment. Only register-to-register paths that have both the source-enable port and destination-enable port has the latching edge modified by the assigned point-to-point assignment.

**Figure 8–17. Same Source and Destination Point-to-Point Assignment Clock Enable Multicycle**

You can use the `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE` and `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_HOLD` Tcl commands to specify either a **Clock Enable Multicycle** or a **Clock Enable Multicycle Hold** assignment, respectively. The following example specifies a single-point **Clock Enable Multicycle** assignment of 2 ns to `reg1`:

```
set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE 2 -to reg1
```

The following example specifies a point-to-point **Clock Enable Multicycle Hold** assignment of 2 from register `reg1` to register `reg2`:

```
set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_HOLD 2 \  
-from reg1 -to reg2
```

You can use the `set_instance_assignment -name CLOCK_ENABLE_SOURCE_MULTICYCLE` and `set_instance_assignment -name CLOCK_ENABLE_MULTICYCLE_SOURCE_HOLD` Tcl commands to specify either a **Clock Enable Multicycle** or **Clock Enable Multicycle Hold** assignment, respectively. The following example specifies a single-point **Clock Enable Multicycle** assignment of 2 ns to `reg1`:

```
set_instance_assignment -name CLOCK_ENABLE_SOURCE_MULTICYCLE \  
2 -to reg1
```

The following example specifies a point-to-point **Clock Enable Multicycle Hold** assignment of 2 from register `reg1` to register `reg2`:

```
set_instance_assignment -name \  
CLOCK_ENABLE_SOURCE_MULTICYCLE_HOLD 2 -from reg1 -to reg2
```

## Setup Relationship and Hold Relationship

By default, the Quartus II Classic Timing Analyzer determines all setup and hold relationships based on clock settings. The **Setup Relationship** and **Hold Relationship** exceptions allow you to override any default setup or hold relationships. [Example 8-2](#) shows the path details of a register-to-register path that has a 10 ns clock setting applied to the clock signal driving the 2 registers.

**Example 8–2. Default Setup Relationship with 10 ns Clock Setting**

---

```

Info: Slack time is 9.405 ns for clock "data_clk" between source register "reg9" and
destination register "reg10"
Info: Fmax is restricted to 500.0 MHz due to tcl and tch limits
Info: + Largest register to register requirement is 9.816 ns
Info: + Setup relationship between source and destination is 10.000 ns
Info: + Latch edge is 10.000 ns
Info: - Launch edge is 0.000 ns
Info: + Largest clock skew is 0.000 ns
Info: - Micro clock to output delay of source is 0.094 ns
Info: - Micro setup delay of destination is 0.090 ns
Info: - Longest register to register delay is 0.411 ns

```

---

In [Example 8–3](#), a 15 ns **Setup Relationship** exception is applied to the register-to-register path, overriding the default 10 ns setup relationship.

**Example 8–3. Setup Relationship Assignment of 15 ns**

---

```

Info: Slack time is 14.405 ns for clock "data_clk" between source register "reg9" and
destination register "reg10"
Info: Fmax is restricted to 500.0 MHz due to tcl and tch limits
Info: + Largest register to register requirement is 14.816 ns
Info: + Setup relationship between source and destination is 15.000 ns
Info: Setup Relationship assignment value is 15.000 ns between source "reg9" and
destination "reg10"
Info: + Largest clock skew is 0.000 ns
Info: Total interconnect delay = 1.583 ns ( 51.31 % )
Info: - Micro clock to output delay of source is 0.094 ns
Info: - Micro setup delay of destination is 0.090 ns
Info: - Longest register to register delay is 0.411 ns

```

---

You can create a **Setup Relationship** exception with the Tcl command `set_instance_assignment -name SETUP_RELATIONSHIP`. The following example specifies a **Setup Relationship** exception of 5 ns from register reg1 to register reg2:

```
set_instance_assignment -name SETUP_RELATIONSHIP 5ns -from reg1 \
-to reg2
```

You can use **Hold Relationship** exception to override the default hold relationship of any register-to-register paths.

You can use the `set_instance_assignment -name HOLD_RELATIONSHIP` Tcl command to specify a hold relationship assignment. The following example specifies a **Hold Relationship** exception of 1 ns from register reg1 to register reg2:

```
set_instance_assignment -name HOLD_RELATIONSHIP 1ns -from reg1 \
-to reg2
```

## Maximum Delay and Minimum Delay

You can use **Maximum Delay** and **Minimum Delay** assignments to specify delay requirements for pin-to-register, register-to-register, and register-to-pin paths. The **Maximum Delay** assignment overrides any setup relationship for any path. The **Minimum Delay** assignment overrides any hold relationship for any path.

The Quartus II Classic Timing Analyzer ignores the effects of clock skew when checking a design against **Maximum Delay** and **Minimum Delay** assignments.

You can use the `set_instance_assignment -name MAX_DELAY` and `set_instance_assignment -name MIN_DELAY` Tcl commands to specify a **Maximum Delay** assignment or a **Minimum Delay** assignment, respectively. The following example specifies a maximum delay of 2 ns between source register `reg1` and destination register `reg2`:

```
set_instance_assignment -name MAX_DELAY 2ns -from reg1 -to reg2
```

The following example specifies a minimum delay of 1 ns between input pin `data_in` to destination register `dst_reg`:

```
set_instance_assignment -name MIN_DELAY 1ns -from data_in -to \
dst_reg
```

## False Paths

A false path is any path that is not relevant to a circuit's operation, such as test logic. There are several global assignments to cut different classes of paths, such as unrelated clock domains and paths through bidirectional pins, but you can also cut an individual timing path to a specific false path.

The Timing Analyzer provides the following three global options that allow you to remove false paths from your design:

- Cut off feedback from I/O pins
- Cut off read-during-write signal paths
- Cut paths between unrelated clock domains

You can use the `set_global_assignment -name CUT_OFF_IO_PIN_FEEDBACK ON` Tcl command to cut the feedback path when a bidirectional I/O pin is connected directly or indirectly to both the input and output of a latch.

You can use the `set_global_assignment -name CUT_OFF_READ_DURING_WRITE_PATHS ON` Tcl command to cut the path from the write-enable register through memory element to a destination register.

You can use the `set_global_assignment -name CUT_OFF_PATHS_BETWEEN_CLOCK_DOMAINS ON` Tcl command to cut paths between register-to-register where the source and destination clocks are different.

You can use the `set_timing_cut_assignment` Tcl command to cut specific timing paths. In [Figure 8–18](#), the path from `inst1` through the multiplexer to `inst2` is used only for design testing. This false path is not required under normal operation and does not need to be analyzed during static timing analysis. [Figure 8–18](#) shows an example of a false path.

**Figure 8–18. False Path Signal**

To cut the timing path from source register `inst1` to destination register `inst2`, enter the following Tcl command:

```
set_timing_cut_assignment -from inst1 -to inst2
```

You can also use the `set_timing_cut_assignment` Tcl command as a single point assignment. When you use the single point assignment, all fanout of the node is cut. For example, the following Tcl command cuts all timing paths originating for node `src_reg`:

```
set_timing_cut_assignment -to src_reg
```

## I/O Analysis

The I/O analysis performed by the Quartus II Classic Timing Analyzer ensures your Altera FPGA design meets all timing specifications for interfacing with external devices. This section describes assignments relevant to I/O analysis and other I/O analysis features and options available with the Quartus II Classic Timing Analyzer.

### External Input Delay and Output Delay Assignments

External input and output delays represent delays from or to external devices or boards traces. You can make **Input Delay** and **Output Delay** assignments to ensure the Quartus II Classic Timing Analyzer can perform a full system analysis. By providing **Input Delays** and **Output Delays**, the Quartus II Classic Timing Analyzer is able to perform clock setup and clock hold checks for these paths. This also allows other timing assignments, such as multicycle or clock uncertainty, to be applied to input and output paths.

Do not combine individual or global  $t_{SU}$ ,  $t_H$ ,  $t_{PD}$ ,  $t_{CO}$ , minimum  $t_{CO}$ , or minimum  $t_{PD}$  assignments with **Input Delay** or **Output Delay** assignments.

#### *Input Delay Assignment*

External input delays are specified with either **Input Maximum Delay** or **Input Minimum Delay** assignments. Make **Input Maximum Delay** assignments to specify the maximum delay of a signal from an external register to a specified input or bidirectional pin on the FPGA relative to a specified clock source. Make **Input Minimum Delay** assignments to specify the minimum delay of a signal from an external register to a specified input or bidirectional pin on the FPGA relative to a specified clock source.

When performing a clock setup check, the Quartus II Classic Timing Analyzer adds the **Input Maximum Delay** assignment value to the data arrival time (or subtracts the assignment value from the point-to-point requirement).

When performing a clock hold check, the Quartus II Classic Timing Analyzer adds the **Input Minimum Delay** assignment value to the data arrival time (or subtracts the assignment value from the point-to-point requirement).

The value of the input delay assignment usually represents the sum of the  $t_{CO}$  of the external device, the actual board delay to the input pin of the Altera device, and the board clock skew.

The **Input Minimum Delay** defaults to the **Input Maximum Delay** and the **Input Maximum Delay** defaults to the **Input Minimum Delay** if only one is specified.

For example, the Input Maximum Delay and Input Minimum Delay can be used to model the delay associated with an external device driving into an Altera FPGA. Figure 8–19 shows an example of the input delay path. For Figure 8–19, the Input Maximum Delay can be calculated as shown in Equation 19.

$$(19) \quad \text{Input Maximum Delay} = \text{External Device Board Clock Path} + \text{External Device } t_{C0} + \text{External Device to Altera Device Board Delay} - \text{External Clock Path to Altera Device}$$

**Figure 8–19. Input Delay**

Use the Tcl command `set_input_delay` to specify an input delay. The following example specifies an **Input Maximum Delay** assignment of 1.5 ns from clock node `clk` to input pin `data_in`:

```
set_input_delay -clk_ref clk -to "data_in" -max 1.5ns
```

The following example specifies an **Input Minimum Delay** assignment of 1 ns from clock node `clk` to input pin `data_in`:

```
set_input_delay -clk_ref clk -to "data_in" -min 1ns
```

When using **Input Delay** assignments, specify a particular clock reference. The clock reference is the clock that feeds the external register's clock port that feeds the Altera device. This allows the Quartus II Classic Timing Analyzer to perform the proper analysis for the input path.

The  $t_{SU}$ ,  $t_H$ ,  $t_{PD}$ , and  $\min t_{PD}$  timing paths reported for input pins, where input delay internal to the Altera FPGA assignments has been applied, include only the data delay from these pins and do not account for any clock setup relationships, clock hold relationships, or slack.

### Output Delay Assignment

You can specify external output delays with either **Output Maximum Delay** or **Output Minimum Delay** assignments. Make **Output Maximum Delay** assignments to specify the maximum delay of a signal from the specified FPGA output pin to an external register, relative to a specified clock source. Make **Output Minimum Delay** assignments to specify the minimum delay of a signal from the specified FPGA output pin to an external register relative to a specified clock source.

When performing a clock setup check, the Quartus II Classic Timing Analyzer subtracts the **Output Maximum Delay** assignment value from the data required time (or subtracts the assignment value from the point-to-point requirement).

When performing a clock hold check, the Quartus II Classic Timing Analyzer subtracts the **Output Minimum Delay** assignment value from the data required time (or subtracts the assignment value from the point-to-point requirement).

The value of this assignment usually represents the sum of the  $t_{SU}$  of the external device, the actual board delay from the output pin of the Altera device, and the board clock skew.

The **Output Minimum Delay** default value is the same as the **Output Maximum Delay**, and the **Output Maximum Delay** default value is the same as the **Output Minimum Delay** if only one is specified.

For example, use the **Output Maximum Delay** and **Output Minimum Delay** to model the delay associated with outputs for an Altera FPGA driving into an external device. [Figure 8–20](#) shows an example of an output delay path. For [Figure 8–20](#) the **Output Maximum Delay** can be calculated, as shown in [Equation 20](#).

$$(20) \quad \text{Output Maximum Delay} = \text{Altera Device to External Device Board Delay} + \frac{\text{External Device } t_{SU} + \text{External Clock Path to Altera Device}}{\text{External Device Board Clock Path}}$$

**Figure 8–20. Output Delay**

The Tcl command `set_output_delay` specifies an **Output Delay** assignment. The following example specifies an **Output Maximum Delay** assignment of 2 ns from clock `clk` to output pin `data_out`:

```
set_output_delay -clk_ref clk -to data_out -max 2ns
```

The following example specifies an **Output Minimum Delay** assignment of 1 ns from clock `clk` to output pin `data_out`:

```
set_output_delay -clk_ref clk -to data_out -min 1ns
```

When using output delay assignments, specify a specific clock reference. The clock reference is the clock that feeds the external register's clock port that is fed by the Altera device. This allows the Quartus II Classic Timing Analyzer to perform the correct static timing analysis on the output path.

 The  $t_{CO}$ , minimum  $t_{CO}$ ,  $t_{PD}$ , and minimum  $t_{PD}$  timing paths reported for output pins, where output delay assignments have been applied include only the data delay internal to the Altera FPGA to those pins, and do not account for any clock setup relationships, clock hold relationships, or slack.

## Virtual Clocks

You can use virtual clocks to model clock signals outside of the Altera FPGA, that is, clocks that do not directly drive anything within the Altera FPGA. For example, you can use a virtual clock to model a clock signal feeding an external output register that feeds the Altera FPGA.

Using the `-virtual` option of the `create_base_clock` Tcl command specifies a virtual clock assignment.

 Before you can use virtual clock for either an input or output delay assignment, the virtual clock must have the **Virtual Clock Reference** assignment enabled for the virtual clock setting.

The code in [Example 8-4](#) creates a virtual clock named `virt_clk`, with a 200 MHz requirement, and uses the virtual clock setting as the clock reference for the input delay assignment.

---

**Example 8-4. Creating a Virtual Clock Named `virt_clk`**

```
#create the virtual clock setting
create_base_clock -fmax 200MHz -virtual virt_clk

#enable the virtual clock reference for the virtual clock setting
set_instance_assignment -name VIRTUAL_CLOCK_REFERENCE On -to virt_clk

#use the virtual clock setting as the clock reference for the input delay assignment
set_input_delay -clk_ref virt_clk -to data_in -max 2ns
```

---

## Asynchronous Paths

The Quartus II Classic Timing Analyzer can analyze asynchronous signals that connect to the clear, preset, or load ports of a register. This section explains how the Quartus II Classic Timing Analyzer analyzes asynchronous paths.

### Recovery and Removal

Recovery time is the minimum length of time an asynchronous control signal; for example, clear and preset, must be stable before the active clock edge. Removal time is the minimum length of time an asynchronous control signal must be stable after the active clock edge. The **Enable Recovery/Removal** analysis option reports the results of recovery and removal checks for paths that end at an asynchronous clear, preset, or load signal of a register.

Enable the recovery and removal analysis with the following Tcl command:

```
set_global_assignment -name ENABLE_RECOVERY_REMOVAL_ANALYSIS ON
```

With this option enabled, the Quartus II Classic Timing Analyzer reports the result of the recovery analysis and removal analysis.

By default, the recovery and removal analysis is disabled. You should enable this option for all designs that contain asynchronous controls signals.

### Recovery Report

When you set `ENABLE_RECOVERY_REMOVAL_ANALYSIS` to **ON**, the Quartus II Classic Timing Analyzer determines the recovery time as the minimum amount of time required between an asynchronous control signal becoming inactive and the next active clock edge, compares this to your design, and reports the results as slack. The Recovery report alerts you to conditions where an active clock edge occurs too soon after the asynchronous input becomes inactive, rendering the register's data uncertain.

The recovery slack time calculation is similar to the calculation for clock setup slack, which is based on data arrival time and data required time except for asynchronous control signals. If the asynchronous control is registered, the Quartus II Classic Timing Analyzer calculates the recovery slack time using [Equations 21](#) through [23](#).

- (21)  $\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$
- (22)  $\text{Data Arrival Time} = \text{Launch Edge} + \text{Longest Clock Path to Source Register} + \text{micro } t_{\text{CO}} \text{ of Source Register} + \text{Longest Register-to-Register Delay}$
- (23)  $\text{Data Required Time} = \text{Latch Edge} + \text{Longest Clock Path to Source Register} + \text{micro } t_{\text{SU}} \text{ of Destination Register}$

[Example 8-5](#) shows recovery time as reported by the Timing Analyzer.

---

#### **Example 8-5. Recovery Time Reporting for a Registered Asynchronous Reset Signal**

```
Info: Slack time is 8.947 ns for clock "a_clk" between source register "async_reg1" and destination register "reg_1"
Info: Requirement is of type recovery
Info: - Data arrival time is 4.028 ns
Info: + Launch edge is 0.000 ns
Info: + Longest clock path from clock "a_clk" to source register is 3.067 ns
Info: + Micro clock to output delay of source is 0.094 ns
Info: + Longest register to register delay is 0.867 ns
Info: + Data required time is 12.975 ns
Info: + Latch edge is 10.000 ns
Info: + Shortest clock path from clock "a_clk" to destination register is 3.065 ns
Info: - Micro setup delay of destination is 0.090 ns
```

---

If the asynchronous control is not registered, the Quartus II Classic Timing Analyzer uses [Equations 24](#) through [Equations 26](#) to calculate the recovery slack time.

- (24)  $\text{Recovery Slack Time} = \text{Data Required Time} - \text{Data Arrival Time}$

- (25)  $\text{Data Arrival Time} = \text{Launch Edge} + \text{Maximum Input Delay} + \text{Maximum Pin-to-Register Delay}$
- (26)  $\text{Data Required Time} = \text{Latch Edge} + \text{Shortest Clock Path to Destination Register Delay} - \text{micro } t_{\text{SU}} \text{ of Destination Register}$

Example 8–6 shows recovery time as reported by the Timing Analyzer.

---

**Example 8–6. Recovery Time Reporting for a Non-Registered Asynchronous Reset Signal**

Info: Slack time is 8.744 ns for clock "a\_clk15" between source pin "a\_arst2" and destination register "inst5"

```

Info: Requirement is of type recovery
Info: - Data arrival time is 4.787 ns
      Info: + Launch edge is 0.000 ns
      Info: + Max Input delay of pin is 1.500 ns
      Info: + Max pin to register delay is 3.287 ns
Info: + Data required time is 13.531 ns
Info: + Latch edge is 10.000 ns
Info: + Shortest clock path from clock "a_clk15" to destination register
is 3.542 ns
Info: - Micro setup delay of destination is 0.011 ns
    
```

---

If the asynchronous reset signal is from a device pin, an **Input Maximum Delay** assignment must be made to the asynchronous reset pin for the Quartus II Classic Timing Analyzer to perform recovery analysis on that path.

### Removal Report

When you set `ENABLE_RECOVERY_REMOVAL_ANALYSIS` to **ON**, the Quartus II Classic Timing Analyzer determines the removal time as the minimum amount of time required between an active clock edge that occurs while an asynchronous input is active, and the deassertion of the asynchronous control signal. The Quartus II Classic Timing Analyzer then compares this to your design and reports the results as slack. The Removal report alerts you to a condition in which an asynchronous input signal goes inactive too soon after a clock edge, thus rendering the register's data uncertain.

The removal time slack calculation is similar to the one used to calculate clock hold slack, which is based on data arrival time and data required time except for asynchronous control signals. If the asynchronous control is registered, the Quartus II Classic Timing Analyzer uses [Equations 27 through 29](#) to calculate the removal slack time.

- (27)  $\text{Removal Slack Time} = \text{Data Arrival Time} - \text{Data Required Time}$

- (28) Data Arrival Time = Launch Edge + Shortest Clock Path from Source Register Delay +  
micro  $t_{CO}$  of Source Register + Shortest Register-to-Register Delay
- (29) Data Required Time = Latch Edge + Longest Clock Path to Destination Register Delay +  
micro  $t_H$  of Destination Register

**Example 8-7** shows removal time as reported by the Quartus II Classic Timing Analyzer.

---

**Example 8-7. Removal Time Reporting for a Registered Asynchronous Reset Signal**

```
Info: Minimum slack time is 814 ps for clock "a_clk" between source register "async_reg1"
and destination register "reg_1"
Info: Requirement is of type removal
Info: + Data arrival time is 4.028 ns
Info: + Launch edge is 0.000 ns
Info: + Shortest clock path from clock "a_clk" to source register is 3.067 ns
Info: + Micro clock to output delay of source is 0.094 ns
Info: + Shortest register to register delay is 0.867 ns
Info: - Data required time is 3.214 ns
Info: + Latch edge is 0.000 ns
Info: + Longest clock path from clock "a_clk" to destination register is 3.065 ns
Info: + Micro hold delay of destination is 0.149 ns
```

---

If the asynchronous control is not registered, the Quartus II Classic Timing Analyzer uses [Equations 30](#) through [32](#) to calculate the removal slack time.

- (30) Removal Slack Time = Data Arrival Time – Data Required Time
- (31) Data Arrival Time = Launch Edge + Input Minimum Delay of Pin +  
Minimum Pin-to-Register Delay
- (32) Data Required Time = Latch Edge + Longest Clock Path to Destination Register Delay +  
micro  $t_H$  of Destination Register

Example 8–8 shows removal time as reported by the Quartus II Classic Timing Analyzer.

---

**Example 8–8. Removal Time Reporting for a Non-Registered Asynchronous Reset Signal**

```
Info: Minimum slack time is 1.131 ns for clock "a_clk15" between source pin "a_arst2" and
destination register "inst5"
    Info: Requirement is of type removal
    Info: + Data arrival time is 4.787 ns
Info: + Launch edge is 0.000 ns
Info: + Min Input delay of pin is 1.500 ns
Info: + Min pin to register delay is 3.287 ns
    Info: - Data required time is 3.656 ns
Info: + Latch edge is 0.000 ns
Info: + Longest clock path from clock "a_clk15" to destination register
is 3.542 ns
    Info: + Micro hold delay of destination is 0.114 ns
```

---

If the asynchronous reset signal is from a device pin, an **Input Minimum Delay** assignment must be made to the asynchronous reset pin for the Quartus II Classic Timing Analyzer to perform a removal analysis on this path.

## Skew Management

Clock skew is the difference in the arrival times of a clock signal at two different registers, which can be caused by path length differences between two clock paths, or by using gated or rippled clocks. As clock periods become shorter and shorter, the skew between data arrival times and clock arrival times becomes more significant. The Quartus II Classic Timing Analyzer provides two assignments for analyzing and constraining skew for data and clock signals.

### Maximum Clock Arrival Skew

Make **Maximum Clock Arrival Skew** assignments to specify the maximum allowable clock arrival skew between a clock signal and various destination registers. The Quartus II Classic Timing Analyzer compares the longest clock path to the registers' clock port and the shortest clock path to the registers' clock port to determine if your maximum clock arrival skew is achieved. Maximum clock arrival skew is calculated using [Equation 33](#).

$$(33) \quad \text{Maximum Clock Arrival Skew} = \text{Longest Clock Path} - \text{Shortest Clock Path}$$

For example, if the delay from clock pin `clk` to the clock port of register `reg1` is 1.0 ns, and the delay from clock pin `clk` to the clock port of register `reg2` is 3.0 ns, as shown in [Figure 8–21](#), the Quartus II Classic Timing Analyzer provides a clock skew slack time of 2.0 ns.

**Figure 8–21. Clock Arrival Paths**

You should apply the **Maximum Clock Arrival Skew** assignment to a clock node and a group of registers. When you make a **Maximum Clock Arrival Skew** assignment, the Fitter attempts to satisfy the skew requirement.

You can use the `set_instance_assignment -name max_clock_arrival_skew Tcl` command to specify a **Maximum Clock Arrival Skew** assignment. The following example specifies a maximum clock arrival skew of 1 ns from clock signal `clk` to the bank of registers matching `reg*`:

```
set_instance_assignment -name max_clock_arrival_skew 1ns -from clk -to reg*
```

## Maximum Data Arrival Skew

Make **Maximum Data Arrival Skew** assignments to specify the maximum allowable data arrival skew to various destination registers or pins. The Quartus II Classic Timing Analyzer compares the longest data arrival path to the shortest data arrival path to determine if your specified maximum data arrival skew is achieved. Maximum data arrival skew is calculated using [Equation 34](#).

$$(34) \quad \text{Maximum Data Arrival Skew} = \text{Longest Data Arrival Path} - \text{Shortest Data Arrival Path}$$

For example, if the data arrival time to output pin `out1` is 2.0 ns, the data arrival time to output pin `out2` is 1.5 ns, and the data arrival time to output pin `out3` is 1.0 ns, as shown in [Figure 8–22](#), the Quartus II Classic Timing Analyzer provides a maximum data arrival skew slack time of 1.0 ns.

**Figure 8–22. Data Arrival Paths**

 When you make a **Maximum Data Arrival Skew** assignment, the Fitter attempts to satisfy the skew requirement.

You can use the `set_instance_assignment -name max_data_arrival_skew Tcl` command to specify a maximum data arrival skew value. The following example specifies a maximum data arrival skew of 1 ns from clock signal `clk` to the bank of output pins `dout`:

```
set_instance_assignment -name max_data_arrival_skew 1ns -from clk -to dout[*]
```

## Generating Timing Analysis Reports with `report_timing`

The Quartus II Classic Timing Analyzer includes the `report_timing Tcl` command for generating text-based timing analysis reports. You can customize the output of `report_timing` using multiple switches that allow the generation of both detailed and general timing reports on any path in the design.

 The `report_timing Tcl` command is available in the `quartus_tan` executable.

Prior to using the `report_timing Tcl` command, you must open a Quartus II project and create a timing netlist. For example, the following two Tcl commands accomplish this:

```
project_open my_project
create_timing_netlist
```

The report\_timing Tcl command provides -from and -to switches for filtering specific source and destination nodes. For example, the following report\_timing Tcl command reports all clock setup paths, with the switch -clock\_setup, between registers src\_reg\* and dst\_reg\*. The -npaths 20 switch limits the report to 20 paths.

```
report_timing -clock_setup -from src_reg* -to dst_reg* -npaths 20
```

The switches -clock\_filter and -src\_clock\_filter are also available for filtering based on specific clock sources. For example, the following report\_timing Tcl command reports all clock setup paths where the destination registers are clocked by clk:

```
report_timing -clock_setup -clock_filter clk
```

The following example reports clock setup paths where the destination registers are clocked by clk, and the source registers are clocked by src\_clock.

```
report_timing -clock_setup -clock_filter clk -src_clock_filter \
src_clk
```

[Example 8-9](#) is an example script that can be sourced by the quartus\_tan executable:

---

**Example 8-9. Source for the quartus\_tan Executable**

```
# Open a project
project_open my_project
# Always create the netlist first
create_timing_netlist
# List clock setup paths for clock clk
# from registers abc* to registers xyz*
report_timing -clock_setup -clock_filter clk -from abc* -to xyz*
# List the top 5 pin-to-pin combinational paths
report_timing -tpd -npaths 5
# List the top 5 pin-to-pin combinational paths and
# write output to an out.tao file
report_timing -tpd -npaths 5 -file out.tao
# Compute min tpd and append results to existing out.tao
report_timing -min_tpd -npaths 5 -file out.tao -append
# Show longest path (register to register data path) between a* and b*
report_timing -longest_paths -npaths 1
delete_timing_netlist
project close
```

---

## Other Timing Analyzer Features

The Quartus II Classic Timing Analyzer provides many features for customizing and increasing the efficiency of static timing analysis, including:

- Wildcard assignments
- Assignment groups
- Fast corner analysis
- Early timing estimation
- Timing constraint checker
- Latch analysis

### Wildcard Assignments

To simplify the tasks of making assignments to many node assignments, the Quartus II software accepts the \* and ? wildcard characters. Use these wildcard characters to reduce the number of individual assignments you need to make for your design.

The "\*" wildcard character matches any string. For example, given an assignment made to a node specified as `reg*`, the Quartus II Classic Timing Analyzer searches and applies the assignment to all design nodes that match the prefix `reg` with none, one, or several characters following, such as `reg1`, `reg[2]`, `regbank`, and `reg12bank`.

The "?" wildcard character matches any single character. For example, given an assignment made to a node specified as `reg?`, the Quartus II Classic Timing Analyzer searches and applies the assignment to all design nodes that match the prefix `reg` and any single character following, such as `reg1`, `rega`, and `reg4`.

### Assignment Groups

Assignment groups, also known as time groups, allow you to define a custom group of nodes to which you can assign timing assignments. You can also exclude specific nodes, wildcards, and time groups from a time group.

Use the `timegroup Tcl` command to create an assignment group. The following example creates an assignment group `srcgrp` and adds nodes with names that match `src1*` to the group:

```
timegroup srcgrp -add_member src1*
```

For example, [Figure 8–23](#) has false paths between source register `reg1` and destination register bank `sram_reg`, `external_reg`, `internal_reg`, and `cam_reg` that need to be cut. Without the use of assignment groups, the assignments required are:

```
set_timing_cut_assignment -from reg1 to sram_reg
set_timing_cut_assignment -from reg1 to external_reg
set_timing_cut_assignment -from reg1 to internal_reg
set_timing_cut_assignment -from reg1 to cam_reg
```

**Figure 8–23. False Path**

With an assignment group called `dst_reg_bank`, the assignments required are:

```
#create a time group called dst_reg
timegroup dst_reg_bank -add_member sram_reg
timegroup dst_reg_bank -add_member external_reg
timegroup dst_reg_bank -add_member internal_reg
timegroup dst_reg_bank -add_member cam_reg
#cut timing paths
set_timing_cut_assignment -from reg1 to dst_reg_bank
```

Once an assignment group has been defined, applicable timing assignment can be made to the time group without redefining the assignment group.

Assigning individual nodes to time groups and applying timing assignments to these time groups can improve the performance of the Quartus II Classic Timing Analyzer.

## Fast Corner Analysis

Fast Corner Analysis uses timing models generated under best-case conditions (voltage, process, and temperature) for the fastest speed-grade device.

Both Fast Corner and Slow Corner static timing analysis reports are saved to the `<project name>.tan.rpt` file, potentially overwriting previous timing analysis reports. To preserve a copy of your reports, save the file with a new name before the next compilation or static timing analysis, or use the Combined Fast/Slow Analysis report feature.

The Quartus II software also reports minimum delay checks after a slow corner (default) analysis. These results are generated by reporting minimum delay checks using worst-case timing models.

To perform fast corner static timing analysis with the best-case timing models, you can use the switch `--fast_model=on` with the `quartus_tan` executable. The following Tcl command enables the fast timing models:

```
quartus_tan <project_name> --fast_model=on
```

## Early Timing Estimation

The majority of Quartus II software compilation time is consumed by the place-and-route process used to obtain optimal design results. To accelerate the design process for large designs, the Quartus II software provides **Early Timing Estimation**. This feature provides a quick static timing analysis in a fraction of the time required for a full compilation by performing a preliminary place-and-route on the design without full optimizations, which reduces total compile time by up to five times compared to a fully fitted design.

An **Early Timing Estimate** fit is not fully optimized or legally routed. The timing delay report is only an estimate. Typically, the estimated delays are within 10% of those obtained with a full fit when the realistic setting is used.

The **Early Timing Estimate** has three settings for generating timing estimates: Realistic, Optimistic, and Pessimistic. [Table 8–1](#) describes these settings.

<b>Setting</b>	<b>Description</b>
<b>Realistic</b> (default setting: estimates final timing using standard fitting)	Generates timing estimates that are likely to be closest to full compilation results.
<b>Optimistic</b> (estimates best-case final timing)	Generates timing estimates that are unlikely to be exceeded by full compilation.
<b>Pessimistic</b> (estimates worst-case final timing)	Generates timing estimates that are likely to be exceeded by full compilation.

To use the **Early Timing Estimate** feature, enter the following Tcl command when performing a fit:

```
quartus_fit --early_timing_estimate[=<realistic|optimistic|pessimistic>]
```

After **Early Timing Estimate** is complete, a full timing report is generated based on the early placement and routing delays. In addition, you can view the preliminary logic placement in the Timing Closure floorplan. The early timing placement allows you to perform initial placement and view the timing interaction of various placement topology.

## Timing Constraint Checker

Altera recommends that you enter all timing constraints into the Quartus II software prior to performing a full compilation. This ensures that the Fitter targets the correct timing requirements and ensures that the Quartus II Classic Timing Analyzer reports the correct violations for all timing paths in the design. To ensure that all constraints have been applied to design nodes, the **Timing Constraint Check** feature reports all unconstraint paths in your design. [Example 8–10](#) shows the timing constraint check summary generated after a full compilation.

**Example 8–10. Timing Constraint Check Summary**

```

+-----+
; Timing Constraint Check Summary ;
+-----+
; Timing Constraint Check Status ; Analyzed - Tue Feb 28 11:42:31 2006 ;
; Quartus II Version ; 6.1 Internal Build 143 02/20/2006 SJ Full Version ;

```

To perform a timing constraint check, use the switch `--check_constraints` with the `quartus_tan` executable. The following Tcl command performs a timing constraint check on both setup and hold on the design system:

```
quartus_tan block1 --check_constraints=both
```

**Latch Analysis**

Latches are implemented in the Quartus II software as look-up-tables (LUTs) feeding back onto themselves. The Quartus II Classic Timing Analyzer can analyze these latches as synchronous elements rather than as combinational elements. The clock enables are analyzed as inverted clocks. The Quartus II Classic Timing Analyzer reports the results of setup and hold analysis on these latches.

You can turn on the **Analyze Latches As Synchronous Elements** option with the following Tcl command:

```
set_global_assignment -name ANALYZE_LATCHES_AS_SYNCHRONOUS_ELEMENTS ON
```

## Timing Analysis Using the Quartus II GUI

In addition to the extensive scripting support available in the Quartus II Classic Timing Analyzer, the Quartus II software provides the Assignment Editor and other user interface tools, giving you access to the Quartus II Classic Timing Analyzer features and assignments.

### Assignment Editor

The Assignment Editor is a spreadsheet-style interface used for adding, modifying, and deleting timing assignments.

To make timing assignments in the Assignment Editor, choose **Timing** from the category list to cause the Assignment Name column to display only timing assignments. Double-click <<new>> in the **Assignment Name** field, the **Assignment Name** list displays. [Figure 8–24](#) shows the Assignment Editor with the Assignment Name list displaying timing assignment types.

**Figure 8–24. Assignment Editor**

For more information about the Assignment Editor, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

## Timing Settings

You can specify delay requirements and clock settings with the **Timing Analysis Settings** page of the **Settings** dialog box.

To access this page, on the Assignments menu, click **Settings**. In the Category list, click the  icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Click **Classic Timing Analyzer Settings**. The **Classic Timing Analysis Settings** page displays (Figure 8–25).

**Figure 8–25. Timing Analysis Settings Dialog Box**

### *Clock Settings Dialog Box*

You can create or modify base clock settings or derived clock settings using the **Clock Settings** dialog box. To access this page, on the Assignments menu, click **Settings**. In the Category list, click the  icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Click on **Classic Timing Analyzer Settings**. The **Timing Analysis Settings** page displays. Under **Clock Settings**, click **Individual Clocks**. The **Individual Clock** dialog box is shown (Figure 8–26).

**Figure 8–26. Individual Clocks Dialog Box**

Click the **New** button in the **Individual Clocks** dialog box to access the **New Clock Settings** dialog box and create a base or derived clock setting (Figure 8–27).

**Figure 8–27. New Settings Dialog Box**

*More Timing Settings Dialog Box*

On the **Timing Analysis Settings** page of the **Settings** dialog box, click **More Settings** to display the **More Timing Settings** dialog box (Figure 8–28). The **More Timing Settings** dialog box provides access to many global timing analysis options.

Figure 8–28. More Timing Settings Dialog Box

## Timing Reports

The Quartus II Classic Timing Analyzer report is a section of the Compilation Report containing the static timing analysis results. The Quartus II Classic Timing Analyzer report includes clock setup and clock hold measurements for all clock sources. The report also shows  $t_{CO}$  for all output pins,  $t_{SU}$  and  $t_H$  for all input pins, and  $t_{PD}$  for any pin-to-pin combinational paths in the design. Other reports are created for different analyses and device features.

In the **Settings** dialog box, you can specify the range of information to be reported in the timing analysis of the Compilation Report. To access this page, on the Assignments menu, click **Settings**. In the Category list, click the  icon next to **Timing Analysis Settings** to expand the folder. (Be sure that the **Use Classic Timing Analyzer during compilation** radio button is turned on.) Click the  icon next to **Classic Timing Analyzer Settings** to expand the folder. Click **Classic Timing Analyzer Reporting**. The **Classic Timing Analyzer Reporting** dialog box (Figure 8–29) appears.

Figure 8–29. Classic Analyzer Reporting

If there are no timing assignments for the design, the Quartus II Classic Timing Analyzer does not generate slack reports for any detected clock nodes. The Quartus II Classic Timing Analyzer only reports slack measurements for pins with individual or global  $t_{SU}$ ,  $t_{H}$ , or  $t_{CO}$  assignments. A positive slack indicates the margin by which the path surpasses the clock timing requirements. A negative slack indicates the margin by which the path fails the clock timing requirements.

This Timing Analysis report is also available in text format located in the design directory with the file name `<revision name>.tan.rpt`.

In the Compilation Report, select an analysis type under the Timing Analyzer folder to display the analysis report; for example, Clock Setup or Clock Hold. Figure 8–30 shows an example of a Clock Setup report for clock signal `clk`.

Figure 8–30. Timing Analysis Report

	Slack	Actual fmax (period)	From	To	From Clock	To Clock	Required Setup Relationship	Required Longest P2P Time
1	9.049 ns	91.32 MHz ( period = 10.951 ns )	state_minst1filter.tap4	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
2	9.664 ns	96.75 MHz ( period = 10.336 ns )	state_minst1filter.tap3	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
3	9.796 ns	98.00 MHz ( period = 10.204 ns )	state_minst1filter.tap2	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
4	10.239 ns	102.45 MHz ( period = 9.761 ns )	taps:instbn[2]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
5	10.283 ns	102.91 MHz ( period = 9.717 ns )	taps:instbn[5]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
6	10.319 ns	103.30 MHz ( period = 9.681 ns )	state_minst1filter.tap4	acc:inst3result[10]	clk	clk	20,000 ns	19,798 ns
7	10.391 ns	104.07 MHz ( period = 9.609 ns )	taps:instbn[0]	acc:inst3result[11]	clk	clk	20,000 ns	19,773 ns
8	10.480 ns	105.04 MHz ( period = 9.520 ns )	taps:instbn_2[0]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
9	10.523 ns	105.52 MHz ( period = 9.477 ns )	taps:instbn_1[1]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
10	10.757 ns	108.19 MHz ( period = 9.243 ns )	taps:instbn_1[2]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
11	10.768 ns	108.32 MHz ( period = 9.232 ns )	taps:instbn[4]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
12	10.851 ns	109.30 MHz ( period = 9.149 ns )	taps:instbn_2[2]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
13	10.934 ns	110.30 MHz ( period = 9.066 ns )	state_minst1filter.tap3	acc:inst3result[10]	clk	clk	20,000 ns	19,798 ns
14	10.996 ns	111.06 MHz ( period = 9.004 ns )	taps:instbn_1[4]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns
15	11.066 ns	111.93 MHz ( period = 8.934 ns )	state_minst1filter.tap2	acc:inst3result[10]	clk	clk	20,000 ns	19,798 ns
16	11.110 ns	112.49 MHz ( period = 8.890 ns )	taps:instbn[3]	acc:inst3result[11]	clk	clk	20,000 ns	19,798 ns

## Advanced List Path

The **Advanced List Paths** dialog box provides detailed information about a specific path, such as interconnect and cell delays between any two valid register-to-register paths (Figure 8–31).

The **Advanced List Paths** dialog box allows you to select the type of paths you want listed. For example, you can obtain detailed information for Clock Setup and Clock Hold for a specific clock. In addition, the Tcl command field in the window matches the equivalent Tcl command you can use in either a custom Tcl script or in the Tcl console.

**Figure 8–31. Advanced List Paths Dialog Box**

You can perform a list path command directly from the Timing Analysis report. To do this, right click a path and click **List Path** (Figure 8–32). To launch the **Advanced List Paths** dialog box, right-click a path and in the menu that appears, and select **Advanced List Paths**.

The **Advanced List Paths** dialog box displays only paths that are visible in the Timing Analysis report. To increase the amount of paths reported by the Quartus II Classic Timing Analyzer, on the Assignments menu, click **Timing Analysis Settings**. In the **Category** list, expand **Timing Analysis Settings** and select **Timing Analyzer Reporting**. In the **Timing Analyzer Reporting** page, specify the range of information to be reported by the Quartus II Classic Timing Analyzer.

Both the **Advanced List Paths** and the **List Path** commands display the path information in the **System** message window.

**Figure 8–32. List Path in the Message Window**

If the **Combined Fast/Slow Timing** option is enabled, the List Path Tcl command displays only path delays reported in the Slow Model section.

## Early Timing Estimate

To start an Early Timing Estimate, on the Processing menu, point to Start and click **Start Early Timing Estimate**. To specify the **Early Timing Estimate** mode, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Processes Settings**, select **Early Timing Estimate** and click the desired timing estimate mode. For more information about the Early Timing Estimate feature, refer to “[Early Timing Estimation](#)” on page 8–40.

## Assignment Groups

To define, modify, and delete assignment groups, also known as time groups, from a single dialog box, on the Assignments menu, click **Assignment (Time) Groups**. The **Assignment Groups** dialog box displays (Figure 8–33).

**Figure 8–33. Assignment Groups Dialog Box**

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

Refer to the *Scripting Reference Manual* to view this information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## Creating Clocks

There are two Tcl commands that allow you to define clocks in a design, `create_base_clock` and `create_relative_clock`.

### Base Clocks

Use the `create_base_clock` Tcl command to define a base clock:

```
create_base_clock [-h | -help] [-long_help] -fmax <fmax> [-duty_cycle <integer>] \
[-virtual] [-target <name>] [-no_target] [-entity <entity>] [-disable] \
[-comment <comment>] <clock_name>
```

To define a base clock setting named `sys_clk` with a 100 MHz requirement applied to node `clk_src`, enter the following Tcl command:

```
create_base_clock -fmax 100MHz -target clk_src sys_clk
```

### Derived Clocks

Use the `create_relative_clock` Tcl command to define a relative clock:

```
create_relative_clock [-h | -help] [-long_help] -base_clock <Base clock> \
[-duty_cycle <integer>] [-multiply <integer>] [-divide <integer>] [-offset <offset>] \
[-phase_shift <integer>] [-invert] [-virtual] [-target <name>] [-no_target] \
[-entity <entity>] [-disable] [-comment <comment>] <clock_name>
```

To define a relative clock named `aux_clk` based upon base clock setting `sys_clk` with a multiplication factor of 2 applied to node `rel_clk`, enter the following Tcl command:

```
create_relative_clock -base_clock sys_clk -multiply 2 -target rel_clk aux_clk
```

## Clock Latency

You can use the `set_clock_latency` Tcl command to create either an early or late clock latency assignment:

```
set_clock_latency [-h | -help] [-long_help] [-early] [-late] -to <to> [<value>]
```

To apply an early clock latency of 1 ns and a late clock latency of 2 ns to clock node `clk`, enter the following Tcl commands:

```
set_clock_latency -early -to clk 2ns
```

## Clock Uncertainty

You can use the `set_clock_uncertainty` Tcl command to create clock uncertainty assignments as shown in the following example:

```
set_clock_uncertainty [-h] [-help] [-long_help [-from <source clock name> ] -to  
<destination clock name> [-setup] [-hold] [-remove] [-disable] [-comment <comment>] <value>
```

To apply a clock setup uncertainty of 50 ps between source clock node `clk_src` and destination clock node `clk_dst`, enter the following Tcl command:

```
set_clock_uncertainty -from clk_src -to clk_dst -setup 50ps
```

To apply a clock hold uncertainty of 25 ps between to clock node `clk_sys`, enter the following Tcl command:

```
set_clock_uncertainty -to clk_sys -setup 25ps
```

## Cut Timing Paths

You can use the `set_timing_cut_assignment` Tcl command to create cut timing assignments:

```
set_timing_cut_assignment [-h | -help] [-long_help] [-from <from_node_list>]  
[-to <to_node_list>] [-remove] [-disable] [-comment <comment>]
```

To cut the timing path from source register `reg1` to destination register `reg2`, enter the following Tcl command:

```
set_timing_cut_assignment -from reg1 -to reg2
```

## Input Delay Assignment

You can use the Tcl command `set_input_delay` to create input delay assignments:

```
set_input_delay [-h | -help] [-long_help] [-clk_ref <clock>] -to <input_pin> [-min] [-max]  
[-clock_fall] [-remove] [-disable] [-comment <comment>] [<value>]
```

To apply an input maximum delay of 2 ns to an input pin named `data_in` that feeds a register clocked by clock source `clk`, enter the following Tcl command:

```
set_input_delay -clk_ref clk -to data_in -max 2ns
```

## Maximum and Minimum Delay

The following Tcl commands create the **Maximum Delay** and **Minimum Relationship** assignments, respectively:

```
set_instance_assignment -name MAX_delay <value> -from <node> -to <node>
set_instance_assignment -name MIN_delay <value> -from <node> -to <node>
```

To apply a **Maximum Delay** of 8 ns and a minimum of 5 ns between source register `reg1` and destination register `reg2`, enter the following Tcl command:

```
set_instance_assignment -name MAX_DELAY 8ns -from reg1 -to reg2
set_instance_assignment -name MIN_DELAY 5ns -from reg1 -to reg2
```

To apply a **Maximum Delay** of 10 ns for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_instance_assignment -name MAX_DELAY 10ns -from clk_src -to clk_dst
```

## Maximum Clock Arrival Skew

The following Tcl command defines the **Maximum Clock Arrival Skew** assignment:

```
set_instance_assignment -name max_clock_arrival_skew <value> -from <clock> -to <node>
```

To apply a **Maximum Clock Arrival Skew** of 1 ns for clock source `clk` to a predefined timegroup called `reg_group`, enter the following Tcl command:

```
set_instance_assignment -name max_clock_arrival_skew 1ns -from clk -to reg_group
```

## Maximum Data Arrival Skew

To create **Maximum Data Arrival Skew** assignments, use the Tcl command `set_instance_assignment -name max_data_arrival`:

```
set_instance_assignment -name max_data_arrival_skew <value> -from <clock> -to <node>
```

To apply a **Maximum Data Arrival Skew** of 1 ns for clock source `clk` to a predefined timegroup of pins called `pin_group`, enter the following Tcl command:

```
set_instance_assignment -name max_data_arrival_skew 1ns -from clk -to pin_group
```

## Multicycle

Use the `set_multicycle_assignment` Tcl command to create **Multicycle** assignments:

```
set_multicycle_assignment [-h | -help] [-long_help] [-setup] [-hold] [-start] [-end]
[-from <from_list>] [-to <to_list>] [-remove] [-disable] [-comment <comment>]
<path_multiplier>
```

To apply a **Multicycle Setup** of 2 and a **Hold Multicycle** of 1 between source register `reg1` and destination register `reg2`, enter the following Tcl commands:

```
set_multicycle_assignment -setup -end -from reg1 -to reg2 2
set_multicycle_assignment -hold -end -from reg1 -to reg2 1
```

To apply a **Source Multicycle Setup** of 2 between source register `reg1` and destination register `reg2`, enter the following Tcl command:

```
set_multicycle_assignment -setup -start -from reg1 -to reg2 1
```

To apply a **multicycle setup** of 2 for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_multicycle_assignment -setup -end -from clk_src -to clk_dst 2
```

## Output Delay Assignment

Use the Tcl command `set_output_delay` to create **Output Delay** assignments:

```
set_output_delay [-h | -help] [-long_help] [-clk_ref <clock>] -to <output_pin> [-min]
[-max] [-clock_fall] [-remove] [-disable] [-comment <comment>] [<value>]
```

To apply an **Output Maximum Delay** of 3 ns to an output pin named `data_out` that is fed to a register clocked by clock source `clk`, enter the following Tcl command:

```
set_output_delay -clk_ref clk -to data_out -max 3ns
```

## Report Timing

Use the `report_timing` Tcl command to generate timing reports:

```
report_timing [-h | -help] [-long_help] [-npaths <number>] [-tsu] [-th] [-tco] [-tpd] \
[-min_tco] [-min_tpd] [-clock_setup] [-clock_hold] [-clock_setup_io] [-clock_hold_io] \
[-clock_setup_core] [-clock_hold_core] [-recovery] [-removal] [-dqs_read_capture] \
[-stdout] [-file <name>] [-append] [-table <name>] [-from <names>] [-to <names>] \
[-clock_filter <names>] [-src_clock_filter <names>] [-longest_paths] [-shortest_paths] \
[-all_failures]
```

The following example generates a list of all clock setup paths for clock source `clk` from registers `src_reg*` to registers `dst_reg*`:

```
report_timing -clock_setup -clock_filter clk -from src_reg* -to dst_reg*
```

## Setup and Hold Relationships

The following Tcl commands create **Setup Relationship** and **Hold Relationship** assignments, respectively:

```
set_instance_assignment -name SETUP_RELATIONSHIP <value> -from <node> -to <node>
set_instance_assignment -name HOLD_RELATIONSHIP <value> -from <node> -to <node>
```

To apply a **Setup Relationship** of 12 ns and a **Hold Relationship** of 2 ns between source register `reg1` and destination registers `reg2`, enter the following Tcl command:

```
set_instance_assignment -name SETUP_RELATIONSHIP 12ns -from reg1 -to reg2
set_instance_assignment -name HOLD_RELATIONSHIP 2ns -from reg1 -to reg2
```

To apply a setup relationship of 10 ns for all paths from source clock `clk_src` to destination clock `clk_dst`, enter the following Tcl command:

```
set_instance_assignment -name SETUP_RELATIONSHIP 10ns -from clk_src -to clk_dst
```

## Assignment Group

Use the `timegroup` Tcl command to create assignment groups:

```
timegroup [-h | -help] [-long_help] [-add_member <name>] [-add_exception <name>] \
[-remove_member <name>] [-remove_exception <name>] [-get_members] [-get_exceptions] \
[-overwrite] [-remove] [-disable] [-comment <comment>] <group_name>
```

The following example creates an assignment group called `reg_bank` with members `dst_reg*`, and excludes register `dst_reg5`.

```
timegroup reg_bank -add_member dst_reg* -add_exception dst_reg5
```

## Virtual Clock

Use the `create_relative_clock` with the `-virtual` switch to create **Virtual Clock** assignments:

```
create_relative_clock [-h | -help] [-long_help] -base_clock <Base clock> \
[-duty_cycle <integer>] [-multiply <integer>] [-divide <integer>] [-offset <offset>] \
[-phase_shift <integer>] [-invert] [-virtual] [-target <name>] [-no_target] \
[-entity <entity>] [-disable] [-comment <comment>] <clock_name>
```

To define a virtual clock derived from the base clock setting `clk_aux` named `brd_sys`, enter the following Tcl command:

```
create_relative_clock -base_clock clk_aux -virtual brd_sys
```

## MAX+PLUS II Timing Analysis Methodology

This section describes the basic static timing analysis and assignments available in the Quartus II software that originated in the MAX+PLUS® II design software.

### $f_{MAX}$ Relationships

Maximum clock frequency is the fastest speed at which the design clock can run without violating internal setup and hold time requirements. The Quartus II software performs static timing analysis on both single- and multiple-clock designs.

Apply clock settings to all clock nodes in a design to ensure that you meet all performance requirements. Refer to [“Clock Settings” on page 8–8](#) for more information.

### Slack

Slack is the margin by which a timing requirement such as  $f_{MAX}$  is met or not met. Positive slack indicates the margin by which a requirement is met. Negative slack indicates the margin by which a requirement is not met. The Quartus II software determines slack using [Equations 35 through 38](#).

- (35) Clock Setup Slack = Longest Register-to-Register Requirement – Longest Register-to-Register Delay
- (36) Register-to-Register Requirement = Setup Relationship + Largest Clock Skew –  $\text{micro } t_{CO}$  of Source Register –  $\text{micro } t_{SU}$  of Destination Register
- (37) Clock Hold Slack = Shortest Register-to-Register Delay – Smallest Register-to-Register Requirement
- (38) Shortest Register-to-Register Requirement = Hold Relationship + Smallest Clock Skew –  $\text{micro } t_{CO}$  of Source Register –  $\text{micro } t_H$  of Destination Register

Figure 8–34 shows a slack calculation diagram.

Figure 8–34. Slack Calculation Diagram

## I/O Timing

This section describes the basic measurements made for I/O timing in the Quartus II software.

### $t_{SU}$ Timing

$t_{SU}$  specifies the length of time data needs to arrive and be stable at an external input pin prior to a clock transition on an associated clock I/O pin. A  $t_{SU}$  requirement describes this relationship for an input register relative to the I/O pins of the FPGA. Figure 8–35 shows a diagram of clock setup time.

**Figure 8–35. Clock Setup Time ( $t_{SU}$ )**

Micro  $t_{SU}$  is the internal setup time of the register. It is a characteristic of the register and is unaffected by the signals feeding the register. Equation 39 calculates the  $t_{SU}$  of data with respect to `clk` for the circuit shown in Figure 8–35.

$$(39) \quad t_{SU} = \text{Longest Data Delay} - \text{Shortest Clock Delay} + \text{micro } t_{SU} \text{ of Input Register}$$

### $t_H$ Timing

$t_H$  specifies the length of time data needs to be held stable on an external input pin after a clock transition on an associated clock I/O pin. A  $t_H$  requirement describes this relationship for an input register relative to the I/O pins of the FPGA. Figure 8–36 shows a diagram of clock hold time.

**Figure 8–36. Clock Hold Time ( $t_H$ )**

Micro  $t_H$  is the internal hold time of the register. Equation 40 calculates the  $t_H$  of data with respect to  $clk$  for the circuit shown in Figure 8–36.

$$(40) \quad t_H = \text{Longest Clock Delay} - \text{Shortest Data Delay} + \text{micro } t_H \text{ of Input Register}$$

### $t_{CO}$ Timing

Clock-to-output delay is the maximum time required to obtain a valid output at an output pin fed by a register, after a clock transition on the input pin that clocks the register. Micro  $t_{CO}$  is the internal clock-to-output delay of the register. Figure 8–37 shows a diagram of clock-to-output delay.

**Figure 8–37. Clock-to-Output Delay ( $t_{CO}$ )**

Equation 41 calculates the  $t_{CO}$  for output pin  $data\_out$  with respect to clock node  $clk$  for the circuit shown in Figure 8–37.

$$(41) \quad t_{CO} = \text{Longest Clock Delay} + \text{micro } t_{CO} \text{ of Output Register}$$

*Minimum  $t_{CO}$  (min  $t_{CO}$ )*

Minimum clock-to-output delay is the minimum time required to obtain a valid output at an output pin fed by a register, after a clock transition on the input pin that clocks the register. Micro  $t_{CO}$  is the internal clock-to-output delay of registers in Altera FPGAs. Unlike the  $t_{CO}$  assignment, the min  $t_{CO}$  assignment looks at the shortest delay paths (Equation 42).

$$(42) \quad \text{min } t_{CO} = \text{Shortest Clock Delay} + \text{Shortest Data Delay} + \text{micro } t_{CO} \text{ of Output Register}$$

 *$t_{PD}$  Timing*

Pin-to-pin delay ( $t_{PD}$ ) is the time required for a signal from an input pin to propagate through combinational logic and appear at an external output pin (Equation 43).

$$(43) \quad t_{PD} = \text{Longest Pin-to-Pin Delay}$$

In the Quartus II software, you can make  $t_{PD}$  assignments between an input pin and an output pin.

*Minimum  $t_{PD}$  (min  $t_{PD}$ )*

The minimum pin-to-pin delay ( $t_{PD}$ ) is the time required for a signal from an input pin to propagate through combinational logic and appear at an external output pin. Unlike the  $t_{PD}$  assignment, the min  $t_{PD}$  assignment applies to the shortest pin-to-pin delay (Equation 44).

$$(44) \quad \text{min } t_{PD} = \text{Shortest Pin-to-Pin Delay}$$

**The Timing Analyzer Tool**

To facilitate the classic static timing analysis flow and constraint, the Quartus II software provides a MAX+PLUS II-style Timing Analyzer Tool available on the Tools menu. The Timing Analyzer Tool provides a simple interface, similar to the Timing Analyzer tool in MAX+PLUS II, that reports register-to-register performance, I/O timing, and custom delay values (Figure 8–38).

**Figure 8–38. Timing Analyzer Tool**

## Conclusion

Evolving design and aggressive process technologies require larger and higher-performance FPGA designs. Increasing design complexity demands enhanced static timing analysis tools that aid designers in verifying design timing requirements. Without advanced static timing analysis tools, you risk circuit failure in complex designs. The Quartus II Classic Timing Analyzer incorporates a set of powerful static timing analysis features critical in enabling system-on-a-programmable-chip (SOPC) designs.

### Introduction

PrimeTime is an industry standard sign-off tool that performs static timing analysis on ASIC designs. The Quartus® II software makes it easy for designers to analyze their Quartus II projects using the PrimeTime software. The Quartus II software exports a netlist, design constraints (in the PrimeTime format), and libraries to the PrimeTime software environment. Figure 9-1 shows the PrimeTime flow diagram.

**Figure 9-1. The PrimeTime Software Flow Diagram**

This chapter contains the following sections:

- “Quartus II Settings for Generating the PrimeTime Software Files” on page 9-2
- “Files Generated for the PrimeTime Software Environment” on page 9-3
- “Running the PrimeTime Software” on page 9-10
- “PrimeTime Timing Reports” on page 9-12
- “Static Timing Analyzer Differences” on page 9-23

## Quartus II Settings for Generating the PrimeTime Software Files

To set the Quartus II software to generate files for the PrimeTime software, perform the following steps:

1. In the Quartus II software, on the Assignments menu, click **EDA Tool Settings**.
2. In the **Category** list, under **EDA Tool Settings**, select **Timing Analysis**.
3. In the **Tool name** drop-down list, select **PrimeTime**, and in the **Format for output netlist** drop-down list, select either **Verilog** or **VHDL**, depending on the HDL language you chose for use with the PrimeTime software (Figure 9–2).

Figure 9–2. Setting the Quartus II Software to Generate the PrimeTime Software Files

When you compile your project after making these settings, the Quartus II software runs the EDA Netlist Writer to create three files for the PrimeTime software. These files are saved in the `<revision_name>/timing/primetime` directory by default, where `<revision_name>` is the name of your Quartus II software revision. If it is not, you have used the wrong variable name.

## Files Generated for the PrimeTime Software Environment

The Quartus II software generates a flattened netlist, a Standard Delay Output File (.sdo), and a Tcl script that prepares the PrimeTime software for timing analysis of the Quartus II project. These files are saved in the `<project_directory>/timing/primetime` directory.

The Quartus II software uses the EDA Netlist Writer to generate PrimeTime files based on either the Quartus II Classic Timing Analyzer or the Quartus II TimeQuest Timing Analyzer static timing analysis results. When you run the EDA Netlist Writer, the PrimeTime SDO files are based on delays generated by the currently selected timing analysis tool in the Quartus II software.

To specify the timing analyzer, on the Assignments menu, click **Settings**. The **Settings** dialog box appears. Under **Category**, click **Timing Analysis Settings**. Select the timing analyzer of your choice.

For more information about specifying the Quartus II timing analyzers, refer to either the *Quartus II Classic Timing Analyzer* or the *Quartus II TimeQuest Timing Analyzer* chapters in volume 3 of the *Quartus II Handbook*. Also, refer to the *Switching to the Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook* to help you decide which timing analyzer is most appropriate for your design.

### The Netlist

Depending on whether **Verilog** or **VHDL** is selected as the **Format for output netlist** option, in the **Tool name** list on the **Timing Analysis** page of the **Settings** dialog box, the netlist is written and saved as either `<project name>.vo` or `<project name>.vho`, respectively. This file contains the flattened netlist representing the entire design.

When the Quartus II TimeQuest Timing Analyzer is selected, only a Verilog PrimeTime netlist is generated.

## The SDO File

The Quartus II software saves the Standard Delay Format Output (.sdo) File as either `<revision_name>_v.sdo` or `<revision_name>_vhd.sdo`, depending on whether you selected **Verilog** or **VHDL** in the **Tool name** list on the **Timing Analysis** page of the **Settings** dialog box.

This file contains the timing information for each timing path between any two nodes in the design.

When the Quartus II Classic Timing Analyzer is enabled, the slow-corner (worst case) timing models are used by default when generating the SDO file. To generate the SDO file using the fast-corner (best case) timing models, perform the following steps:

1. In the Quartus II software, on the Processing menu, point to Start and click **Start Classic Timing Analyzer (Fast Timing Model)**.
2. After the fast-corner timing analysis is complete, on the Processing menu, point to Start and click **Start EDA Netlist Writer** to create a `<revision_name>_v_fast.sdo` or `<revision_name>_vhd_fast.sdo` file, which contains the best-case delay values for each timing path.

If you are running a best-case timing analysis, the Quartus II software generates a Tcl script similar to the following:  
`<revision_name>_pt_v_fast.tcl`.

When TimeQuest is run with the fast-corner netlist or when the **Optimize fast-corner timing** check box is selected in the **Fitter Settings** dialog box, the fast-corner SDC file is generated.

After the EDA Netlist Writer has finished, two SDO files are created: `<revision_name>_v.sdo` (slow-corner) or `<revision_name>_v_fast.sdo` (fast-corner).

### *Generating Multiple Operating Conditions with TimeQuest*

Different operating conditions can be specified to the EDA Netlist Writer for PrimeTime analysis. The different operating conditions are reflected in the .sdo file generated by the EDA Netlist Writer.

Table 9–1 shows the available operating conditions that can be set for a few of Altera's device families.

<b>Table 9–1. Available Operating Condition Combinations</b>	
<b>Device Family</b>	<b>Available Conditions (Model, Voltage, Temperature)</b>
Stratix III	(slow, 1100 mV, 85° C), (slow, 1100 mV, 0° C), (fast, 1100 mV, 0° C)
Cyclone III	(slow, 1200 mV, 85° C), (slow, 1200 mV, 0° C), (fast, 1200 mV, 0° C)
Stratix II	(slow, N/A, N/A), (fast, N/A, N/A)
Cyclone II	(slow, N/A, N/A), (fast, N/A, N/A)

 From the TimeQuest Console pane, use the command `get_available_operating_conditions` to obtain a list of available operating conditions for the target device.

The following steps show how to generate the `.sdo` files for the three different operating conditions for a Stratix III design. Each command must be entered at the command prompt.

 The `-tq2pt` option for `quartus_sta` is required only if the project doesn't specify that PrimeTime tool will be used as the timing analysis tool.

1. Generate the first slow corner model at the operating conditions: slow, 1100 mV, and 85° C.

```
quartus_sta --model=slow --voltage=1100 --
temperature=85 <project name>
```

2. Generate the fast corner model at the operating conditions: fast, 1100 mV, and 0° C.

```
quartus_sta --model=fast --voltage=1100 --
temperature=0 --tq2pt <project name>
```

3. Generate the PrimeTime output files for the corners specified above. The output files will be generated in the `primetime_two_corner_files` directory.

```
quartus_eda --timing_analysis --tool=primetime
--format=verilog --
output_directory=primetime_two_corner_files --
write_settings_files=off <project name>
```

4. Generate the second slow corner model at the operating conditions: slow, 1100 mV, and 0° C.

```
quartus_sta --model=slow --voltage=1100 --
temperature=0 --tq2pt <project name>
```

5. Generate the PrimeTime output files for the second slow corner. The output files will be generated in the `primetime_one_slow_corner_files` directory.

```
quartus_eda --timing_analysis --tool=primetime --
format=verilog --
output_directory=primetime_one_slow_corner_files -
-write_settings_files=off $revision
```

To summarize, the previous steps generate the following files for the three operating conditions:

- First slow corner (slow, 1100 mV, 85° C) :  
VO File—`primetime_two_corner_files/<project name>.vo`  
SDO File—`primetime_two_corner_files/<project name>_v.sdo`
- Fast corner (fast, 1100 mV, 0° C) :  
VO File—`primetime_two_corner_files/<project name>.vo`  
SDO File—`primetime_two_corner_files/<project name>_v_fast.sdo`
- Second slow corner (slow, 1100 mV, 0° C) :  
VO File—`primetime_one_slow_corner_files/<project name>.vo`  
SDO File—`primetime_one_slow_corner_files/<project name>_v.sdo`

The directory `primetime_one_slow_corner_files` may also have files for fast corner. These files can be ignored since they were already generated in the `primetime_two_corner_files` directory.

## The Tcl Script

The Tcl script generated by the Quartus II software contains information required by the PrimeTime software to analyze the timing and set up your post-fit design. This script specifies the search path and the names of the PrimeTime database library files provided with the Quartus II software. The `search_path` and `link_path` variables are defined at the beginning of the Tcl file. The `link_path` variable is a space-delimited list that contains the names of all database files used by the PrimeTime software.

Depending on whether you selected **Verilog** or **VHDL** in the **Format for output netlist** list on the **Timing Analysis** page of the **Settings** dialog box, when the Quartus II Classic Timing Analyzer is enabled, the EDA Netlist Writer generates and saves the script as either `<revision_name>_pt_v.tcl` or `<revision_name>_pt_vhd.tcl`.

To access the **EDA Settings** dialog box, on the Assignments menu, click **EDA Tool Settings**, then expand **EDA Tool Settings** under the Category list. In the dialog box, you can specify VHDL or Verilog for the format for the output netlist.

The script also directs the PrimeTime software to use the `<device family>_all_pt.v` or `<device family>_all_pt.vhd` file, which contains the Verilog or VHDL description of library cells for the targeted device family.

**Example 9-1** shows the `search_path` and `link_path` variables defined in the Tcl script:

---

### Example 9-1. Sample PrimeTime Setup Script

```
set quartus_root "altera/quartus/"
set search_path [list . [format "%s%s" $quartus_root "eda/synopsys/primetime/lib"] ]

set link_path [list * stratixii_lcell_comb_lib.db stratixii_lcell_ff_lib.db
stratixii_asynch_io_lib.db stratixii_io_register_lib.db stratixii_termination_lib.db
bb2_lib.db stratixii_ram_internal_lib.db stratixii_memory_register_lib.db
stratixii_memory_addr_register_lib.db stratixii_mac_out_internal_lib.db
stratixii_mac_mult_internal_lib.db stratixii_mac_register_lib.db
stratixii_lvds_receiver_lib.db stratixii_lvds_transmitter_lib.db
stratixii_asmiblock_lib.db stratixii_crcblock_lib.db stratixii_jtag_lib.db
stratixii_rublock_lib.db stratixii_pll_lib.db stratixii_dll_lib.db alt_vt1.db]

read_vhdl -vhdl_compiler stratixii_all_pt.vhd
```

---

The EDA Netlist Writer converts any Quartus II Classic Timing Analyzer timing assignments to the PrimeTime software constraints and exceptions when it generates the PrimeTime files. The converted constraints are saved to the Tcl script. The Tcl script also includes a

PrimeTime software command that reads the Standard Delay Format Output (.sdo) file generated by the Quartus II software. You can place additional commands in the Tcl script to analyze or report on timing paths.

Table 9–2 shows some examples of timing assignments converted by the Quartus II software for the PrimeTime software. For example, the `set_input_delay -max` command sets the input delay on an input pin.

<b>Table 9–2. Equivalent Quartus II and PrimeTime Software Constraints</b>	
<b>Quartus II Equivalent</b>	<b>PrimeTime Constraint</b>
Clock defined on input pin, clock of 10 ns period and 50% duty cycle	<code>create_clock -period 10.000 -waveform {0 5.000} \ [get_ports clk] -name clk</code>
Input maximum delay of 1 ns on input pin, <b>din</b>	<code>set_input_delay -max -add_delay 1.000 -clock \ [get_clocks clk] [get_ports din]</code>
Input minimum delay of 1 ns on input pin, <b>din</b>	<code>set_input_delay -min -add_delay 1.000 -clock \ [get_clocks clk] [get_ports din]</code>
Output maximum delay of 3 ns on output pin, <b>out</b>	<code>set_output_delay -max -add_delay 3.000 -clock \ [get_clocks clk] [get_ports out]</code>

When the Quartus II TimeQuest Timing Analyzer is turned on, the EDA Netlist Writer generates and saves the script as `<revision_name>.pt.tcl`.

The EDA Netlist Writer converts all Quartus II TimeQuest Timing Analyzer SDC constraints and exceptions into compatible PrimeTime software constraints and exceptions when it generates the PrimeTime files. The constraints and exceptions are saved to the `<revision_name>.constraints.sdc` file.

*Generated File Summary*

The files that are generated by the EDA Netlist Writer for the PrimeTime software depend on the Quartus II timing analysis tool you selected.

Table 9–3 shows the files that are generated for the PrimeTime software when the Quartus II Classic Timing Analyzer is selected.

<b>File</b>	<b>Description</b>
<revision_name>.vho   <revision_name>.vo	The PrimeTime software output netlist. Either a VHDL Output File or a Verilog Output file is generated, depending on the output netlist language set.
<revision_name>_vhd.sdo   <revision_name>_v.sdo	The PrimeTime software standard delay file. Either a VHDL Standard Delay Output file or a Verilog Standard Delay Output file is generated, depending on the output netlist language set.
<revision_name>_pt_vhd.tcl   <revision_name>_pt_v.tcl	PrimeTime setup and constraint script. Either a VHDL Tcl script or a Verilog Tcl script is generated, depending on the output netlist language set.

Table 9–4 shows the files that are generated for the PrimeTime software when the Quartus II TimeQuest Timing Analyzer is selected. The EDA Netlist Writer supports the output netlist format only when the TimeQuest Timing Analyzer is enabled.

<b>File</b>	<b>Description</b>
<revision_name>.vo	The PrimeTime software output netlist. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<revision_name>_v.sdo   <revision_name>_v_fast.sdo	The PrimeTime software standard delay file. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<revision_name>.pt.tcl	PrimeTime setup and constraint script. When the Quartus II TimeQuest Timing Analyzer is enabled, only PrimeTime (Verilog) is supported.
<revision_name>.collections.sdc	Contains the mapping from the Quartus II TimeQuest Timing Analyzer netlist to the PrimeTime netlist.
<revision_name>.constraints.sdc	Contains the converted Quartus II TimeQuest Timing Analyzer constraints for the PrimeTime software.

## Running the PrimeTime Software

The PrimeTime software runs only on UNIX operating systems. If the Quartus II output files for the PrimeTime software were generated by running the Quartus II software on a PC/Windows-based system, follow these steps to run the PrimeTime software using Quartus II output files:

1. Install the PrimeTime libraries on a UNIX system by installing Quartus II software on UNIX.

The PrimeTime libraries are located in the *<Quartus II installation directory>/eda/synopsys/primetime/lib* directory.

2. Copy the Quartus II output files to the appropriate UNIX directory. You may need to run a PC to UNIX program, such as `dos2unix`, to remove any control characters.
3. Modify the Quartus II path in Tcl scripts to point to the PrimeTime libraries, as described in Step 1. In [Example 9-1](#), the first line is:

```
set quartus_root "altera/quartus/" set search_path [list . [format "%s%s" $quartus_root "eda/synopsys/primetime/lib" ]
```

This is the Tcl script that should be modified.

### Analyzing Quartus II Projects

The PrimeTime software is controlled with Tcl scripts and can be run through `pt_shell`. You can run the *<revision\_name>\_pt\_v.tcl* script file. For example, type the following at a UNIX system command prompt:

```
pt_shell -f <revision_name>_pt_v.tcl ←
```

When the Quartus II TimeQuest Timing Analyzer is selected, type the following at a UNIX system command prompt:

```
pt_shell -f <revision_name>.pt.tcl ←
```

After all Tcl commands in the script are interpreted, the PrimeTime software returns control to the `pt_shell` prompt, which allows you to use other commands.

## Other pt\_shell Commands

You can run additional `pt_shell` commands at the `pt_shell` prompt, including the `man` program. For example, to read documentation about the `report_timing` command, type the following at the `pt_shell` prompt:

```
man report_timing ↵
```

You can list all commands available in `pt_shell` by typing the following at the `pt_shell` prompt:

```
help ↵
```

Type `quit` ↵ at the `pt_shell` prompt to close `pt_shell`.

You can also run `pt_shell` without a script file by typing `pt_shell` ↵ at the UNIX command line prompt.

## PrimeTime Timing Reports

### Sample of the PrimeTime Software Timing Report

After running the script, the PrimeTime software generates a timing report. If the timing constraints are not met, `Violated` is displayed at the end of the timing report. The timing report also gives the negative slack.

The PrimeTime software report is similar to the sample shown in [Example 9-2](#). The starting point in this report is a register clocked by clock signal, `clock`, the endpoint is another register, `inst3-I.lereg`.

---

#### **Example 9-2. Hold Path Report in PrimeTime**

```

Startpoint: inst2~I.lereg
  (rising edge-triggered flip-flop clocked by clock)
Endpoint: inst3~I.lereg
  (rising edge-triggered flip-flop clocked by clock)
Path Group: clock
Path Type: min

## Comparing Timing Reports from the Quartus II Classic Timing Analyzer and the PrimeTime Software

Both the Quartus II Classic Timing Analyzer and the Quartus II TimeQuest Timing Analyzer generate a static timing analysis report for every successful design compilation. The timing report lists all of the analyzed timing paths in your design that were analyzed, and indicates whether these paths have met or violated their timing requirements. Violations are reported only if timing constraints were specified.

The Quartus II TimeQuest Timing Analyzer uses an equivalent set of equations as PrimeTime when reporting the static timing analysis result for a design. However, the Quartus II Classic Timing Analyzer uses slightly different reporting equations when reporting the static timing analysis results for a design. This section describes these differences between the Quartus II Classic Timing Analyzer and the PrimeTime software.

The timing report generated by the Quartus II Classic Timing Analyzer differs from the report generated by the PrimeTime software. Both tools provide the same data but present in different formats. The following sections show how the PrimeTime software reports the following slack values differently from the Quartus II Classic Timing Analyzer report:

- [“Clock Setup Relationship and Slack” on page 9–13](#)
- [“Clock Hold Relationship and Slack” on page 9–17](#)
- [“Input Delay and Output Delay Relationships and Slack” on page 9–21](#)

### *Clock Setup Relationship and Slack*

The Quartus II Classic Timing Analyzer performs a setup check that ensures that the data launched by source registers is latched correctly at the destination registers. The Quartus II Classic Timing Analyzer does this by determining the data arrival time and clock arrival time at the destination registers, and compares this data with the setup time delay of the destination register. [Equation 1](#) expresses the inequality that is used for a setup check. The data arrival time includes the longest path from the clock to the source register, the clock-to-out micro delay of the source register, and the longest path from the source register to the destination register. The clock arrival time is the shortest delay from the clock to the destination register.

(1)  $\text{Clock Arrival} - \text{Data Arrival} \geq t_{\text{su}}$

Slack is the margin by which a timing requirement is met or not met. Positive slack indicates the margin by which a requirement is met. Negative slack indicates the margin by which a requirement was not met. The Quartus II Classic Timing Analyzer determines the clock setup slack, with Equation 2:

$$(2) \text{ Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

The longest register-to-register delay in the previous equation is equal to the register-to-register data delay.

$$(3) \text{ Largest Register-to-Register Requirement} = \text{Setup Relationship between Source and Destination} + \text{Largest Clock Skew} - \text{Micro } t_{co} \text{ of Destination Register} - \text{Micro } t_{su} \text{ of Destination Register}$$

$$\text{Setup Relationship between Source and Destination} = \text{Latch Edge} - \text{Launch Edge}$$

$$\text{Clock Skew} = \text{Shortest Clock Path to Destination} - \text{Longest Clock Path to Source}$$

For a simple three-register design, refer to Figure 9-3.

**Figure 9-3. Simple Three-Register Design**

The Quartus II Classic Timing Analyzer generates a report for the design, as shown in Figure 9–4.

Figure 9–4. Timing Analyzer Report from Figure 9–3

	Slack	Actual fmax (period)	From	To	From Clock	To Clock	Required Setup Relationship	Required Longest P2P Time	Actual Longest P2P Time
1	4.237 ns	265.75 MHz ( period = 3.763 ns )	inst2	inst3	clock	clock	8.000 ns	7.650 ns	3.413 ns
2	4.741 ns	306.84 MHz ( period = 3.259 ns )	inst	inst2	clock	clock	8.000 ns	7.980 ns	3.239 ns

Equation 1, 2, and 3 are similar to those found in other static timing analysis tools, such as the PrimeTime software. Equation 4, 5, 6, and 7, used by the PrimeTime software, are essentially the same as those used by the Quartus II Classic Timing Analyzer, but they are rearranged.

- (4)  $\text{Slack} = \text{Data Required} - \text{Data Arrival}$
- (5)  $\text{Clock Arrival} = \text{Latch Edge} + \text{Shortest Clock Path to Destination}$
- (6)  $\text{Data Required} = \text{Clock Arrival} - \text{Micro } t_{su}$
- (7)  $\text{Data Arrival} = \text{Launch Edge} + \text{Longest Clock Path to Source} + \text{Micro } t_{co} + \text{Longest Data Delay}$

The longest data delay in the previous equation is equal to register-to-register data delay.

Figure 9–5 shows a clock setup check in the Quartus II software.

**Figure 9–5. Clock Setup Check Reporting with the Quartus II Classic Timing Analyzer**

The following results are obtained by extracting the numbers from the Quartus II Classic Timing Analyzer report and applying them to the clock setup slack equations from the Quartus II Classic Timing Analyzer:

$$(8) \quad \text{Setup Relationship between Source and Destination} = \text{Latch Edge} - \text{Launch Edge} - \text{Clock Setup Uncertainty}$$

$$8.0 - 0.0 - 0.0 = 8.0\text{ns}$$

$$\text{Clock Skew} = \text{Shortest Clock Path to Destination} - \text{Longest Clock Path to Source}$$

$$3.002 - 3.166 = -0.164\text{ns}$$

$$\begin{aligned} \text{Largest Register-to-Register Requirement} &= \\ \text{Setup Relationship between Source \& Destination} &+ \text{Largest Clock Skew} \\ - \text{Micro } t_{\text{co}} \text{ of Source Register} &- \text{Micro } t_{\text{su}} \text{ of Destination Register} \end{aligned}$$

$$8 + (-0.164) - 0.176 - 0.010 = 7.650\text{ns}$$

$$\text{Clock Setup Slack} = \text{Largest Register-to-Register Requirement} - \text{Longest Register-to-Register Delay}$$

$$7.650 - 3.413 = 4.237\text{ns}$$

For the same register-to-register path, the PrimeTime software generates a clock setup report as shown in [Example 9-3](#):

---

**Example 9-3. Setup Path Report in PrimeTime**

### *Clock Hold Relationship and Slack*

The Quartus II Classic Timing Analyzer performs a hold time check along every register-to-register path in the design to ensure that no hold time violations have occurred. The hold time check verifies that data from the source register does not reach the destination until after the hold time of the destination register. The condition used for a hold check is shown in [Equation 9](#):

$$(9) \quad \text{Data Arrival} - \text{Clock Arrival} \geq t_H$$

The Quartus II Classic Timing Analyzer determines the clock hold slack with [Equation 10](#), [11](#), [12](#), and [13](#):

$$(10) \quad \text{Clock Hold Slack} = \text{Shortest Register-to-Register Delay} - \text{Smallest Register-to-Register Requirement}$$

- (11)  $\text{Smallest Register-to-Register Requirement} = \text{Hold Relationship between Source \& Destination} + \text{Smallest Clock Skew} - \text{Micro } t_{su} \text{ of Source} + \text{Micro } t_H \text{ of Destination}$
- (12)  $\text{Hold Relationship between Source \& Destination} = \text{Latch Edge} - \text{Launch Edge}$
- (13)  $\text{Smallest Clock Skew} = \text{Longest Clock Path from Clock to Destination Register} - \text{Shortest Clock Path from Clock to Source Register}$

Figure 9–6 shows a simple three-register design.

Figure 9–6. A Simple Three-Register Design

The Quartus II Classic Timing Analyzer generates a report as shown in Figure 9–7.

Figure 9–7. Timing Analyzer Report Generated from the Three Register Design

The previous equations are similar to those found in the Quartus II software. The following equations are the same equations that are used by the PrimeTime software, but they are rearranged.

- (14) Slack = Data Required – Data Arrival
- (15) Clock Arrival = Latch Edge + Longest Clock Path to Destination
- (16) Data Required = Clock Arrival – Micro  $t_H$
- (17) Data Arrival = Launch Edge + Longest Clock Path to Source + Micro  $t_{CO}$  + Shortest Data Delay

The shortest register-to-register delay in the previous equation is equal to register-to-register data delay.

Figure 9–8 shows a clock setup check with the Quartus II Classic Timing Analyzer.

**Figure 9–8. Clock Hold Check Reporting with the Quartus II Classic Timing Analyzer**

The following results are obtained by extracting the numbers from the Timing Analysis report and applying the clock setup slack equations from the Quartus II Classic Timing Analyzer.

- (18) Clock Hold Slack = Shortest Register-to-Register Delay – Smallest Register-to-Register Requirement
- $$3.413 - (-0.240) = 3.653\text{ns}$$

$$\begin{aligned} \text{Smallest Register-to-Register Requirement} &= \text{Hold Relationship between Source \& Destination} + \\ &\text{Smallest Clock Skew} - \text{Micro } t_{CO} \text{ of Source} + \text{Micro } t_H \text{ of Destination} \\ &0 + (-0.164) - 0.176 + 0.100 = -0.240\text{ns} \end{aligned}$$

Hold Relationship between Source & Destination = Latch – Launch  
 0.0 – 0.0ns

Smallest Clock Skew = Longest Clock Path from Clock to Destination Register –  
 Shortest Clock Path from Clock to Source Register  
 3.002 – 3.166 = –0.164ns

For the same register-to-register path, the PrimeTime software generates the report shown in [Example 9–4](#):

---

**Example 9–4. Hold Path Report in PrimeTime**

```

Startpoint: inst2~I.lereg

data arrival time-6.755
-----
slack (MET)3.653
    
```

---

Both sets of hold slack equations can be used to determine the hold slack value of any path.

### Input Delay and Output Delay Relationships and Slack

Input delay and output delay reports generated by the Quartus II Classic Timing Analyzer are similar to the clock setup and clock hold relationship reports. Figure 9–9 shows the input delay and output delay report for the design shown in Figure 9–6 on page 9–18.

**Figure 9–9. Input and Output Delay Reporting with the Quartus II Classic Timing Analyzer**

Figure 9–9 shows a screenshot of the Quartus II Classic Timing Analyzer. The window title is "Compilation Report - Clock Setup (I/O paths): 'clock'". The left sidebar shows a tree view with "Timing Analyzer" expanded to "Clock Setup: 'clock'". The main area displays a table titled "Clock Setup (I/O paths): 'clock'".

	Slack	Actual fmax (period)	From	To	From Clock	To Clock	Required Setup Relationship	Required Longest P2P Time	Actual Longest P2P Time
1	0.175 ns	127.80 MHz ( period = 7.825 ns )	inst3	data_out	clock	clock	8.000 ns	3.572 ns	3.397 ns
2	5.380 ns	381.68 MHz ( period = 2.620 ns )	data_in	inst	clock	clock	8.000 ns	8.490 ns	3.110 ns

Figure 9–10 shows the fully expanded view for the output delay path.

**Figure 9–10. Output Delay Path Reporting with the Quartus II Classic Timing Analyzer**

For the same output delay path, the PrimeTime software generates a report similar to [Example 9-5](#):

---

**Example 9-5. Setup Path Report in PrimeTime**

```

Startpoint: inst3~I.lereg

```

---

To generate a list of the 100 worst paths and place this data into a file called **file.timing**, type the following command at the `pt_shell` prompt:

```
report_timing -nworst 100 > file.timing ◀
```

Timing paths in the PrimeTime software are listed in the order of most-negative-slack to most-positive-slack. The PrimeTime software does not categorize failing paths by default. Timing setup ( $t_{SU}$ ) and timing hold ( $t_H$ ) times are not listed separately. In the PrimeTime software, each path is shown with a start and end point; for example, if it is a

register-to-register or input-to-register type of path. If you only use the `report_timing` part of the command without adding a `-delay` option, only the `setup-time-related` timing paths are reported.

The following command is used to create a minimum timing report or a list of hold-time-related violations:

```
report_timing -delay_type min ←
```

Ensure that the correct SDO file, either minimum or maximum delays, is loaded before running this command.

## Static Timing Analyzer Differences

Under certain design conditions, several static timing analysis differences can exist between the Classic Timing Analyzer and the TimeQuest Timing Analyzer, and the PrimeTime software. The following sections explain the differences between the two static timing analysis engines and the PrimeTime software.

### The Quartus II Classic Timing Analyzer and the PrimeTime Software

The following section describes the differences between the Quartus II Classic Timing Analyzer and the PrimeTime software.

#### *Rise/Fall Support*

The Quartus II Classic Timing Analyzer does not support rise/fall analysis. However, rise/fall support is available in PrimeTime.

#### *Minimum and Maximum Delays*

TimeQuest calculates minimum and maximum delays for all device components with the exception of clock routing. PrimeTime does not model these delays. This can result in different slacks for a given path on average by 2 - 3%.

#### *Recovery/Removal Analysis*

TimeQuest performs a more pessimistic recovery/removal analysis for asynchronous path than PrimeTime. This can result in different delays reported between the two tools.

### Encrypted Intellectual Property Blocks

The Quartus II software has the capability to decrypt all intellectual property (IP) blocks designed for Altera® devices that have been encrypted by their vendors. The decryption process allows the Quartus II software to perform a full compilation of the design that contains an encrypted IP block. This also allows the Quartus II Classic Timing Analyzer to perform a complete static timing analysis on the design. However, when the PrimeTime software is designated as the static timing analysis tool, the Quartus II EDA Netlist Writer does not generate either a VHDL Output File (.vho) or Verilog Output File (.vo) netlist file for designs that contain encrypted IP blocks for which the license does not permit generation of output netlists for third-party tools.

### Registered Clock Signals

Registered clock signals are clock signals that pass through a register before reaching the clock port of a sequential element. Figure 9–11 shows an example of a registered clock signal.

**Figure 9–11. Registered Clock Signal**

If no clock setting is applied to the register on the clock path (shown as register `reg_1` in Figure 9–11), the Quartus II Classic Timing Analyzer treats the register in the clock path as a buffer. The delay of the buffer is equal to the CELL delay of the register plus the  $t_{CO}$  of the register. The PrimeTime software does not treat the register as a buffer.

For more information about creating clock settings, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

### Multiple Source and Destination Register Pairs

In any design, multiple paths may exist from a source register to a destination register. Each path from the source register to the destination register may have a different delay value due to the different routes taken. For example, [Figure 9–12](#) shows a sample design that contains multiple path pairs between the source register and destination register.

**Figure 9–12. Multiple Source and Destination Pairs**

The Quartus II Classic Timing Analyzer analyzes all source and destination pairs, but reports only the source and destination register pair with the worst slack. For example, if the Path 2 pair delay is greater than the Path 1 pair delay in [Figure 9–12](#), the Quartus II Classic Timing Analyzer reports the slack value of the Path 2 pair and not the Path 1 pair. The PrimeTime software reports all possible source and destination register pairs.

### Latches

By default, the Quartus II software implements all latches as combinational loops. The Quartus II Classic Timing Analyzer can analyze such latches by treating them as registers with inverted clocks or analyze latches as a combinational loop modeled as a combinational delay.

For more information about latch analysis, refer to the *Quartus II TimeQuest Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The PrimeTime software always analyzes these latches as combinational loops, as defined in the netlist file.

### LVDS I/O

When it analyzes the dedicated LVDS transceivers in your design, the Quartus II Classic Timing Analyzer generates the Receiver Skew Margin (RSKM) report and a Channel-to-Channel Skew (TCCS) report. The PrimeTime software does not generate these reports.

### *Clock Latency*

When a single clock signal feeds both the source and destination registers of a register-to-register path, and either an Early Clock Latency or a Late Clock Latency assignment has been applied to the clock signal, the Quartus II Classic Timing Analyzer does not factor in the clock latency values when it calculates the clock skew between the two registers. The Quartus II Classic Timing Analyzer factors in the clock latency values when the clock signal to the source and destination registers of a register-to-register path are different. The PrimeTime software applies the clock latency values when a single clock signal or different clock signals feeds the source and destination registers of a register-to-register path.

### *Input and Output Delay Assignments*

When a purely combinational (non-registered) path exists between an input pin and output pin of the Altera FPGA and both pins have been constrained with an input delay and an output delay assignment applied, respectively, the Quartus II Classic Timing Analyzer does not perform a clock setup or clock hold analysis. The PrimeTime software analyzes these paths.

### *Generated Clocks Derived from Generated Clocks*

The Quartus II Classic Timing Analyzer does not support a generated clock derived from a generated clock. This situation might occur if a generated clock feeds the input clock pin of a PLL. The output clock of the PLL is a generated clock.

## **The Quartus II TimeQuest Timing Analyzer and the PrimeTime Software**

The following sections describe the static timing analysis differences between the Quartus II TimeQuest Timing Analyzer and the PrimeTime software.

### *Encrypted Intellectual Property Blocks*

The Quartus II software has the capability to decrypt all IP blocks, designed for Altera devices that have been encrypted by their vendors. The decryption process allows the Quartus II software to perform a full compilation on the design containing an encrypted IP block. This also allows the Quartus II TimeQuest Timing Analyzer to perform a complete static timing analysis on the design. However, when the PrimeTime software is designated as the static timing analysis tool, the Quartus II

EDA Netlist Writer does not generate `.vho` or `.vo` netlist files for designs that contain encrypted IP blocks whose license does not permit generation of output netlists for other tools.

### *Latches*

By default, the Quartus II software implements all latches as combinational loops. The Quartus II TimeQuest Timing Analyzer can analyze such latches by treating them as registers with inverted clocks. The Quartus II TimeQuest Timing Analyzer analyzes latches as a combinational loop modeled as a combinational delay.

For more information about latch analysis, refer to the *Quartus II Classic Timing Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The PrimeTime software always analyzes these latches as combinational loops, as defined in the netlist file.

### *LVDS I/O*

When it analyzes the dedicated LVDS transceivers in your design, the Quartus II TimeQuest Timing Analyzer generates a Receiver Skew Margin (RSKM) report and a Channel-to-Channel Skew (TCCS) report. The PrimeTime software does not generate these reports.

### *The Quartus II TimeQuest Timing Analyzer SDC File and PrimeTime Compatibility*

Because of differences between node naming conventions with the netlist generated by the EDA Netlist Writer and the internal netlist used by the Quartus II software, SDC files generated for the Quartus II software or the Quartus II TimeQuest Timing Analyzer are not compatible with the PrimeTime software.

Run the EDA Netlist Writer to generate a compatible SDC file from the TimeQuest SDC file for the PrimeTime software. After the files have been generated, `<revision_name>.collections.sdc` and `<revision_name>.constraints.sdc`, both files can be read in by the PrimeTime software for compatibility of constraints between the Quartus II TimeQuest Timing Analyzer and the PrimeTime software.

### *Clock and Data Paths*

If a timing path acts both as a clock path (a path that connects to a clock pin with a clock associated to it), and a data path (a path that feeds into the data in port of a register), the Quartus II TimeQuest Timing Analyzer will report the data paths, whereas PrimeTime will not.

### *Inverting and Non-Inverting Propagation*

TimeQuest always propagates non-inverting sense for clocks through non-unate paths in the clock network.

PrimeTime's default behavior is to propagate both inverting and non-inverting senses through a non-unate path in the clock network.

### *Multiple Rise/Fall Numbers For a Timing Arc*

For a given timing path with a corresponding set of pins/ports that make up the path (including source and destination pair), if the individual components of that path have different rise/fall delays, there can potentially be many timing paths with different delays using the same set of pins. If this occurs, TimeQuest reports only one timing path for the set of pins that make up the path.

### *Virtual Generated Clocks*

PrimeTime does not support generated clocks that are virtual. To maintain compatibility between TimeQuest and PrimeTime, all generated clocks should have an explicit target specified.

### *Generated Clocks Derived from Generated Clocks*

The Quartus II Classic Timing Analyzer does not support the creation of a generated clock derived from a generated clock. This situation might occur if a generated clock feeds the input clock pin of another generated clock. The output clock of the PLL is a generated clock.

## **Conclusion**

The Quartus II software can export a netlist, constraints, and timing information for use with the PrimeTime software. The PrimeTime software can use data from either best-case or worst-case Quartus II timing models to measure timing. The PrimeTime software is controlled using a Tcl script generated by the Quartus II software that you can customize to direct the PrimeTime software to produce violation and slack reports.

## Document Revision History

Table 9–5 shows the revision history for this chapter.

<b>Date and Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 9–29.	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>● Added Generating Multiple Operating Conditions with TimeQuest</li> <li>● Added Rise/Fall Support</li> <li>● Added Minimum and Maximum Delays</li> <li>● Added Recovery/Removal Analysis</li> <li>● Added Generated Clocks Derived from Generated Clocks</li> <li>● Added Multiple Rise/Fall Numbers for a Timing Analyzer SDC</li> <li>● Virtual Generated Clocks</li> <li>● Added Referenced Documents</li> </ul>	Updates added to the Static Timing Analyzer Differences section of this chapter.
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only. No other changes made to chapter.	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>● Noted the differences between the different timing analyzers</li> <li>● Explained how to select between the timing analyzers</li> <li>● Introduced the TimeQuest flow with PrimeTime</li> </ul>	Introduction of the TimeQuest Timing Analyzer updated in this chapter.
May 2006 v6.0.0	Chapter title changed to <i>Synopsys PrimeTime Support</i> . Minor updates for the Quartus II software version 6.0.0.	—
October 2005 v5.1.0	Updated for the Quartus II software version 5.1.	—
August 2005 v5.0.1	Minor text updates.	—
May 2005 v5.0.0	New functionality for Quartus II software 5.0.0	—
December 2004 v2.0	<ul style="list-style-type: none"> <li>● Chapter 6 Synopsys PrimeTime moved to section III Volume 1.</li> <li>● New functionality for Quartus II software 4.2.</li> </ul>	—

---

As FPGA designs grow larger and processes continue to shrink, power becomes an ever-increasing concern. When designing a printed circuit board, the power consumed by a device needs to be accurately estimated to develop an appropriate power budget, and to design the power supplies, voltage regulators, heat sink, and cooling system.

The Quartus® II software allows you to estimate the power consumed by your current design during timing simulation. The power consumption of your design can be calculated using the Microsoft Excel-based power calculator, or the Simulation-Based Power Estimation features in the Quartus II software. This section explains how to use both.

This section includes the following chapter:

- [Chapter 10, PowerPlay Power Analysis](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

### Introduction

As designs grow larger and process technology continues to shrink, power becomes an increasingly important design consideration. When designing a printed circuit board (PCB), the power consumed by a device needs to be accurately estimated to develop an appropriate power budget and to design the power supplies, voltage regulators, heat sink, and cooling system. The PowerPlay power analysis tools, made available by Altera®, provide improved power consumption accuracy and the ability to estimate power consumption from early design concept through design implementation, as shown in [Figure 10–1](#).

**Figure 10–1. PowerPlay Power Analysis**

Depending where you are in your design cycle and the accuracy of the estimation required, you can either use the PowerPlay Early Power Estimator spreadsheet or the PowerPlay Power Analyzer Tool in the Quartus® II software. You can use the PowerPlay Early Power Estimator spreadsheet during the board design and layout phase to obtain a power estimate and then design for proper power management. The PowerPlay Power Analyzer Tool is used to obtain an accurate estimation of power after the design is complete, ensuring that thermal and supply budgets are not violated.

You can estimate power consumption for Arria™ GX, Stratix® series devices, Cyclone® series devices, HardCopy® II, and MAX® II devices with the Microsoft Excel-based PowerPlay Early Power Estimator spreadsheet or the PowerPlay Power Analyzer Tool.

For more information about acquiring the PowerPlay Power Estimator spreadsheet for Arria GX, Stratix series devices, Cyclone series, HardCopy II, and MAX II devices and its use, refer to [www.altera.com/support/devices/estimator/pow-powerplay.html](http://www.altera.com/support/devices/estimator/pow-powerplay.html).

This chapter discusses the following topics:

- “Quartus II Early Power Estimator File”
- “Types of Power Analyses” on page 10–6
- “Factors Affecting Power Consumption” on page 10–6
- “Using the PowerPlay Power Analyzer” on page 10–23

## Quartus II Early Power Estimator File

When entering data into the Early Power Estimator spreadsheet, you must enter the device resources, operating frequency, toggle rates, and other parameters. This requires familiarity with the design. If you do not have an existing design, you must estimate the number of device resources used in your design and enter it manually.

If you already have an existing design or a partially completed design, the power estimator file that is generated by the Quartus II software can aid in completing the PowerPlay Early Power Estimator spreadsheet.

To generate the power estimation file, you must first compile your design in the Quartus II software. After compilation is complete, on the Project menu, click **Generate PowerPlay Early Power Estimator File** (Figure 10–2). This command instructs the Quartus II software to write out a power estimator Comma-Separated Value (.csv) file (or a text [.txt] file for older device families).

**Figure 10–2. Generate PowerPlay Early Power Estimator File Option**

After the Quartus II software successfully generates the power estimator file, a message appears (Figure 10–3).

**Figure 10–3. Generate PowerPlay Early Power Estimator File Message**

The power estimator file is named `<name of Quartus II project>_early_pwr.csv`. Figure 10–4 is an example of the contents of a power estimation file generated by the Quartus II software version 7.2 using a Stratix II device.

## PowerPlay Early Power Estimator File Generator Compilation Report

After successfully generating the power estimation file, a PowerPlay Early Power Estimator File Generator report is created under the Compilation Report section. This report is divided into the different sections, such as Summary, Settings, Generated Files, Confidence Metric Details, and Signal Activities.

For more information about the PowerPlay Early Power Estimator File Generator report, refer to “[PowerPlay Power Analyzer Compilation Report](#)” on page 10–39.

[Table 10–1](#) lists the main differences between the PowerPlay Early Power Estimator and the PowerPlay Power Analyzer.

Characteristic	PowerPlay Early Power Estimator	PowerPlay Power Analyzer
Phase in the design cycle	Any time	After fitting
Tool requirements	Spreadsheet program/Quartus II software	Quartus II software
Accuracy	Medium	Medium to very high
Data inputs	<ul style="list-style-type: none"> <li>• Resource usage estimates</li> <li>• Clock requirements</li> <li>• Environmental conditions</li> <li>• Toggle Rate</li> </ul>	<ul style="list-style-type: none"> <li>• Design after fitting</li> <li>• Clock requirements</li> <li>• Register transfer level (RTL) simulation results (optional)</li> <li>• Post-fitting simulation results (optional)</li> <li>• Signal activities per node or entity (optional)</li> <li>• Signal activity defaults</li> <li>• Environmental conditions</li> </ul>
Data outputs <sup>(1)</sup>	<ul style="list-style-type: none"> <li>• Total thermal power dissipation</li> <li>• Thermal static power</li> <li>• Thermal dynamic power</li> <li>• Off-chip power dissipation</li> <li>• Voltage supply currents <sup>(2)</sup></li> </ul>	<ul style="list-style-type: none"> <li>• Total thermal power</li> <li>• Thermal static power</li> <li>• Thermal dynamic power</li> <li>• Thermal I/O power</li> <li>• Thermal power by design hierarchy</li> <li>• Thermal power by block type</li> <li>• Thermal power dissipation by clock domain</li> <li>• Off-chip (non-thermal) power dissipation</li> <li>• Voltage supply currents <sup>(2)</sup></li> </ul>

### Notes to Table 10–1:

- (1) Early Power Estimator output varies by device family as some features may not be available.
- (2) Available only for Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

The results of the Power Analyzer are only an estimation of power, not a specification. The purpose of the estimation is to help establish a guide for the design's power budget. Altera recommends that the actual power be measured on the board. You must measure the device's total dynamic current during device operation, because the estimate is very design dependent and depends on many variable factors, including input vector quantity, quality, and exact loading conditions of a PCB design. Static power consumption must not be based on empirical observation. The values reported by the Power Analyzer or datasheet must be used because the devices tested may not exhibit worst-case behavior.

## Types of Power Analyses

Understanding the uses of power analysis and the factors affecting power consumption help you use the Power Analyzer effectively. Power analysis meets two significant planning requirements:

- **Thermal planning:** The designer must ensure that the cooling solution is sufficient to dissipate the heat generated by the device. In particular, the computed junction temperature must fall within normal device specifications.
- **Power supply planning:** Power supplies must provide adequate current to support device operation.

The two types of analyses are closely related because much of the power supplied to the device is dissipated as heat from the device. However, in some situations, the two types of analyses are not identical. For example, when you use terminated I/O standards, some of the power drawn from the FPGA device power supply is dissipated in termination resistors, rather than in the FPGA.

Power analysis also addresses the activity of the design over time as a factor that impacts the power consumption of the device. Static power is defined as the power consumed regardless of design activity. Dynamic power is the additional power consumed due to signal activity or toggling.

## Factors Affecting Power Consumption

This section describes the factors affecting power consumption. Understanding these factors lets you use the Power Analyzer and interpret its results effectively.

### Device Selection

Different device families have different power characteristics. Many parameters affect the device family power consumption, including choice of process technology, supply voltage, electrical design, and device

architecture. For example, the Cyclone II device family architecture was designed to consume less static power than the high-performance, full-featured, Stratix II device family.

Power consumption also varies within a single device family. A larger device typically consumes more static power than a smaller device in the same family, due to its larger transistor count. Dynamic power can also increase with device size in devices that employ global routing architectures, such as the MAX device family. Stratix, Cyclone, and MAX II devices do not exhibit significantly increased dynamic power as device size increases.

The choice of device package also affects the device's ability to dissipate heat. This can impact your cooling solution choice required to meet junction temperature constraints.

Finally, process variation can affect power consumption. Process variation primarily impacts static power, since sub-threshold leakage current varies exponentially with changes in transistor threshold voltage. As a result, it is critical to consult device specifications for static power and not rely on empirical observation. Process variation weakly affects dynamic power.

### **Environmental Conditions**

Operating temperature primarily affects device static power consumption. Higher junction temperatures result in higher static power consumption. The device thermal power and cooling solution that you use must result in the device junction temperature remaining within the maximum operating range for that device.

The main environmental parameters affecting junction temperature are the cooling solution and ambient temperature.

#### *Air Flow*

Air flow is a measure of how quickly heated air is removed from the vicinity of the device and replaced by air at ambient temperature. This can either be specified as "still air" when no fan is used, or as the linear feet per minute rating of the fan used in the system. Higher air flow decreases thermal resistance.

#### *Heat Sink and Thermal Compound*

A heat sink allows more efficient heat transfer from the device to the surrounding area because of its large surface area exposed to the air. The thermal compound that interfaces the heat sink to the device also

influences the rate of heat dissipation. The case-to-ambient thermal resistance ( $\theta_{CA}$ ) parameter describes the cooling capacity of the heat sink and thermal compound employed at a given airflow. Larger heat sinks and more effective thermal compounds reduce  $\theta_{CA}$ .

### *Ambient Temperature*

The junction temperature of a device is equal to:

$$T_{\text{Junction}} = T_{\text{Ambient}} + P_{\text{Thermal}} \cdot \theta_{JA}$$

where  $\theta_{JA}$  is the total thermal resistance from the device transistors to the environment, having units of degrees Celsius per Watt. The value  $\theta_{JA}$  is equal to the sum of the junction-to-case (package) thermal resistance ( $\theta_{JC}$ ) and the case-to-ambient thermal resistance ( $\theta_{CA}$ ) of your cooling solution.

### *Board Thermal Model*

The thermal resistance of the path through the board is referred to as the junction-to-board thermal resistance ( $\theta_{JB}$ ) (the units are in degrees Celsius per Watt). This is used in conjunction with the board temperature, as well as the top-of-chip  $\theta_{JA}$  and ambient temperatures, to compute junction temperature.

## **Design Resources**

The design resource used greatly affects power consumption.

### *Number, Type, and Loading of I/O Pins*

Output pins drive off-chip components, resulting in high-load capacitance that leads to a high-dynamic power per transition. Terminated I/O standards require external resistors that generally draw constant (static) power from the output pin.

### *Number and Type of Logic Elements, Multiplier Elements, and RAM Blocks*

A design with more logic elements (LEs), multiplier elements, and memory blocks tends to consume more power than a design with fewer such circuit elements. Also, the operating mode of each circuit element affects its power consumption. For example, a digital signal processing (DSP) block performing  $18 \times 18$  multiplications and a DSP block performing multiply-accumulate operations consume different amounts

of dynamic power due to different amounts of internal capacitance being charged on each transition. Static power is also affected, to a small degree, by the operating mode of a circuit element.

### *Number and Type of Global Signals*

Global signal networks span large portions of the device and have high capacitance, resulting in significant dynamic power consumption. The type of global signal is important as well. For example, Stratix II devices support several kinds of global clock networks that span either the entire device or a specific portion of the device (a regional clock network covers a quarter of the device). Clock networks that span smaller regions have lower capacitance and therefore, tend to consume less power. In addition, the location of the logic array blocks (LABs) that are driven by the clock network can have an impact, because the Quartus II software automatically disables unused branches of a clock.

### **Signal Activities**

The final important factor in estimating power consumption is the behavior of each signal in the design. The two vital statistics are the toggle rate and the static probability.

The toggle rate of a signal is the average number of times that the signal changes value per unit time. The units for toggle rate are transitions per second, and a transition is a change from 1 to 0 or 0 to 1.

The static probability of a signal is the fraction of time that the signal is logic 1 during the period of device operation that is being analyzed. Static probability ranges from 0 (always at ground) to 1 (always at logic high).

Dynamic power increases linearly with the toggle rate as the capacitive load is charged more frequently for logic and routing. The Quartus II models assume full rail-to-rail switching. For high toggle rates, especially on circuit output I/O pins, the circuit can transition before fully charging downstream capacitance. The result is a slightly conservative prediction of power by the Quartus II PowerPlay Power Analyzer.

The static power consumed by both routing and logic can sometimes be affected by the static probabilities of their input signals. This effect is due to state-dependent leakage, and has a larger affect on smaller process geometries. The Quartus II software models this effect on devices at 90 nm (or smaller) if it is deemed important to the power estimate. The static power also varies with the static probability of a logic 1 or 0 on the I/O pin when output I/O standards drive termination resistors.

To get accurate results from power analysis, the signal activities that are used for analysis must be representative of the actual operating behavior of the design. Inaccurate signal toggle rate data is the largest source of power estimation error.

## PowerPlay Power Analyzer Flow

The PowerPlay Power Analyzer supports accurate and representative power estimation by letting you specify all the important design factors affecting power consumption. [Figure 10-5](#) shows the high-level Power Analyzer flow.

**Figure 10-5. PowerPlay Power Analyzer High-Level Flow**

**Note to [Figure 10-5](#):**

- (1) Operating condition specifications are available only for the Arria GX devices, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

The PowerPlay Power Analyzer requires that your design is synthesized and fit to the target device. Therefore, the Power Analyzer knows both the target device and how the design is placed and routed on the device. The electrical standard used by each I/O cell and the capacitive load on each I/O standard must be specified in the design to obtain accurate I/O power estimates.

## Operating Conditions

For the Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families, you can specify the operating conditions for power analysis in the Quartus II software.

The following settings are available in the **Settings** dialog box:

- **Device power characteristics**—Should the Power Analyzer assume typical silicon or maximum power silicon? The typical setting is useful for comparing to empirical data measured on an average unit. Worst-case data provides a boundary to the worst-case device that you could receive.
- **Selectable Core Voltage**—You can select a suitable core supply voltage for your design based on performance and power requirements using the **Core Supply Voltage** option, available for the latest devices with variable voltage support. The power consumption of a device is heavily dependent on the voltage, so it is very important to choose the right core supply voltage for your design. The core supply voltage provides power to device logic resources such as logic array blocks (LABs), MLABs, DSP functions, memory, and interconnects.
- **Environmental conditions and junction temperature**—By default, the Power Analyzer automatically computes the junction temperature based on the specified ambient temperature and the cooling solution that you selected from a list. For a more accurate analysis, enter the thermal resistance of your cooling solution. For some cooling solutions, such as a heat sink with no forced airflow, the thermal resistance varies with the amount of thermal power that is dissipated. Air convection increases as the difference between the device temperature and the ambient temperature increases, reducing thermal resistance. When entering a thermal resistance in such cases, it is important to use the thermal resistance that occurs when the heat flow ( $Q$ ) is equal to the thermal power generated by the device. You can also specify a junction temperature in the PowerPlay Power Analyzer. However, Altera does not recommend this because the PowerPlay Power Analyzer provides more accurate results by computing the junction temperature.
- **Board Thermal Modeling**—If you want the Power Analyzer thermal model to take the  $\theta_{JB}$  into consideration, set the board thermal model to either **Typical** or **Custom**. This feature produces more accurate thermal power estimation.

A **Typical** board thermal model automatically sets  $\theta_{JB}$  to a value based on the package and device selected. You only need to specify a board temperature. If you choose a **Custom** board thermal model,

you must specify a value for  $\theta_{JB}$  and a board temperature. If you do not want the PowerPlay Power Analyzer thermal model to take the  $\theta_{JB}$  resistance into consideration, set the **Board thermal model** option to **None** (conservative). In this case, the path through the board and power dissipation is not considered, and a more conservative thermal power estimate is obtained.

The **Board thermal model** option is only available if you select the **Auto compute junction temperature** option with the pre-set cooling solution set to some heat sink solution option or custom solution. This option is disabled when a cooling solution with no heat sink is selected, as thermal conduction through the board is included in the  $\theta_{JA}$  value used to compute a junction temperature in that case.

## Signal Activities Data Sources

The Power Analyzer provides a flexible framework for specifying signal activities. This reflects the importance of using representative signal activity data during power analysis. You can use the following sources to provide information about signal activity:

- Simulation results
- User-entered node, entity, and clock assignments
- User-entered default toggle rate assignment
- Vectorless estimation

The PowerPlay Power Analyzer lets you mix and match the signal activity data sources on a signal-by-signal basis. [Figure 10–6](#) shows the priority scheme. The data sources are described in the following sections.

Figure 10–6. Signal Activity Data Source Priority Scheme

**Note to Figure 10–6:**

(1) Vectorless estimation is available only for the Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone II, HardCopy II, and MAX II device families.

### Simulation Results

The Power Analyzer directly reads the waveforms generated by a design simulation. The static probability and toggle rate for each signal is calculated from the simulation waveform. Power analysis is most accurate when simulations are generated using representative input stimuli.

The Power Analyzer reads the results generated by the following simulators:

- Quartus II Simulator
- ModelSim® VHDL, Active HDL, ModelSim Verilog HDL, ModelSim-Altera VHDL, ModelSim-Altera Verilog
- NC-Verilog, NC-VHDL
- VCS

Signal activity and static probability information are stored in a Signal Activity File (.saf) or may be derived from a Value Change Dump File (.vcd), described in “Signal Activities” on page 10–9. The Quartus II simulator generates a Signal Activity File (SAF) or a Value Change Dump (VCD) file which is then read by the Power Analyzer.

For third-party simulators, use the Quartus II EDA Tool Settings for Simulation to specify a **Generate Value Change Dump** file script. These scripts instruct the third-party simulators to generate a VCD file that encodes the simulated waveforms. The Quartus II Power Analyzer reads this file directly to derive toggle rate and static probability data for each signal.

Third-party EDA simulators, other than those listed above, can generate a VCD file that can then be used with the Power Analyzer. For those simulators, it is necessary to manually create a simulation script to generate the appropriate Value Change Dump File.

You can use a SAF or VCD file created for power analysis to optimize the design for power during fitting by utilizing the appropriate settings in the **PowerPlay power optimization** list, available in **Fitter Settings** page of the **Settings** dialog box.

For more information about power optimization, refer to the *Power Optimization* chapter in volume 2 of the *Quartus II Handbook*.

## Using Simulation Files in Modular Design Flows

A common design practice is to create modular or hierarchical designs in which you develop each design entity separately and then instantiate it in a higher-level entity, forming a complete design. Simulation is performed on a complete design or on each modular design for verification. The Quartus II PowerPlay Power Analyzer Tool supports modular design flows when reading the signal activities generated from these simulation files, as shown in Figure 10-7.

**Figure 10-7. Modular Simulation Flow**

When specifying a simulation file, an associated design entity name may be given, such that the signal activities derived from the simulation file (VCD file or SAF) can be imported into the Power Analyzer for that particular design entity. The PowerPlay Power Analyzer Tool also supports the specification of multiple SAFs for power analysis with each having an associated design entity name to allow the integration of partial design simulations into a complete design power analysis. When specifying multiple SAFs for your design, it is possible that more than one simulation file will contain signal activity information for the same signal. In the case where multiple SAFs are applied to the same design entity, the signal activity used in the power analysis is the equal-weight arithmetic average of each SAF. Also in the case where multiple simulation files are applied to design entities at different levels in the design hierarchy, the signal activity used in the power analysis is derived from the simulation file that is applied to the most specific design entity.

Figure 10-8 shows an example of a hierarchical design. The design Top consists of three 8b/10b Decoders, followed by a multiplexer whose output is then encoded again before being output from the design. There is also an error-handling module that handles any 8b/10b decoding errors. The top-level module, called Top, automatically contains the design's top-level entity and any logic not defined as part of another module. The design file for the top-level module may be just a wrapper

for the hierarchical entities below it, or it may contain its own logic. The following usage scenarios show common ways that you may simulate your design and import SAFs into the PowerPlay Power Analyzer Tool.

**Figure 10–8. Example Hierarchical Design**

## Complete Design Simulation

You can simulate the entire design `Top`, generating a VCD file if you use a third-party simulator, or generating a SAF or VCD if you use the Quartus II Simulator. The VCD file or SAF can then be imported (specifying Entity `Top`) into the power analyzer. The resulting power analysis uses all the signal activities information from the generated VCD file or SAF, including those that apply to submodules, such as `decode [1-3]`, `err1`, `mux1`, and `encode1`.

## Modular Design Simulation

You can simulate submodules of the design `Top` independently, and then import all of the resulting SAFs into the Power Analyzer. For example, you may simulate the `8b10b_dec` independent of the entire design, as well as multiplexer, `8b10b_rxerr`, and `8b10b_enc`. You can then import the VCD file or SAF generated from each simulation by specifying

the appropriate instance name. For example, if the files produced by the simulations are **8b10b\_dec.vcd**, **8b10b\_enc.vcd**, **8b10b\_rxerr.vcd**, and **mux.saf**, the import specifications in [Table 10–2](#) are used.

File Name	Entity
<b>8b10b_dec.vcd</b>	Top   8b10b_dec:decode1
<b>8b10b_dec.vcd</b>	Top   8b10b_dec:decode2
<b>8b10b_dec.vcd</b>	Top   8b10b_dec:decode3
<b>8b10b_rxerr.vcd</b>	Top   8b10b_rxerr:err1
<b>8b10b_enc.vcd</b>	Top   8b10b_enc:encode1
<b>mux.saf</b>	Top   mux:mux1

The resulting power analysis applies the simulation vectors found in each file to the assigned entity. Simulation provides signal activities for the pins and for the outputs of functional blocks. If the inputs to an entity instance are input pins for the entire design, the simulation file associated with that instance does not provide signal activities for the inputs of that instance. For example, an input to an entity such as `mux1` has its signal activity specified at the output of one of the decode entities.

### Multiple Simulations on the Same Entity

You can perform multiple simulations of an entire design or specific modules of a design. For example, in the process of verifying the Top design, you may have three different simulation testbenches: one for normal operation, and two for corner cases. Each of these simulations produces a separate VCD file or SAF. In this case, apply the different VCD file or SAF names to the same top-level entity, shown in [Table 10–3](#).

File Name	Entity
<b>normal.saf</b>	Top
<b>corner1.vcd</b>	Top
<b>corner2.vcd</b>	Top

The resulting power analysis uses an arithmetic average of the signal activities calculated from each simulation file to obtain the final signal activities used. Thus, if a signal `err_out` has a toggle rate of 0 toggles per

second in **normal.saf**, 50 toggles per second in **corner1.vcd**, and 70 toggles per second in **corner2.vcd**, the final toggle rate that is used in the power analysis is 40 toggles per second.

## Overlapping Simulations

You can perform a simulation on the entire design Top and more exhaustive simulations on a submodule, such as `8b10b_rxerr`. [Table 10–4](#) shows the import specification for overlapping simulations.

<i>Table 10–4. Overlapping Simulation Import Specifications</i>	
File Name	Entity
<b>full_design.vcd</b>	Top
<b>error_cases.vcd</b>	Top   8b10b_rxerr:err1

In this case, signal activities from **error\_cases.vcd** are used for all of the nodes in the generated SAF, and signal activities from **full\_design.vcd** are used for only those nodes that do not overlap with nodes in **error\_cases.vcd**. In general, the more specific hierarchy (the most bottom-level module) is used to derive signal activities for overlapping nodes.

## Partial Simulations

You can perform a simulation where the entire simulation time is not applicable to signal activity calculation. For example, suppose you run a simulation for 10,000 clock cycles and you reset the chip for the first 2,000 clock cycles. If the signal activity calculation is performed over all 10,000 cycles, the toggle rates are typically only 80% of their steady state value (since the chip is in reset for the first 20% of the simulation). In this case, you should specify the useful parts of the VCD file for power analysis. The Limit VCD Period option enables you to specify a start and end time to be used when performing signal activity calculations.

## Node Name Matching Considerations

Node name mismatches happen when you have SAFs or VCD files applied to entities other than the top-level entity. In a modular design flow, the gate-level simulation files created in different Quartus II software projects may not match their node names properly with the current Quartus II project.

For example, if you have a file named **8b10b\_enc.vcd**, which was generated in a separate project called **8b10b\_enc** and is simulating the 8b10b encoder, and you import that VCD file into another project called **Top**, you may encounter name mismatches when applying the VCD file to the 8b10b\_enc module in the **Top** project. This is because all of the combinational nodes in the **8b10b\_enc.vcd** file may be named differently in the **Top** project.

You can avoid name mismatching by using only register transfer level (RTL) simulation data, where register names usually do not change, or by using an incremental compile flow that preserves node names in conjunction with a gate-level simulation. To ensure the best accuracy, Altera recommends using an incremental compile flow to preserve your design's node names.

For more information about the incremental compile flow, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

## Glitch Filtering

The Power Analyzer defines a glitch as two signal transitions that are so closely spaced in time that the pulse, or glitch, occurs faster than the logic and routing circuitry can respond. The output of a transport delay model simulator (the default mode of the Quartus II simulator) generally contains glitches for some signals. The device's logic and routing structures form a low-pass filter that filters out glitches that are tens to hundreds of picoseconds long, depending on the device family.

Some third-party simulators use different simulator models than the transport delay model as default. Different models cause differences in signal activity estimation and power estimation. The inertial delay model, which is the ModelSim default model, filters out many more glitches than the transport delay model; therefore, it usually yields a lower power estimate. Altera recommends using the transport simulation model when using the Quartus II glitch filtering support with third-party simulators. If the inertial simulation model is used, simulation glitch filtering has little effect.

For more information about how to set the simulation model type for your specific simulator, refer to the Quartus II Help.

Glitch filtering in a simulator can also filter a glitch on one LE (or other circuit element) output from propagating to downstream circuit elements so that the glitch will not affect simulated results. This prevents a glitch on one signal from producing non-physical glitches on all downstream logic, which would result in a signal toggle rate that is too high and a

power estimate that is too high. Circuit elements in which every input transition produces an output transition, including multipliers and logic cells configured to implement XOR functions, are especially prone to glitches. Therefore, circuits with many such functions can have power estimates that are too high when glitch filtering is not used.

Altera recommends that the glitch filtering feature be used to obtain the most accurate power estimates. For VCD files, the Power Analyzer flows support two types of glitch filtering, both of which are recommended for power estimation. In the first, glitches are filtered during simulation. To enable this level of glitch filtering in the Quartus II software for supported third-party simulators, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears.
3. Select the **Tool Name** to use for the simulation.
4. Turn on the **Enable glitch filtering** option.

To enable this level of glitch filtering in the Quartus II software using the Quartus II Simulator, refer to [“Generating a SAF or VCD File Using the Quartus II Simulator”](#) on page 10–24.

The second level of glitch filtering occurs while the Power Analyzer is reading the VCD file generated by the third-party simulator or Quartus II Simulator. Enable this level of glitch filtering by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **PowerPlay Power Analyzer Settings**. The **PowerPlay Power Analyzer Settings** page appears.
3. Under **Input File(s)**, turn on the **Perform glitch filtering on VCD files** option.

Altera recommends that you use both forms of glitch filtering.

The VCD file reader performs complementary filtering to the filtering performed during simulation and is often not as effective. While the VCD file reader can remove glitches on logic blocks, it has no way of determining how downstream logic and routing are affected by a given

glitch, and may not eliminate the impact of the glitch completely. Filtering the glitches during simulation avoids switching downstream routing and logic automatically.

When running simulation for design verification (rather than to produce input to the Quartus PowerPlay Power Analyzer), Altera recommends leaving glitch filtering turned off. This produces the most rigorous and conservative simulation from a functionality viewpoint. When performing simulation to produce input for the Quartus II PowerPlay Power Analyzer, Altera recommends turning on glitch filtering to produce the most accurate power estimates.

## Node and Entity Assignments

You can assign specific toggle rates and static probabilities to individual nodes and entities in the design. These assignments have the highest priority, overriding data from all other signal activity sources.

Use the Assignment Editor or tool command language (Tcl) commands to make the **Power Toggle Rate** and **Power Static Probability** assignments. You can specify the power toggle rate as an absolute toggle rate in transitions using the **Power Toggle Rate** assignment or you can use the **Power Toggle Rate Percentage** assignment to specify a toggle rate relative to the clock domain of the assigned node for more specific assignment made in terms of hierarchy level.

If the **Power Toggle Rate Percentage** assignment is used, and the given node does not have a clock domain, a warning is issued and the assignment is ignored.

For more information about how to use the Assignment Editor in the Quartus II software, refer to the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*.

This method is appropriate for special-case signals where you have specific knowledge of the signal or entity being analyzed. For example, if you know that a 100-MHz data bus or memory output produces data that is essentially random (uncorrelated in time), you can directly enter a 0.5 static probability and a toggle rate of 50 million transitions per second.

Bidirectional I/O pins are treated specially. The combinational input port and the output pad for a given pin share the same name. However, those ports might not share the same signal activities. For the purpose of reading signal activity assignments, the Power Analyzer creates a distinct name `<node_name~output>` when the bidirectional signal is configured as an output and `<node_name~result>` when the signal is

configured as an input. For example, if a design has a bidirectional pin named MYPIN, assignments for the combinational input use the name MYPIN~result, and the assignments for the output pad use the name MYPIN~output.

 When making the logic assignment in the Assignment Editor, you will not find the MYPIN~result and MYPIN~output node names in the Node Finder. Therefore, to make the logic assignment, you must manually enter the two differentiating node names to make the specific assignment for the input and output port of the bidirectional pin.

### *Timing Assignments to Clock Nodes*

For clock nodes, the Power Analyzer uses the timing requirements to derive the toggle rate when neither simulation data nor user entered signal activity data is available.

  $f_{\text{MAX}}$  requirements specify full cycles per second, but each cycle represents a rising transition and a falling transition. For example, a clock  $f_{\text{MAX}}$  requirement of 100 MHz corresponds to 200 million transitions per second.

### **Default Toggle Rate Assignment**

You can specify a default toggle rate for primary inputs and all other nodes in the design. The default toggle rate is used when no other method has specified the signal activity data.

The toggle rate can be specified in absolute terms (transitions per second) or as a fraction of the clock rate in effect for each particular node. The toggle rate for a given clock is derived from the timing settings for the clock. For example, if a clock is specified with an  $f_{\text{MAX}}$  constraint of 100 MHz and a default relative toggle rate of 20%, nodes in this clock domain transition in 20% of the clock periods, or 20 million transitions occur per second. In some cases, the Power Analyzer cannot determine the clock domain for a given node because there is either no clock domain for the node or it is ambiguous. In these cases, the Power Analyzer substitutes and reports a toggle rate of zero.

## Vectorless Estimation

For some device families, the Power Analyzer automatically derives estimates for signal activity on nodes with no simulation or user-entered signal-activity data. Vectorless estimation is available and enabled by default for Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families. Vectorless estimation statistically estimates the signal activity of a node based on the signal activities of all nodes feeding that node, and on the actual logic function that is implemented by the node. The PowerPlay Power Analyzer **Settings** dialog box lets you disable vectorless estimation. When enabled, vectorless estimation takes priority over default toggle rates. Vectorless estimation does not override clock assignments.

Vectorless estimation cannot derive signal activities for primary inputs. Vectorless estimation is generally accurate for combinational nodes, but not for registered nodes. Therefore, simulation data for at least the registered nodes and I/O nodes is needed for accuracy.

## Using the PowerPlay Power Analyzer

For all flows that use the PowerPlay Power Analyzer, synthesize your design first and then fit it to the target device. You must either provide timing assignments for all clocks in the design or use a simulation-based flow to generate activity data. The I/O standard used on each device input or output and the capacitive load on each output must be specified in the design.

### Common Analysis Flows

You can use the analysis flows in this section with the PowerPlay Power Analyzer. However, vectorless activity estimation is only available for some device families.

#### *Signal Activities from Full Post-Fit Netlist (Timing) Simulation*

This flow provides the highest accuracy because all node activities reflect actual design behavior, provided that supplied input vectors are representative of typical design operation. Results are better if the simulation filtered glitches. The disadvantage with this method is that simulation times can be long.

### *Signal Activities from RTL (Functional) Simulation, Supplemented by Vectorless Estimation*

In this flow, simulation provides toggle rates and static probabilities for all pins and registers in the design. Vectorless estimation fills in the values for all the combinational nodes between pins and registers. This method yields good results, since vectorless estimation is accurate, given that the proper pin and register data is provided. This flow usually provides a compilation time benefit to the user in the third-party RTL Simulator.

RTL simulation may not provide signal activities for all registers in the post-fitting netlist because some register names may be lost during synthesis. For example, synthesis may automatically transform state machines and counters, thus changing the names of registers in those structures.

### *Signal Activities from Vectorless Estimation, User-Supplied Input Pin Activities*

This option provides a low level of accuracy, because vectorless estimation for registers is not entirely accurate.

### *Signal Activities from User Defaults Only*

This option provides the lowest degree of accuracy.

## **Generating a SAF or VCD File Using the Quartus II Simulator**

While performing a timing or functional simulation using the Quartus II Simulator, you can generate a SAF or VCD file. These files store the toggle rate and static probability for each connected output signal based on the simulation vectors that are entered in the Vector Waveform File (.vwf) or the Vector File (.vec). You can use the SAF(s) or VCD file(s) as input to the PowerPlay Power Analyzer to estimate power for your design.

For more accurate results, Altera recommends that you use the SAF created from the Quartus II simulator as the input to the PowerPlay Power Analyzer.

To create a SAF or VCD file for your design, perform the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulator Settings**. The **Simulator Settings** page appears (Figure 10-9).

Figure 10–9. Simulator Settings Page

3. In the **Simulation mode** list, select either **Timing** or **Functional**. Refer to “[Common Analysis Flows](#)” on page 10–23 for a description of the difference in accuracy between the two types of simulation modes.
4. (Optional) Click **More Settings**. The **More Simulator Settings** dialog box appears.
5. (Optional) Turn on glitch filtering. To turn on glitch filtering, in the **Glitch filtering options** list, select **Always**.
6. In the **Category** list, click the  icon to expand **Simulator Settings** and select **Simulation Output Files** ([Figure 10–10](#)).

**Figure 10–10. Simulator Output Files Page of the Settings Dialog Box**

7. Turn on **Generate Signal Activity File** and enter the file name for the SAF file.

For more information about the Quartus II Simulator and how to create a SAF file, refer to the *Quartus II Simulator* chapter in volume 3 of the *Quartus II Handbook*.

When generating a VCD file from the Quartus Simulator, you must make sure that you add **all nodes** to the input vector wave file. Only the nodes that have been added to your vector file will be output to the Quartus-generated VCD file. This is not the case when generating a SAF. The Quartus II Simulator will create a SAF including all the internal nodes of your design even if the stimuli file contains only the input vectors for your simulation.

8. (Optional) Click **Signal Activity File Options**. The **Signal Activity File Options** dialog box appears (Figure 10–11).

**Figure 10–11. Signal Activity File Options Dialog Box**

9. (Optional) Turn on the **Limit signal activity period** option to specify the simulation period to use when calculating the signal activities.

Power estimation can be performed for the entire simulation time or for a portion of the simulation time. This allows you to look at the power consumption at different points in your overall simulation without having to rework your testbenches. This feature is also useful when multiple clock cycles are necessary to initialize the state of the design, but you want to measure the signal activity only during the normal operation of the design, not during its initialization phase. You can specify the start time and end time in the **Signal Activity File Options** dialog box by turning on the **Limit signal activity period** option. Simulation information is used during this time interval only to calculate toggle rates and static probabilities. If no time interval is specified, the whole simulation is used to compute signal activity data.

10. After the simulation is complete, a SAF is generated with the specified filename and stored in the main project directory.

For more information about how to perform simulations in the Quartus II software, see the Quartus II Help.

## Generating a VCD File Using a Third-Party Simulator

You can use other EDA simulation tools, such as the Model Technology™ ModelSim® software, to perform a simulation and create a VCD file. You can use this file as input to the PowerPlay Power Analyzer to estimate power for your design. To do this, you must tell the Quartus II software to generate a script file that is used as input to the third-party simulator. This script tells the third-party simulator to generate a VCD file that contains all the output signals. For more information about the supported third-party simulators, refer to “Simulation Results” on page 10–13.

To create a VCD file for your design, perform the following steps:

1. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **Simulation**. The **Simulation** page appears, as shown in [Figure 10–12](#).

**Figure 10–12. Simulation Page of the Settings Dialog Box**

3. In the **Tool name** list, select the appropriate EDA simulation tool.

4. In the **Format for output netlist** list, select **VHDL** or **Verilog**.
5. Turn on **Generate Value Change Dump (VCD) file script**.

This turns on the **Map illegal HDL character** and **Enable glitch filtering** options.

6. (Optional) **Map illegal HDL characters** ensures that all signals have legal names and that signal toggle rates are available later in the PowerPlay Power Analyzer.
7. (Optional) By turning on **Enable glitch filtering**, glitch filtering logic is the output when you generate an EDA netlist for simulation. This option is always available, regardless of whether or not you want to generate the VCD file scripts. For more information about glitch filtering, refer to [“Glitch Filtering” on page 10–19](#).

When performing simulation using ModelSim, the **+nospecify** option given to the `vsim` command disables **specify** path delays and timing checks in ModelSim. By enabling glitch filtering on the **Simulation** page, the simulation models include **specify** path delays. Thus, ModelSim can fail to simulate a design if glitch filtering is enabled and the **+nospecify** option is specified. Altera recommends the removal of the **+nospecify** option from the ModelSim `vsim` command to ensure accurate simulation for power estimation.

8. Click **Script Settings**. The **Script Settings** dialog box appears, shown in [Figure 10–13](#).

**Figure 10–13. Script Settings Dialog Box**

Select which signals should be output to the VCD file. With **All signals** selected, the generated script instructs the third-party simulator to write all connected output signals to the VCD file. With **All signals except combinational lcell outputs** selected, the

generated script tells the third-party simulator to write all connected output signals to the VCD file, except logic cell combinational outputs. You may not want to write all output signals to the file because the file can become extremely large (since its size depends on the number of output signals being monitored and the number of transitions that occur).

9. Click **OK**.
10. Type a name for your testbench in the **Design instance name** box.
11. Compile your design with the Quartus II software and generate the necessary EDA netlist and script that tells the third-party simulator to generate a VCD file.

For more information about NativeLink use, refer to *Section I. Simulation* in volume 3 of the *Quartus II Handbook*.

12. Perform a simulation with the third-party EDA simulation tool. Call the generated script in the simulation tool before running the simulation. The simulation tool generates the VCD file and places it in the project directory.

The following example provides step-by-step instructions to successfully produce a VCD file with the ModelSim software:

1. In the Quartus II software, on the Assignments menu, click **Settings**.
2. In the **Settings** dialog box, on the **Simulator Settings** page, choose the appropriate ModelSim selection in the **Tool Name** list, and turn on the **Generate Value Change Dump File Script** option.
3. To generate the VCD file, perform a full compilation.
4. In the ModelSim software, compile the files necessary for simulation.
5. Load your design by clicking **Start Simulation** on the Tools menu, or use the **vsim** command.
6. Source the Quartus II VCD script created in step 3 using the following command:  

```
source <design>_dump_all_vcd_nodes.tcl
```
7. Run the simulation (for example, **run 2000ns** or **run -all**).
8. Quit the simulation using the **quit -sim** command, if needed.

- Exit the ModelSim software. If you do not exit the software, the ModelSim software may end the writing process of the VCD files improperly, resulting in a corrupted VCD file.

For more information about how to call the VCD file generation script in the respective third-party EDA simulation tools, refer to the Quartus II Help. For more information about how to perform simulations in other EDA simulation tools, see the relevant documentation for that tool.

## Running the PowerPlay Power Analyzer Using the Quartus II GUI

To run the PowerPlay Power Analyzer using the Quartus II GUI, perform the following steps:

- On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
- In the **Category** list, select **PowerPlay Power Analyzer Settings**, shown in [Figure 10–14](#).

**Figure 10–14. PowerPlay Power Analyzer Settings**

- (Optional) If you want to use either SAF(s) or VCD file(s) or both as an input to the PowerPlay Power Analyzer, turn on **Use input file(s) to initialize toggle rates and static probabilities during power analysis**.

(Optional) The **Edit** button allows you to change the settings for a selected file from the list. The **Remove** button allows you to remove a selected file from the list.

- Click **Add**. The **Add Power Input File** dialog box appears, as shown in [Figure 10-15](#).

**Figure 10-15. Add Power Input File Dialog Box**

- Add your SAF(s) or VCD file(s) by clicking the browse button for the **File name** box.
- The **Entity** box enables you to specify the design entity (hierarchy) to which the entered power input file applies. To enter the entity, you can type in the box or browse through the list of your design entities. To browse your design entities, click the browse button. The **Select Hierarchy** dialog box appears, shown in [Figure 10-16](#). You can specify multiple entities in the entity text box by using comma delimiters.

**Figure 10–16. Select Hierarchy Dialog Box**

7. You can specify whether the input file is a VCD file or SAF under **Input File Type**.
8. (Optional) **Limit VCD period** is enabled only when the **VCD file** is selected. This enables you to specify the simulation period to use when calculating the signal activities. For more information, refer to step 9 of [“Generating a SAF or VCD File Using the Quartus II Simulator”](#) on page 10–24.
9. Click **OK**.
10. Click **OK** in the **Add Power Input File** dialog box.
11. (Optional) Turn on **Perform glitch filtering on VCD files**. This option is recommended. For more information, refer to [“Glitch Filtering”](#) on page 10–19.
12. (Optional) Turn on **Write out signal activities used during power analysis**. In the **Output file name** list, select the output file name. This file contains all the signal activities information used during the power estimation of your design. This is recommended if you

used a VCD file as input into the PowerPlay Power Analyzer, because it reduces the run time of any subsequent power estimation. You can use the generated SAF as input instead of the original VCD file.

13. (Optional) Turn on **Write signal activities to report file**.
14. (Optional) Turn on **Write power dissipation by block to report file** to enable the output of detailed thermal power dissipation by block to be included in the PowerPlay Power Analyzer report.
15. (Optional) You can also use the Assignment Editor to enter the Power Toggle Rate or Power Toggle Rate Percentage, and the Power Static Probability for a node or entity in your design, shown in [Figure 10-17](#).

**Figure 10-17. Assignment Editor** Notes (1), (2)

**Notes to Figure 10-17:**

- (1) The assignments made with the Assignment Editor override the values already existing in the SAF or VCD file.
- (2) You can also use Tcl script commands to make these assignments.

For more information about how to use the Assignment Editor in the Quartus II software, see the *Assignment Editor* chapter in volume 2 of the *Quartus II Handbook*. For information about scripting, see the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

16. Specify the toggle rate in the **Default toggle rate used for input I/O signals** field. This toggle rate is used for all unspecified input I/O signal toggle rates regardless of whether or not the device family supports vectorless estimation. By default, its value is set to 12.5%. The default static probability for unspecified input I/O signals is 0.5 and cannot be changed.
17. Select either **Use default value** or **Use vectorless estimation** for Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, or MAX II device families. For all other device families, only **Use default value** is available. This setting controls how the remainder of the unspecified signal activities are calculated. For more information, refer to [“Vectorless Estimation” on page 10–23](#) and [“Default Toggle Rate Assignment” on page 10–22](#).
18. In the **Category** list, select **Operating Settings and Conditions**. This option is available only for the Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families ([Figure 10–18](#)).

**Figure 10–18. Operating Conditions**

19. In the **Device power characteristics** list, select **Typical** or **Maximum**. The default is **Typical**.
20. In the **Category** list, click the  icon to expand **Operating Settings and Conditions** and click **Voltage**. The **Voltage** page appears.
21. For the devices with selectable core voltage support, in the **Core supply voltage** list, select the core supply voltage for your device. This option is available for the latest devices with variable voltage selection.
22. In the **Category** list, under **Operating Settings and Conditions**, select **Temperature**. The **Temperature** page appears (Figure 10–19).

Figure 10–19. Temperature Settings Page

23. Under **Junction temperature range**, specify a junction temperature in degrees Celsius and specify the junction temperature range. Select the **Low temperature** and **High temperature** range for your selected device.
24. Specify the junction temperature and cooling solution settings. You can select **Specify junction temperature** or **Auto compute junction temperature using cooling solution**.
25. (Optional) Under **Board thermal modeling**, select the **Board thermal model** and type the **Board temperature**. This feature can only be turned on when you have selected **Auto compute junction temperature using cooling solution**.

For more information about how to use the operating condition settings, refer to [“Operating Conditions”](#) on page 10–11.

26. Click **OK** to close the **Settings** dialog box.
27. On the Processing menu, click **PowerPlay Power Analyzer Tool**. The **PowerPlay Power Analyzer Tool** dialog box appears ([Figure 10–20](#)).

**Figure 10–20. PowerPlay Power Analyzer Tool Dialog Box**

28. Click **Start** to run the PowerPlay Power Analyzer. Be sure that all the settings are correct.

You can also make changes to some of your settings in this dialog box. For example, you can click the **Add Power Input File(s)** button to make changes to your input file(s).

29. After the PowerPlay Power Analyzer runs successfully, a message appears (Figure 10–21).

**Figure 10–21. PowerPlay Power Analyzer Message**

30. Click **OK**.

31. In the **PowerPlay Power Analyzer Tool** dialog box, click **Report** to open the PowerPlay Power Analyzer Summary window. You can also view the summary in the **PowerPlay Power Analyzer Summary** page of the **Compilation Report** (Figure 10–22).

**Figure 10–22. PowerPlay Power Analyzer Summary**

## PowerPlay Power Analyzer Compilation Report

The PowerPlay Power Analyzer section of the Compilation Report is divided into the following sections.

### *Summary*

This section of the report shows your design's estimated total thermal power consumption. This includes dynamic, static, and I/O thermal power consumption. The report also includes a confidence metric that reflects the overall quality of the data sources for the signal activities.

### *Settings*

This section of the report shows your design's PowerPlay Power Analyzer settings information. This includes default input toggle rates, operating conditions, and other relevant setting information.

### *Simulation Files Read*

This section of the report lists simulation output files (VCD file or SAF) used for power estimation.

### *Operating Conditions Used*

This section of the report shows device characteristics, voltages, temperature, and cooling solution, if any, that were used during the power estimation. It also shows the entered junction temperature or auto-computed junction temperature that was used during the power analysis. This page is created only for Arria GX, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

### *Thermal Power Dissipated by Block*

This section of the report shows estimated thermal dynamic power and thermal static power consumption categorized by atoms. This information provides designers with an estimated power consumption for each atom in their design.

### *Thermal Power Dissipation by Block Type (Device Resource Type)*

This section of the report shows the estimated thermal dynamic power and thermal static power consumption categorized by block types. This information is further categorized by estimated dynamic and static power that was used, as well as providing an average toggle rate by block type. Thermal power is the power dissipated as heat from the FPGA device.

### *Thermal Power Dissipation by Hierarchy*

This section of the report shows an estimated thermal dynamic power and thermal static power consumption categorized by design hierarchy. This is further categorized by the dynamic and static power that was used by the blocks and routing within that hierarchy. This information is very useful in locating problem modules in your design.

### *Core Dynamic Thermal Power Dissipation by Clock Domain*

This section of the report shows the estimated total core dynamic power dissipation by each clock domain. This provides designs with estimated power consumption for each clock domain in their design. If the clock frequency for a domain is unspecified by a constraint, the clock frequency is listed as “unspecified.” For all the combinational logic, the clock domain is listed as no clock with 0 MHz.

### *Current Drawn from Voltage Supplies*

This section of the report lists the current that was drawn from each voltage supply. The  $V_{CCIO}$  voltage supply is further categorized by I/O bank and by voltage. The minimum safe power supply size (current supply ability) is also listed for each supply voltage. This page is created only for Arria GX, Stratix III, Stratix II, Stratix II GX, Cyclone III, Cyclone II, HardCopy II, and MAX II device families.

### *Confidence Metric Details*

The confidence metric indicates the quality of the signal toggle rate data used to compute a power estimate. The confidence metric is low if the signal toggle rate data comes from sources that are considered poor predictors of real signal toggle rates in the device during an operation. Toggle rate data that comes from simulation, or user-entered assignments on specific signals, or entities are considered reliable. Toggle rate data from default toggle rates (for example, 12.5% of the clock period) or vectorless estimation are considered relatively inaccurate. This section gives an overall confidence rating in the toggle rate data, from low to high. It also summarizes how many pins, registers, and combinational nodes obtained their toggle rates from each of simulation, user entry, vectorless estimation, or default toggle rate estimations. This detailed information can help you understand how to increase the confidence metric, letting you decide on your own confidence in the toggle rate data.

### *Signal Activities*

This section lists toggle rate and static probabilities assumed by power analysis for all signals with fan-out and pins. The signal type is provided (Pin, Registered, or Combinational), as well as the data source for the toggle rate and static probability. By default, all signal activities are reported. This may be turned off on the **PowerPlay Power Analyzer Settings** page by turning off the **Write signal activities to report file** option. Turning this option off may be advisable for a large design because of the large number of signals present. You can use the Assignment Editor to specify that activities for individual nodes or entities are reported by assigning an on value to those nodes for the Power Report Signal Activities assignment.

### *Messages*

This section lists any messages generated by the Quartus II software during the analysis.

### *Specific Rules for Reporting*

In the Stratix GX device, the XGM II State Machine block is always used together with GXB transceivers, so its power is lumped into the power for the transceivers. Therefore, the power for the XGM II State Machine block is reported as 0 Watts.

## **Scripting Support**

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp
```

The *Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

### *Running the PowerPlay Power Analyzer from the Command Line*

The separate executable that can be used to run the PowerPlay Power Analyzer is `quartus_pow`. For a complete listing of all command line options supported by `quartus_pow`, type the following at a system command prompt:

```
quartus_pow --help or quartus_sh --qhelp ↵
```

The following is an example of using the `quartus_pow` executable with project **sample.qpf**:

- To instruct the PowerPlay Power Analyzer to generate a PowerPlay Early Power Estimator file, type the following at a system command prompt:

```
quartus_pow sample --output_epe=sample.csv ↵
```

- To instruct the PowerPlay Power Analyzer to generate a PowerPlay Early Power Estimator file without doing the power estimate, type the following command at a system command prompt:

```
quartus_pow sample --output_epe=sample.csv --estimate_power=off ↵
```

- To instruct the PowerPlay Power Analyzer to use a SAF as input (**sample.saf**), type the following at a system command prompt:

```
quartus_pow sample --input_saf=sample.saf ↵
```

- To instruct the PowerPlay Power Analyzer to use two VCD files as input (**sample1.vcd** and **sample2.vcd**), perform glitch filtering on the VCD file, and use a default input I/O toggle rate of 10,000 transitions/second, type the following at a system command prompt:

```
quartus_pow sample --input_vcd=sample1.vcd  
--input_vcd=sample2.vcd --vcd_filter_glitches=on  
--default_input_io_toggle_rate=10000transitions/s ↵
```

- To instruct the PowerPlay Power Analyzer to not use any input file, a default input I/O toggle rate of 60%, no vectorless estimation, and a default toggle rate of 20% on all remaining signals, type the following at a system command prompt:

```
quartus_pow sample --no_input_file --default_input_io_toggle_rate=60%  
--use_vectorless_estimation=off --default_toggle_rate=20% ↵
```

There are no command line options to specify the information found on the **PowerPlay Power Analyzer Settings Operating Conditions** page. The easiest way to specify these options is to use the Quartus II GUI.

A report file, `<revision name>.pow.rpt`, is created by the `quartus_pow` executable and saved in the main project directory. The report file contains the same information as described in the “[PowerPlay Power Analyzer Compilation Report](#)” on page 10–39.

## Conclusion

PowerPlay power analysis tools are designed for accurate estimation of power consumption from early design concept through design implementation. Designers can use the PowerPlay Early Power Estimator to estimate power consumption during the design concept stage. Power estimations can be refined during design implementation using the Quartus II PowerPlay Power Analyzer feature. The Quartus II PowerPlay Power Analyzer produces detailed reports that you can use to optimize designs for lower power consumption and verify that the design is within your power budget.

## Document Revision History

Table 10–5 shows the revision history for this chapter.

<b>Date and Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	<ul style="list-style-type: none"> <li>Updated Figures 10–4, 10–9, 10–10, 10–11, and 10–22.</li> <li>Updated “Generating a SAF or VCD File Using the Quartus II Simulator” on page 10–24.</li> <li>Updated “Generating a VCD File Using a Third-Party Simulator” on page 10–28.</li> </ul>	Updated for the Quartus II software version 7.2.
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>Updated procedures for “Generating a SAF or VCD File Using the Quartus II Simulator” on page 10–24.</li> <li>Updated figures.</li> <li>Added “Document Revision History” on page 10–45.</li> </ul>	Added support for Arria GX devices.
March 2007 v7.0.0	Added Cyclone III to list of devices supported (page 10-2)	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>Updated “Generating a SAF or VCD File Using the Quartus II Simulator” by changing steps in certain processes to accommodate new functionality.</li> <li>Updated “Operating Conditions” by adding Selectable Core Voltage option.</li> <li>Updated Figure 10-2, 10-9, 10-10, 10-12, 10-14, 10-18, and 10-19.</li> </ul>	Figure changes were made to accommodate the changes to the GUI. Also, added information for Stratix III devices.
May 2006 v6.0.0	Chapter title changed to <i>PowerPlay Power Analysis</i> . Updated for the Quartus II software version 6.0.0: <ul style="list-style-type: none"> <li>Added information about the EPE tools.</li> <li>Added information about the power analyzer.</li> </ul>	—
October 2005 v5.1.0	Updated for the Quartus II software version 5.1.	—

As FPGA usage expands into more high-speed applications, signal integrity becomes an increasingly important factor to consider for an FPGA design.

Signal integrity issues must be taken into account as part of FPGA I/O planning and assignments, as well as in the design and layout of the printed circuit board (PCB) that must support the FPGA. Early design simulation is essential for preventing issues that may require a board redesign. The Quartus II software provides a number of features that will help you make smart board design decisions to ensure good signal integrity on all your high-speed interfaces.

This section includes the following chapter:

- [Chapter 11, Signal Integrity Analysis with Third-Party Tools](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

As FPGA devices are used in more high-speed applications, signal integrity and timing margin between the FPGA and other devices on the printed circuit board (PCB) become increasingly important considerations to ensure proper system operation. To avoid time consuming redesigns and expensive board respins, the topology and routing of critical signals must be simulated. The high-speed interfaces available on current FPGA devices must be modeled accurately and integrated into timing models and board-level signal integrity simulations. To do this, the tools used in the design of an FPGA and its integration into a PCB must be “board-aware,” able to take into account properties of the board routing as well as the connected devices on the board.

The Quartus® II software provides a number of methodologies, resources, and tools to assist in ensuring good signal integrity and timing margin between an Altera® FPGA device and other components on the board. Three types of analysis are possible with the Quartus II software:

- I/O timing with a default or user-specified capacitive load and no signal integrity analysis (default)
- The Quartus II Advanced I/O Timing option utilizing a user-defined board trace model to produce enhanced timing reports from accurate “board-aware” simulation models
- Full board routing simulation in third-party tools using Altera provided or generated IBIS or HSPICE I/O models

I/O timing using a specified capacitive test load requires no special configuration other than setting the size of the load. I/O timing reports from Quartus II TimeQuest or the Quartus II Classic Timing Analyzer are generated based only on point-to-point delays within the I/O buffer and assume the presence of the capacitive test load with no other details about the board specified. The default size of the load is based on the I/O standard selected for the pin. Timing is measured to the FPGA pin with no signal integrity analysis details.

The Advanced I/O Timing option expands the details in I/O timing reports by taking board topology and termination components into account. A complete point-to-point board trace model is defined and accounted for in the timing analysis. This ability to define a board trace model is an example of how the Quartus II software is “board-aware.”

In this case, timing and signal integrity metrics between the I/O buffer and the defined far end load are analyzed and reported in enhanced reports generated by the Quartus II TimeQuest Timing Analyzer.

For more information about defining capacitive test loads or how to use the Advanced I/O Timing option to configure a board trace model, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

This chapter focuses on the third type of analysis. The Quartus II software can export accurate HSPICE models with the built-in HSPICE Writer. You can run signal integrity simulations with these complete HSPICE models in Synopsys HSPICE. Input/Output Buffer Information Specification (IBIS) models of the FPGA I/O buffers are also created easily with the Quartus II IBIS Writer. You can integrate IBIS models into any third-party simulation tool that supports them, such as Mentor Graphics Hyperlynx software. With the ability to create industry-standard model definition files quickly, you can build accurate simulations that can provide data to help improve board-level signal integrity.

This chapter describes some of the basics of board-level signal integrity and why it should be taken into consideration as part of the general FPGA design flow. You will see that it is easy to produce accurate I/O models in the Quartus II software that take into account the unique properties of timing and signal integrity found in FPGA devices. You will learn how to add these models to your board routing simulations in the most widely used third-party simulation tools. Finally, you will find out where to go for more information about board-level signal integrity and how the Quartus II software and Altera FPGA devices fit into an overall high-speed system design.

This chapter is intended for FPGA and board designers. FPGA designers will learn about the concepts and steps involved in getting their designs simulated and how to adjust their designs to improve board-level timing and signal integrity. Board designers will learn how to get accurate models from the Quartus II software and how to use those models in their simulation software. To get the most out of this chapter, you should be familiar with the use of the Quartus II software. It is also helpful if you are familiar with some of the basic concepts involved in signal integrity and the design techniques and components required to have good signal integrity on a PCB. Finally, you should know how to set up simulations and use your selected third-party simulation tool. This chapter gives a basic overview of how to use the output from the IBIS Writer and HSPICE Writer in these tools, but it does not provide detailed instructions on their use.

For information about basic signal integrity concepts and signal integrity details pertaining to Altera FPGA devices, refer to the [Altera Signal Integrity Center](#).

## The Need for FPGA to Board Signal Integrity Analysis

When creating an FPGA design, the designer usually focuses on the FPGA logic design and functionality. A main focus for the design of the PCB to support the FPGA is to make sure FPGA I/O assignments match the correct pads and routing to ensure the FPGA signals are correctly connected to the rest of the circuit. In the past, this was all that was necessary to ensure proper operation. However, FPGA devices can now be configured with a wide assortment of high-speed interfaces that communicate with many other devices on the board.

With the introduction of high-speed interfaces to traditional FPGA design, it becomes necessary to make sure that timing and signal integrity margins between the FPGA and other devices on the board are within specification and tolerance before a single PCB is built. If the board trace is designed poorly or the route is too heavily loaded, noise in the signal can cause data corruption, while overshoot and undershoot can potentially damage input buffers over time if allowed to continue.

The use of the I/O model creation and analysis tools available in the Quartus II software early in the design process can help prevent problems before a costly board respin is needed. In general, creating and running accurate simulations is difficult and time consuming. The tools in the Quartus II software help by automating the I/O model setup and creation process by configuring the models specifically for your design. You will be able to set up and run accurate simulations quickly and acquire data that helps guide your FPGA and board design, using either the Advanced I/O Timing feature for analysis in the Quartus II software environment or the output from the IBIS and HSPICE Writers in third-party simulation tools.

The discussion of signal integrity in this chapter refers to board-level signal integrity based on I/O buffer configuration and board parameters, not simultaneous switching noise (SSN), also known as ground bounce or  $V_{CC}$  sag. SSN is a product of multiple output drivers switching at the same time, causing an overall drop in the voltage of the chip's power supply. This can cause temporary glitches in the specified level of ground or  $V_{CC}$  for the device. For a more thorough discussion of SSN and ways to prevent it, refer to application note AN 315: *Guidelines for Designing High-Speed FPGA PCBs*.

# The Double Counting Problem for FPGA Output Timing

Simulating I/Os using accurate models is extremely helpful for finding and fixing FPGA I/O timing and board signal integrity issues before any boards are built. However, the usefulness of such simulations is directly related to the accuracy of the models used and whether the simulations are set up and performed correctly. To ensure accuracy in models and simulations created for FPGA output signals, the timing hand-off between  $t_{CO}$  timing in the Quartus II software and simulation-based board delay must be taken into account. If this hand-off is not handled correctly, the calculated delay could either count some of the delay twice or even miss counting some of the delay entirely.

## Defining the Double Counting Problem

The double counting problem is inherent to the way output timing is analyzed versus the method used for HSPICE models. The timing analyzer tools in the Quartus II software measure delay timing for an output signal from the core logic of the FPGA design through the output buffer ending at the FPGA pin with a default capacitive load or a specified value for the selected I/O standard. This measurement is the  $t_{CO}$  timing variable as shown in Figure 11-1.

Figure 11-1. Double Counting Problem

HSPICE models for board simulation measure  $t_{PD}$  (propagation delay) from an arbitrary reference point in the output buffer, through the device pin, out along the board routing, and ending at the signal destination (the red bar in [Figure 11-1](#)).

It is immediately apparent that if these two delays were simply added together, the delay between the output buffer and the device pin would be counted twice in the calculation (the black bar in [Figure 11-1](#)). A model or simulation that does not account for this double count would create overly pessimistic simulation results, since the double counted delay can artificially limit I/O performance. To fix the problem, it may seem like simply subtracting the overlap between  $t_{CO}$  and  $t_{PD}$  would account for the double count. However, this adjustment would not be accurate because each measurement is based on a different load.

Input signals do not exhibit this problem because the HSPICE models for inputs stop at the FPGA pin instead of at the input buffer. In this case, simply adding the delays together produces an accurate measurement of delay timing.

### The Solution to Double Counting

To adjust the measurements to account for the double counting, the delay between the arbitrary point in the output buffer selected by the HSPICE model and the FPGA pin must be subtracted from either  $t_{CO}$  or  $t_{PD}$  before adding the results together. The subtracted delay must also be based on a common load between the two measurements. This is done by repeating the HSPICE model measurement but with the same load used by the Quartus II software for the  $t_{CO}$  measurement. This second measurement, called  $t_{TESTLOAD}$ , is illustrated with the top circuit in [Figure 11-2](#).

**Figure 11–2. Common Test Loads Used for Output Timing**

With  $t_{TESTLOAD}$  known, the total delay for the output signal from the FPGA logic to the signal destination on the board, accounting for the double count, is calculated as shown in [Equation 1](#).

$$(1) \quad t_{\text{delay}} = t_{CO} + (t_{PD} - t_{TESTLOAD})$$

The preconfigured simulation files generated by the HSPICE Writer in the Quartus II software are designed to automatically account for the double counting problem based on this calculation. This makes it easy to perform accurate timing simulations without the need to manually make adjustments for double counting.

## I/O Model Selection: IBIS or HSPICE

The Quartus II software can export two different types of I/O models that are useful for different simulation situations. IBIS models define the behavior of input or output buffers through the use of voltage-current (V-I) and voltage-time (V-t) data tables. HSPICE models, often referred to as HSPICE decks, include complete physical descriptions of the transistors and parasitic capacitances that make up an I/O buffer along with all the parameter settings needed to run a simulation. The HSPICE decks generated by the Quartus II software are preconfigured with the I/O standard, voltage, and pin loading settings for each pin in your design.

The choice of I/O model type is based on a number of factors. [Table 11-1](#) provides a more detailed comparison of the two I/O model types as well as information and examples of situations about where and when they might be used.

**Table 11-1. IBIS and HSPICE Model Comparison**

Feature	IBIS Model	HSPICE Model
I/O Buffer Description	<b>Behavioral</b> —I/O buffers are described by voltage-current and voltage-time tables in typical, minimum, and maximum supply voltage cases.	<b>Physical</b> —I/O buffers and all components in a circuit are described by their physical properties, such as transistor characteristics and parasitic capacitances, as well as their connections to one another.
Model Customization	<b>Simple and limited</b> —The model completely describes the I/O buffer and does not usually need to be customized.	<b>Fully customizable</b> —Unless connected to an arbitrary board description, the description of the board trace model must be customized in the model file. All parameters of the simulation are also adjustable.
Simulation Set Up and Run Time	<b>Fast</b> —Simulations run quickly once set up correctly.	<b>Slow</b> —Simulations take time to set up and take longer to run and complete.
Simulation Accuracy	<b>Good</b> —For most simulations, accuracy is sufficient to make useful adjustments to the FPGA and/or board design to improve signal integrity.	<b>Excellent</b> —Simulations are highly accurate, making HSPICE simulation almost a requirement for any high-speed design where signal integrity and timing margins are tight.
Third-Party Tool Support	<b>Excellent</b> —Almost all third-party board simulation tools support IBIS.	<b>Good</b> —Most third-party tools that support SPICE support HSPICE. However, Synopsys HSPICE is required for simulations of Altera's encrypted HSPICE models.

For more information about IBIS files created by the Quartus II IBIS Writer and IBIS files in general, as well as links to websites with detailed information, refer to *AN 283: Simulating Altera Devices with IBIS Models*. For more information about HSPICE model files created by the Quartus II HSPICE Writer, refer to *AN 424: I/O Simulations Using HSPICE*.

## FPGA to Board Signal Integrity Analysis Flow

Board signal integrity analysis can take place at any point in the FPGA design process and is often performed both before and after board layout. If it is performed early in the process as part of a pre-PCB layout analysis, the models used for simulations can be more generic and can be changed as much as needed to see how adjustments improve timing or signal integrity and help with the design and routing of the PCB. Simulations and the resulting changes made at this stage allow you to analyze “what if” scenarios to better plan and implement your design. To assist with early board signal integrity analysis, you can download generic IBIS model files for each device family from the Altera website. If board signal integrity analysis is performed late in the design, it is typically used for a post-layout verification. The inputs and outputs of the FPGA are defined, and required board routing topologies and constraints are known. Simulations can help you find problems that may still exist in the FPGA or board design before fabrication and assembly. In either case, a simple process flow illustrates how to create accurate IBIS and HSPICE models from a design in the Quartus II software and transfer them to third-party simulation tools. [Figure 11-3](#) shows this flow.

This chapter is organized around the type of model, IBIS or HSPICE, that you use for your simulations. Once you understand the steps in the analysis flow, refer to the section of this chapter that corresponds to the model type you are using.

Figure 11–3. Third-Party Board Signal Integrity Analysis Flow

## Create I/O and Board Trace Model Assignments

If your design uses a Stratix II device, you can configure a board trace model for output signals or for bidirectional signals in output mode and automatically transfer its description to HSPICE decks generated by the HSPICE Writer. This helps improve simulation accuracy. To do this, turn on the **Enable Advanced I/O Timing** option in the **TimeQuest Timing Analyzer** page in the **Settings** dialog box and configure the board trace model assignment settings for each I/O standard used in your design. You can add series or parallel termination, specify the transmission line length, and set the value of the far-end capacitive load. You can configure these parameters in either the Board Trace Model view in the Pin Planner or by clicking **Device and Pin Options** in the **Device** page of the **Settings** dialog box.

For information about how to use Advanced I/O Timing and configure board trace models for the I/O standards used in your design, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

The Quartus II software can generate IBIS models and HSPICE decks without the need to configure a board trace model with the Advanced I/O Timing option. In fact, IBIS models ignore any board trace model settings other than the far-end capacitive load. If any load value is set other than the default, the delay given by IBIS models generated by the IBIS Writer cannot be used to account correctly for the double counting problem. The load value mismatch between the IBIS delay and the  $t_{CO}$  measurement of the Quartus II software prevents the delays from being safely added together. Warning messages displayed when the EDA Netlist Writer runs indicate when this mismatch occurs.

## Enable Output File Generation

IBIS and HSPICE model files are not generated by the Quartus II software by default. To generate or update the files automatically during each project compilation, select the type of file to generate and a location where to save the file in the project settings. These settings can also be specified with commands in a Tcl script.

## Generate the Output Files

The IBIS and HSPICE Writers in the Quartus II software are run as part of the EDA Netlist Writer during normal project compilation. If either writer is turned on in the project settings, IBIS or HSPICE files are created and stored in the specified location. For IBIS, a single file is generated containing information about all assigned pins, while HSPICE file generation creates separate files for each assigned pin. You can run the EDA Netlist Writer separately from a full compilation in the Quartus II

software or at the command line. However, you must fully compile the project or perform I/O Assignment Analysis at least once for the IBIS and HSPICE Writers to have information about the I/O assignments and settings in the design.

## Customize the Output Files

The files generated by either the IBIS or HSPICE Writer are text files that you can edit and customize easily for design or experimentation purposes. IBIS files downloaded from the Altera website must be customized with the correct RLC values for the specific device package you have selected for your design. IBIS files generated by the IBIS Writer do not require this customization since they are automatically configured with the RLC values for your selected device. HSPICE decks require modification to include a detailed description of your board. With **Enable Advanced I/O Timing** turned on and a board trace model defined in the Quartus II software, generated HSPICE decks automatically include that model's parameters. However, it is recommended that you replace that model with a more detailed model that more accurately describes your board design. A default simulation included in the generated HSPICE decks measures delay between the FPGA and the far-end device. You can make additions or adjustments to the default simulation in the generated files to change the parameters of the default simulation or to perform additional measurements.

## Set Up and Run Simulations in Third-Party Tools

Once you have generated the files, you can use them to perform simulations in your selected simulation tool. With IBIS models, you can apply them to input, output, or bidirectional buffer entities and quickly set up and run simulations. For HSPICE decks, the simulation parameters are included in the files. Open the files in Synopsys HSPICE and run simulations for each pin as needed. With HSPICE decks generated from the HSPICE Writer, the double counting problem is accounted for, ensuring that your simulations are accurate. Simulations that involve IBIS models created with anything other than the default loading settings in the Quartus II software must take the change in the size of the load between the IBIS delay and the Quartus II  $t_{CO}$  measurement into account. Warning messages during compilation alert you to this change.

## Interpret Simulation Results

After running your simulations, you may find timing or signal integrity issues with your high-speed signals. Based on your simulation results, you can make adjustments to I/O assignment settings in the Quartus II software, such as drive strength or I/O standard, or make changes to your board routing or topology. After regenerating models in the Quartus II software based on the changes you have made, rerun the simulations to see if your changes corrected the problem.

## Simulation with IBIS Models

IBIS models provide a way to run accurate signal integrity simulations quickly. IBIS models describe the behavior of I/O buffers with voltage-current and voltage-time data curves. Because of their behavioral nature, IBIS models do not have to include any information about the internal circuit design of the I/O buffer. Most component manufacturers, including Altera, provide IBIS models for free download and use in signal integrity analysis simulation tools. You can download generic device family IBIS models from the Altera website for early design simulation or use the IBIS Writer to create custom IBIS models for your existing design.

## Elements of an IBIS Model

An IBIS model file (`.ibs`) is a text file that describes the behavior of an I/O buffer across minimum, typical, and maximum temperature and voltage ranges with a specified test load. The tables and values specified in the IBIS file describe five basic elements of the I/O buffer. [Figure 11-4](#) highlights each of these elements in the I/O buffer model.

**Figure 11-4. Five Basic Elements in IBIS Models**

The following elements correspond to each numbered block in Figure 11–4.

1. **Pulldown**—A voltage-current table describes the current when the buffer is driven low based on a pull-down voltage range of  $-V_{CC}$  to  $2V_{CC}$ .
2. **Pullup**—A voltage-current table describes the current when the buffer is driven high based on a pull-up voltage range of  $-V_{CC}$  to  $V_{CC}$ .
3. **Ground and Power Clamps**—Voltage-current tables describe the current when clamping diodes for electrostatic discharge (ESD) are present. The ground clamp voltage range is  $-V_{CC}$  to  $V_{CC}$ , and the power clamp voltage range is  $-V_{CC}$  to ground.
4. **Ramp and Rising/Falling Waveform**—A voltage-time ( $dv/dt$ ) ratio describes the rise and fall time of the buffer during a logic transition. Optional rising and falling waveform tables can be added to more accurately describe the characteristics of the rising and falling transitions.
5. **Total Output Capacitance and Package RLC**—The total output capacitance includes the parasitic capacitances of the output pad, clamp diodes (if present), and input transistors. The package RLC is device package-specific and defines the resistance, inductance, and capacitance of the bond wire and pin of the I/O.

For more information about IBIS models and Altera-specific features, including links to the official IBIS specification, refer to AN 283: *Simulating Altera Devices with IBIS Models*.

## Creating Accurate IBIS Models

There are two ways to obtain Altera device IBIS files for your board-level signal integrity simulations. You can download generic IBIS models from the Altera website or you can use the IBIS writer in the Quartus II software to create design-specific models.

### *Download IBIS Models*

Altera provides IBIS models for almost all FPGA and FPGA configuration devices. Check the Download Center at [www.altera.com](http://www.altera.com) to see if models for your selected device are available. You can use the IBIS models from the website to perform early simulations of the I/O buffers you expect to use in your design as part of a pre-layout analysis.

Downloaded IBIS models have the RLC package values set to one particular device in each device family. To accurately simulate your design with the model, you must adjust the RLC values in the IBIS model file to match the values for your particular device package by performing the following steps:

1. Download and expand the ZIP file (.zip) of the IBIS model for the device family you are using for your design. The .zip file contains the IBIS model file along with an IBIS model user guide and a model data correlation report.
2. Download the Package RLC Values spreadsheet for the same device family.
3. Open the spreadsheet and locate the row that describes the device package used in your design.
4. Copy the minimum, maximum, and typical values of resistance, inductance, and capacitance for your device package from the package's **I/O** row.
5. Open the IBIS model file in a text editor and locate the [Package] section of the file.
6. Overwrite the listed values copied with the values from the spreadsheet and save the file.

The IBIS model file is now customized for your device package and can be used for any simulation. IBIS models downloaded and used for simulations in this manner are generic. They describe only a certain set of models listed for each device on the IBIS model Download Center page on the Altera website. To create customized models for your design, use the IBIS Writer as described in the next section.

### *Generate Custom IBIS Models with the IBIS Writer*

If you have started your FPGA design and have created custom I/O assignments, such as drive strength settings or the enabling of clamping diodes for ESD protection, you can use the Quartus II IBIS Writer to create custom IBIS models to more accurately reflect your assignments. IBIS models created with the IBIS Writer take I/O assignment settings into account.

If the **Enable Advanced I/O Timing** option is turned off, the generated IBIS model files are based on the load value setting for each I/O standard on the **Capacitive Loading** tab of the **Device and Pin Options** dialog box in the **Device** page of the **Settings** dialog box. With the **Enable Advanced**

**I/O Timing** option turned on, IBIS models use an effective capacitive load based on settings found in the board trace model on the **Board Trace Model** tab in the **Device and Pin Options** dialog box or the Board Trace Model view in the Pin Planner. The effective capacitive load is based on the sum of the **Near capacitance**, **Transmission line distributed capacitance**, and the **Far capacitance** settings in the board trace model. Resistances and transmission line inductance values are ignored.

If any changes are made from the default load settings, the delay in the generated IBIS model cannot safely be added to the Quartus II  $t_{CO}$  measurement to account for the double counting problem. This is because the load values between the two delay measurements do not match. When this happens, the Quartus II software displays warning messages when the EDA Netlist Writer runs to remind you about the load value mismatch.

When the IBIS Writer is enabled, it generates a custom IBIS model file whenever the EDA Netlist Writer is run in the Quartus II software. To turn on the IBIS Writer and create custom IBIS model files, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. In the **Category** list, click the  icon to expand **EDA Tool Settings** and select **Board-Level**.
3. Under **Board-Level Signal Integrity Analysis Format**, in the **Format** list, select **IBIS** (Figure 11-5).

Figure 11–5. Enabling IBIS Model Generation in the Settings Dialog Box

4. IBIS models are stored in the *<project directory>/board/ibis* directory by default. To change the directory, click the browse button next to the **Output directory** box, and browse to the desired location.
5. Click **OK** to close the **Settings** dialog box.
6. If the project has not been compiled, run a full compilation to create a netlist and establish I/O assignments. On the Processing menu, click **Start Compilation**. The IBIS model file, named *<project name>.ibs*, is saved in the specified location.
7. If the project has been compiled before, you only need to run the EDA Netlist Writer to create or update the IBIS model file. On the Processing menu, point to Start and click **Start EDA Netlist Writer**. The IBIS model file is created or updated in the specified location.

You can save compilation time when creating the IBIS model file the first time for early design simulation by performing only required steps of the compilation process instead of a full compilation of your project. Run Analysis and Synthesis and I/O Assignment Analysis before creating the IBIS model file with the EDA Netlist Writer.

For more information about IBIS model generation, refer to the AN 283: *Simulating Altera Devices with IBIS Models* application note or the Quartus II Help.

## Design Simulation Using the Mentor Graphics HyperLynx Software

You must integrate IBIS models downloaded from the Altera website or created with the Quartus II IBIS Writer into board design simulations to accurately model timing and signal integrity. The HyperLynx software from Mentor Graphics is one of the most popular tools for design simulation. HyperLynx software makes it easy to integrate IBIS models into simulations.

The HyperLynx software is a PCB analysis and simulation tool for high-speed designs, consisting of two products, LineSim and BoardSim. LineSim is an early simulation tool. Before any board routing takes place, LineSim is used to simulate “what if” scenarios to assist in creating routing rules and defining board parameters. BoardSim is a post-layout tool used to analyze existing board routing. Specific nets are selected from a board layout file and simulated in a manner similar to LineSim. With board and routing parameters, and surrounding signal routing known, highly accurate simulations of the final fabricated PCB are possible. This section focuses on LineSim. Since the process of creating and running simulations is very similar for both LineSim and BoardSim, the details of IBIS model use in LineSim applies to simulations in BoardSim.

Simulations in LineSim are configured using a schematic GUI to create connections and topologies between I/O buffers, route trace segments, and termination components. LineSim provides two methods, cell-based and free-form, for creating routing schematics. Cell-based schematics are based on fixed cells consisting of typical placements of buffers, trace impedances, and components. Parts of the grid-based cells are filled with the desired objects to create the topology. A topology in a cell-based schematic is limited by the available connections within and between the cells.

A more robust and expandable way to create a circuit schematic for simulation is to use the free-form schematic format in LineSim as shown in Figure 11–6. The free-form schematic format makes it easy to place parts into any configuration and edit them as needed. This section describes the use of IBIS models with free-form schematics, but the process is nearly identical for cell-based schematics.

Figure 11–6. HyperLynx LineSim Free-Form Schematic Editor

When you use HyperLynx software to perform simulations, you typically perform the following steps:

1. Create a new LineSim free-form schematic document and set up the board stackup for your PCB using the Stackup Editor. In this editor, you specify board layer properties including layer thickness, dielectric constant, and trace width.
2. Create a circuit schematic for the net you want to simulate. The schematic represents all the parts of the routed net including source and destination I/O buffers, termination components, transmission line segments, and representations of impedance discontinuities such as vias or connectors.
3. Assign IBIS models to the source and destination I/O buffers to represent their behavior during operation.
4. Attach probes from the digital oscilloscope that is built in to LineSim to points in the circuit that you want to monitor during simulation. Typically, at least one probe is attached to the pin of a destination I/O buffer. For differential signals, you can attach a differential probe to both the positive and negative pins at the destination.
5. Configure and run the simulation. You can simulate a rising or falling edge and test the circuit under different drive strength conditions.
6. Interpret the results and make adjustments. Based on the waveforms captured in the digital oscilloscope, you can adjust anything in the circuit schematic to correct any signal integrity issues, such as overshoot or ringing. If necessary, you can make I/O assignment changes in the Quartus II software, regenerate the IBIS file with the IBIS Writer, and apply the updated IBIS model to the buffers in your HyperLynx software schematic.
7. Repeat the simulations and circuit adjustments until you are satisfied with the results. Once the operation of the net meets your design requirements, implement changes to your I/O assignments in the Quartus II software and/or adjust your board routing constraints, component values, and placement to match the simulation.

For more information about HyperLynx software, including schematic creation, simulation setup, model usage, product support, licensing, and training, refer to HyperLynx Help or the Mentor Graphics website at [www.mentor.com](http://www.mentor.com).

## Configuring LineSim to Use Altera IBIS Models

You must configure LineSim to find and use the downloaded or generated IBIS models for your design. To do this, you add the location of your IBIS model file(s) to the LineSim Model Library search path. Then you apply a selected model to a buffer in your schematic.

To add the Quartus II software's default IBIS model location, *<project directory>/board/ibis*, to the HyperLynx LineSim model library search path, perform the following steps in LineSim:

1. From the Options menu, click **Directories**. The **Set Directories** dialog box appears (Figure 11–7). The Model-library file path(s) list displays the order in which LineSim searches file directories for model files.

**Figure 11–7. LineSim Set Directories Dialog Box**

2. Click **Edit**. A dialog box appears where you can add directories and adjust the order in which LineSim searches them (Figure 11–8).

Figure 11–8. LineSim Select Directories Dialog Box

3. Click **Add** and browse to the default IBIS model location, *<project directory>/board/ibis*. Click **OK**.
4. Click **Up** to move the IBIS model directory to the top of the list, and click **Generate Model Index** to update LineSim’s model database with the models found in the added directory.
5. Click **OK**. The IBIS model directory for your project is added to the top of the Model-library file path(s) list. Click **OK** to close the Set Directories dialog box.

### Integrating Altera IBIS Models into LineSim Simulations

Once the location for IBIS files is set, you can assign the downloaded or generated IBIS models to the buffers in your schematic. To do this, perform the following steps:

1. Double-click a buffer symbol in your schematic to open the **Assign Models** dialog box (Figure 11–9). You can also click **Assign Models** from the buffer symbol’s right-click menu.

Figure 11–9. LineSim Assign Model Dialog Box

2. The pin of the buffer symbol you selected should be highlighted in the **Pins** list. If you want to assign a model to a different symbol or pin, select it from the list.
3. Click **Select**. The **Select IC Model** dialog box appears (Figure 11–10).

Figure 11–10. LineSim Select IC Model Dialog Box

4. To filter the list of available libraries to display only IBIS models, select **.IBS**. Scroll through the **Libraries** list, and click the name of the library for your design. By default, this is *<project name>.ibs*.
5. The device for your design should be selected as the only item in the **Devices** list. If not, select your device from the list.
6. From the **Signal** list, select the name of the signal you want to simulate. You can also choose to select by device pin number.
7. Click **OK**. The **Assign Models** dialog box displays the selected IBIS model file and signal.
8. If applicable to the signal you chose, adjust the buffer settings as needed for the simulation.
9. Select and configure other buffer pins from the **Pins** list in the same manner. Click **OK** when all I/O models are assigned.

## Running and Interpreting LineSim Simulations

You can now run any desired simulations and make adjustments to the I/O assignments or simulation parameters as needed. For example, if after running a simulation you see too much overshoot in the simulated signal at the destination buffer as seen in [Figure 11–11](#), you could adjust the drive strength I/O assignment setting to a lower value. Regenerate the IBIS model file, and run the simulation again to verify if the change fixed the problem.

**Figure 11–11. Example of Overshoot in HyperLynx with IBIS Models**

If you see a discontinuity or other anomalies at the destination, such as slow rise and fall times as shown in [Figure 11–12](#), adjust the termination scheme or termination component values. After making these changes, rerun the simulation to check whether your adjustments solved the problem. In this case, it is not necessary to regenerate the IBIS model file.

**Figure 11–12. Example of Signal Integrity Anomaly in HyperLynx with IBIS Models**

For more information about board-level signal integrity and to learn about ways to improve it with simple changes to your design, visit the Altera Signal Integrity Center at [www.altera.com](http://www.altera.com).

## Simulation with HSPICE Models

HSPICE decks are used to perform highly accurate simulations by precisely describing the physical properties of all aspects of a circuit. HSPICE decks describe I/O buffers, board components, and all the connections between them, as well as defining the parameters of the simulation to be run. By their nature, HSPICE decks are highly customizable and require a detailed description of the circuit under simulation to be effective. For Stratix II devices, when **Enable Advanced I/O Timing** is turned on, the HSPICE decks generated by the Quartus II HSPICE Writer automatically include board components and topology defined in the Board Trace Model that you configure in the Pin Planner or in the **Board Trace Model** tab of the **Device and Pin Options** dialog box. All HSPICE decks generated by the Quartus II software include compensation for the double count problem (for more information about the double count problem, refer to “[The Double Counting Problem for FPGA Output Timing](#)” on page 11–4). You can simulate with the default simulation parameters built in to the generated HSPICE decks or make adjustments to customize your simulation.

For more detailed information about the HSPICE model files created by the Quartus II HSPICE Writer, refer to *AN 424: I/O Simulations Using HSPICE*.

## Supported Devices and Signaling

The HSPICE Writer in the Quartus II software version 6.1 supports the devices and signaling defined in [Table 11–2](#). Only Stratix II devices support the creation of a board trace model in the Quartus II software for automatic inclusion in an HSPICE deck. Other devices require the board description to be manually added to the HSPICE file.

Device	Input	Output	Single-Ended	Differential	Automatic Board Trace Model Description
Stratix® II	✓	✓	✓	✓	✓
Stratix II GX (non-HSSI signals)	✓	✓	✓	✓	—
HardCopy® II	✓	✓	✓	✓	—

If you are using a Stratix II device for your design, you can turn on **Enable Advanced I/O Timing** and configure the board trace model for each I/O standard used in your design. The HSPICE files will include the board trace description you create in the Board Trace Model view in the Pin Planner or the **Board Trace Model** tab in **Device and Pin Options** dialog box.

For more information about Advanced I/O Timing and configuring board trace models for the I/O standards in your design, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

## Creating Accurate HSPICE Models

The HSPICE Writer must be turned on before HSPICE model files are created. HSPICE models are not generated by default in the Quartus II software. When enabled, the HSPICE Writer operates as part of the EDA Netlist Writer in the compilation process. When a project is fully compiled or the EDA Netlist Writer is run, the HSPICE Writer generates or updates the HSPICE model files.

### Creating HSPICE Model Files Using the Quartus II GUI

To turn on the HSPICE Writer and create HSPICE deck files for each pin in your design, perform the following steps:

1. On the Assignments menu, click **Settings**.
2. In the **Category** list, click the  icon to expand **EDA Tool Settings** and select **Board-Level**.
3. Under **Board-Level Signal Integrity Analysis Format**, in the **Format** list, select **HSPICE** (Figure 11–13).

**Figure 11–13. Enabling HSPICE Deck and Model Generation in the Settings Dialog Box**

4. HSPICE decks are stored in the *<project directory>/board/hspice* directory by default. To change the directory, click the browse button next to the **Output directory** box, and browse to the desired location.
5. Click **OK** to close the **Settings** dialog box.
6. If the project has not been compiled, run a full compilation to create a netlist and establish I/O assignments. On the Processing menu, click **Start Compilation**. HSPICE decks for each assigned pin, along with required model library subdirectories, are saved in the specified location.
7. If the project has been compiled, you only need to run the EDA Netlist Writer to create or update the HSPICE deck and model files. On the Processing menu, point to Start and click **Start EDA Netlist Writer**. The HSPICE decks and models are created or updated in the specified location.

You can save compilation time when creating HSPICE decks the first time for early design simulation by performing only required steps of the compilation process instead of a full compilation of your project. Run Analysis and Synthesis and I/O Assignment Analysis before creating the HSPICE deck files with the EDA Netlist Writer.

Preconfigured HSPICE simulation files generated by the HSPICE Writer are named *<device pin #>\_<signal name>\_<in|out>.sp*. Both an “in” and an “out” file are generated for bidirectional pins. HSPICE files are text files and can be edited with any ASCII text editor.

Two folders, named lib and cir, are also generated. These folders contain the encrypted I/O buffer descriptions and other information needed for running simulations. If you want to move the HSPICE model files to a different location, be sure to move these folders as well. The HSPICE model files include direct references to files in the lib and cir folders. If they are not in the same location, your HSPICE simulations will not run.

### *Creating HSPICE Model Files Using Tcl Scripting and the Command Line*

If you use a script-based flow to compile your project, you can turn on the creation of HSPICE model files by including the following commands in your Tcl script (.tcl file):

```
set_global_assignment -name EDA_BOARD_DESIGN_SIGNAL_INTEGRITY_TOOL "HSPICE (Signal Integrity)"
set_global_assignment -name EDA_OUTPUT_DATA_FORMAT HSPICE -section_id eda_board_design_signal_integrity
```

```
set_global_assignment -name EDA_NETLIST_WRITER_OUTPUT_DIR <output_directory> -
section_id eda_board_design_signal_integrity
```

The *<output\_directory>* option specifies the location where HSPICE model files are saved. By default, the following directory is used:

```
<project_directory>/board/hspice
```

You can run the HSPICE Writer at a command prompt by running the EDA Netlist Writer with the following command:

```
quartus_eda.exe <project name> --board_signal_integrity=on --format=HSPICE --
output_directory=<output_directory>
```

The *<project name>* should match the name of the Quartus II Settings File (**.qsf**) for your project.

## Customizing HSPICE Model Files

HSPICE models generated by the HSPICE Writer can be used for simulation as generated. A default board description is included, and a default simulation is set up to measure rise and fall delays for both input and output simulations which compensates for the double counting problem. However, Altera recommends that you customize the board description to more accurately represent your routing and termination scheme. To do this, open the generated HSPICE model files for all pins you want to simulate, and locate the following commented section:

```
* //////////////////////////////////////
* I/O Board Trace and Termination Description
* - Replace this with your board trace and termination description
* //////////////////////////////////////
```

Replace the board description in this section with a description of your board or the board topology you would like to simulate in each HSPICE file.

For input simulations, you must include a description of the device that provides the stimulus for the signal. Locate the following comments that indicate where to place the stimulus device description in the file:

```
* //////////////////////////////////////
* Sample source stimulus placeholder
* - Replace this with your I/O driver model
* //////////////////////////////////////
```

For more information about configuring and customizing HSPICE model files for simulation, refer to the HSPICE manual.

## Design Simulation Using Synopsys HSPICE

Synopsys HSPICE is an industry standard SPICE simulation tool; it is required for running SPICE simulation with Altera's encrypted HSPICE models. While you can use HSPICE model files in other tools, such as Mentor Graphics HyperLynx software, Synopsys HSPICE is still required to decrypt the models. You can use Synopsys HSPICE along with the included Avancestry viewer to run simulations and view the results as waveforms.

For more information about Synopsys HSPICE, including licensing, installation, usage, support, and training, refer to the HSPICE manual or the Synopsys website at [www.synopsys.com](http://www.synopsys.com).

## Running HSPICE Simulations

Since simulation parameters are configured directly in the HSPICE model files, running a simulation requires only that you open an HSPICE file in the HSPICE User Interface (hspui) and start the simulation. The hspui window is shown in Figure 11–14.

Figure 11–14. HSPICE hspui Window

Click **Open** and browse to the location of the HSPICE model files generated by the Quartus II HSPICE Writer. The default location for HSPICE model files is *<project directory>/board/hspice*. Select the **.sp** file, generated by the HSPICE Writer, for the signal you want to simulate and click **OK**.

Click **Simulate** to run the simulation. The status of the simulation is displayed in the window and saved in a **.lis** file with the same name as the **.sp** file when the simulation is complete. Check the **.lis** file if an error occurs during the simulation requiring a change in the **.sp** file to fix.

## Viewing and Interpreting Tabular Simulation Results

The `.lis` file stores the collected simulation data in tabular form. The default simulation configured by the HSPICE Writer produces delay measurements for rising and falling transitions on both input and output simulations. These measurements are found in the `.lis` file and named `tpd_rise` and `tpd_fall`. For output simulations, these values are already adjusted for the double count. Add either of these measurements to the Quartus II  $t_{CO}$  delay to determine the complete delay from the FPGA logic to the load pin. For input simulations, add either of these measurements to the Quartus II  $t_{SU}$  and  $t_H$  delay values to calculate the complete delay from the far end stimulus to the FPGA logic. Other values found in the `.lis` file, such as `tpd_uncomp_rise`, `tpd_uncomp_fall`, `t_dblcnt_rise`, and `t_dblcnt_fall`, are parts of the double count compensation calculation. These values are not needed for further analysis.

## Viewing Graphical Simulation Results

You can quickly view the results of the simulation as a graphical waveform display using the Avanwaves viewer included with HSPICE. With the default simulation configured by the HSPICE Writer, you can view the simulated waveforms at both the source and destination in input and output simulations.

To see the waveforms for the simulation, in the HSPICE `hspui` window, click **Avanwaves**. The Avanwaves viewer opens and displays the Results Browser as shown in [Figure 11-15](#).

**Figure 11–15. HSPICE Avanwaves Results Browser**

The Results Browser lets you quickly select which waveform to view in the main viewing window. If multiple simulations are run on the same signal, the list at the top of the Results Browser displays the results of each simulation. Click the simulation description to select which simulation to view. By default, the descriptions are derived from the first line of the HSPICE file, so the description may appear as a line of asterisks.

Select the type of waveform to view. With the default simulation, select **Voltages** from the **Types** list to see the source and destination waveforms. On the **Curves** list, double-click the waveform you want to view. The waveform appears in the main viewing window. You can zoom in and out and adjust the view as desired (Figure 11–16).

**Figure 11–16. Avanwaves Waveform Viewer**

### Making Design Adjustments Based on HSPICE Simulations

Based on the results of your simulations, you can make adjustments to the I/O assignments or simulation parameters if required. For example, after you run a simulation and see overshoot or ringing in the simulated signal at the destination buffer as shown in the example in [Figure 11–17](#), you can adjust the drive strength I/O assignment setting to a lower value. Regenerate the HSPICE deck, and run the simulation again to verify that the change fixed the problem.

**Figure 11–17. Example of Overshoot in the Avanwaves Waveform Viewer**

If there is a discontinuity or any other anomalies at the destination as shown in the example in [Figure 11–18](#), adjust the board description in the Quartus II Board Trace Model (for Stratix II devices) or in the generated HSPICE model files to change the termination scheme or adjust termination component values. After making these changes, regenerate the HSPICE files, if necessary, and rerun the simulation to verify whether your adjustments solved the problem.

Figure 11–18. Example of Signal Integrity Anomaly in the Avanwaves Waveform Viewer

For more information about board-level signal integrity and to learn about ways to improve it with simple changes to your FPGA design, refer to the Altera Signal Integrity Center.

## Conclusion

As FPGA devices are used in more high-speed applications, it becomes increasingly necessary to perform board-level signal integrity analysis simulations. You must run such simulations to ensure good signal integrity between the FPGA and any connected devices. The Quartus II software helps to simplify this process with the ability to automatically generate I/O buffer description models easily with the IBIS and HSPICE Writers. IBIS models can be integrated into a third party signal integrity analysis workflow using a tool such as Mentor Graphics HyperLynx software, generating quick and accurate simulation results. HSPICE decks include preconfigured simulations and only require descriptions of board routing and stimulus models to create highly accurate simulation

results using Synopsys HSPICE. Either type of simulation helps prevent unnecessary board spins, increasing your productivity and decreasing your costs.

## Referenced Documents

This chapter references the following documents:

- *AN 424: I/O Simulations Using HSPICE*
- *I/O Management* chapter in volume 2 of the *Quartus II Handbook*

## Document Revision History

Table 11–3 shows the revision history for this chapter.

<i>Table 11–3. Document Revision History</i>		
<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 11–36.	—
May 2007 v7.1.0	Added Referenced Documents.	—
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only. No other changes made to chapter.	—
November 2006 v6.1.0	Initial Release	—

Debugging today's FPGA designs can be a daunting task. As your product requirements continue to increase in complexity, the time you spend on design verification continues to rise. To get your product to market as quickly as possible, you must minimize design verification time. To help alleviate the time-to-market pressure, you need a set of verification tools that are powerful, yet easy to use.

The Quartus® II software SignalTap® II Logic Analyzer and the SignalProbe™ features analyze internal device nodes and I/O pins while operating in-system and at system speeds. The SignalTap II Logic Analyzer uses an embedded logic analyzer to route the signal data through the JTAG port to either the SignalTap II Logic Analyzer or an external logic analyzer or oscilloscope. The SignalProbe feature uses incremental routing on unused device routing resources to route selected signals to an external logic analyzer or oscilloscope. A third Quartus II software feature, the Chip Editor, can be used in conjunction with the SignalTap II and SignalProbe debugging tools to speed up design verification and incrementally fix bugs uncovered during design verification. This section explains how to use each of these features.

This section includes the following chapters:

- [Chapter 12, Quick Design Debugging Using SignalProbe](#)
- [Chapter 13, Design Debugging Using the SignalTap II Embedded Logic Analyzer](#)
- [Chapter 14, In-System Debugging Using External Logic Analyzers](#)
- [Chapter 15, In-System Updating of Memory and Constants](#)
- [Chapter 16, Design Debugging Using In-System Sources and Probes](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## 12. Quick Design Debugging Using SignalProbe

Q1153008-7.2.0

### Introduction

Hardware verification can be a lengthy and expensive process. The SignalProbe incremental routing feature helps reduce the hardware verification process and time-to-market for system-on-a-programmable-chip (SOC) designs.

Easy access to internal device signals is important in design or debugging. The SignalProbe feature makes design verification more efficient by quickly routing internal signals to I/O pins without affecting the design. Starting with a fully routed design, you can select and route signals for debugging to either previously reserved or currently unused I/O pins.

You can use the SignalProbe feature with the Stratix® series, Cyclone® series, MAX® II, and APEX™ series device families.

This chapter is divided into two sections. If you are using the SignalProbe feature to debug your Stratix series, Cyclone series, and MAX II device, then refer to [“Debugging Using the SignalProbe Feature” on page 12–4](#). If you are using the SignalProbe feature to debug your APEX series device, refer to [“Using SignalProbe with the APEX Device Family” on page 12–19](#).

## On-Chip Debugging Tool Comparison

The Quartus® II software provides a number of different ways to help debug your FPGA design after programming the device. The SignalTap® II Logic Analyzer, SignalProbe, and the Logic Analyzer Interface (LAI) share some similar features, but each has advantages. In some debugging situations, it can be difficult to decide which tool is best to use or whether multiple tools are required. Table 12–1 compares common debugging features between these tools and provides suggestions for which is the best tool to use for a given feature.

Note that “✓” indicates the suggested best tool for the feature, “—” indicates that while the tool is available for that feature, that tool may not give the best results, and “N/A” indicates that the feature is not applicable for the selected tool.

**Table 12–1. Suggested On-Chip Debugging Tools for Common Debugging Features Note (1) (Part 1 of 2)**

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Embedded Analyzer	Description
Large Sample Depth	N/A	✓	—	An external logic analyzer used with the LAI has a bigger buffer to store more captured data than the SignalTap II Logic Analyzer. No data is captured or stored with SignalProbe.
Ease in Debugging Timing Issue	N/A	✓	—	An external logic analyzer used with the LAI provides you with access to timing mode, enabling you to debug combined streams of data.
Minimal Effect on Logic Design	✓	✓(2)	✓(2)	SignalProbe incrementally routes nodes to pins, not affecting the design at all. The LAI adds minimal logic to a design, requiring fewer device resources. The SignalTap II Logic Analyzer has little effect on the design when it is set as a separate design partition using incremental compilation.
Short Compile and Recompile Time	✓	✓(2)	✓(2)	SignalProbe attaches incrementally routed signals to previously reserved pins, requiring very little recompilation time to make changes to source signal selections. The SignalTap II Logic Analyzer and the LAI can take advantage of incremental compilation to refit their own design partitions to decrease recompilation time.

**Table 12–1. Suggested On-Chip Debugging Tools for Common Debugging Features *Note (1)* (Part 2 of 2)**

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Embedded Analyzer	Description
<b>Triggering Capability</b>	N/A	✓	—	Although advanced triggering is available in the SignalTap II Logic Analyzer, many additional triggering options are only available on an external logic analyzer when used with the LAI.
<b>I/O Usage</b>	—	—	✓	No additional output pins are required with the SignalTap II Logic Analyzer. Both the LAI and SignalProbe require I/O pin assignments.
<b>Acquisition Speed</b>	N/A	—	✓	The SignalTap II Logic Analyzer can acquire data at speeds of over 200 MHz. The same acquisition speeds are obtainable with an external logic analyzer used with the LAI, but signal integrity issues may limit this.
<b>No JTAG Connection Required</b>	✓	—	—	An FPGA design with the SignalTap II Logic Analyzer or the LAI requires an active JTAG connection to a host running the Quartus II software. SignalProbe does not require a host for debugging purposes.
<b>External Equipment</b>	—	—	✓	The SignalTap II Logic Analyzer logic is completely internal to the programmed FPGA device. No extra equipment is required other than a JTAG connection from a host running the Quartus II software or the stand-alone SignalTap II software. SignalProbe and the LAI require the use of external debugging equipment, such as multimeters, oscilloscopes, or logic analyzers.

**Notes to Table 12–1:**

- (1) ✓ indicates the suggested best tool for the feature.  
 — indicates that while the tool is available for that feature, that tool may not give the best results.  
 N/A indicates that the feature is not applicable for the selected tool.
- (2) When used with incremental compilation.

## Debugging Using the SignalProbe Feature

The SignalProbe feature enables you to reserve available pins and route internal signals to those reserved pins, while preserving the behavior of your design. SignalProbe is an effective debugging tool providing visibility into your FPGA.

This section describes the SignalProbe process for the Stratix series, Cyclone series, and MAX II device families. Using SignalProbe with APEX devices is described in [“Using SignalProbe with the APEX Device Family” on page 12–19](#). APEX devices do not support post-fit netlist changes made as engineering change orders (ECOs).

You can reserve pins for SignalProbe and assign I/O standards before or after a full compilation. Each SignalProbe source to SignalProbe pin connection is implemented as an ECO change that is applied to your netlist after a full compilation.

To route the internal signals to the device’s reserved pins for SignalProbe, perform the following tasks:

1. Reserve the SignalProbe Pins, described on [page 12–4](#).
2. Perform a Full Compilation, described on [page 12–6](#).
3. Assign a SignalProbe Source, described on [page 12–6](#).
4. Add Registers to the Pipeline Path to SignalProbe Pin, described on [page 12–7](#).
5. Perform a SignalProbe Compilation, described on [page 12–9](#).
6. Analyze the Results of the SignalProbe Compilation, described on [page 12–10](#).
7. Generate the Programming File, described on [page 12–11](#).

### Reserve the SignalProbe Pins

You can reserve SignalProbe pins before or after compiling your design. Reserving SignalProbe pins before a compilation is optional. You can also reserve any unused I/Os of the device for SignalProbe pins after compilation. You can assign sources easily after reserving your SignalProbe pins. The sources for SignalProbe pins are the internal nodes and registers in the post-compilation netlist that you want to probe.

Although you can reserve SignalProbe pins using many features within the Quartus II software, including the Pin Planner and the Tcl interface, you should use the **SignalProbe Pins** dialog box to create and edit your SignalProbe pins.

To reserve an available package pin as a SignalProbe pin using the **SignalProbe Pins** dialog box, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears (Figure 12–1). The SignalProbe pin name and I/O standard appear as the only fields that are editable if a place and route, or fit, has not been performed.

**Figure 12–1. Reserving a SignalProbe Pin in the SignalProbe Pins Dialog Box**

2. In the **Current and potential SignalProbe pins** list, click on a pin from the **Number** column and type your SignalProbe pin name into the **Pin name** box.
3. Select an I/O standard from the **I/O standard** drop-down list.

4. Click **Add** to add the new SignalProbe pin or **Change** if you are editing a previously reserved pin for SignalProbe. (Figure 12–1 shows the dialog box editing a previously reserved pin; if you were adding a new SignalProbe pin, the **Add** button appears instead of the **Change** button.)
5. Click **OK**.

## Perform a Full Compilation

You must complete a full compilation to generate an internal netlist containing a list of internal nodes to probe to a SignalProbe output.

To perform a full compilation, on the processing menu, click **Start Compilation**.

## Assign a SignalProbe Source

A SignalProbe source can be any combinational node, register, or pin in your post-compilation netlist. To find a SignalProbe source, use the SignalProbe filter in the Node Finder to filter out all sources that cannot be probed. You may not be able to find a particular internal node because the node may be optimized away during synthesis, or the node cannot be routed to the SignalProbe pin, as it is untappable. For example, internal nodes and registers within the Gigabit transceivers can not be probed because there are no physical routes to the pins available.

To probe virtual I/O pins generated in low-level partitions in an incremental compilation flow, select the source of the logic that feeds the Virtual Pin as your SignalProbe source pin.

To assign a SignalProbe source to your SignalProbe reserved pin, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears (Figure 12–1 on page 12–5).
2. If a SignalProbe reserved pin is shown, click on the pin in the **Current and potential SignalProbe pins** list. Alternately, you can click on an available pin number in the **Current and potential SignalProbe pins** list and type a new SignalProbe pin name into the **Pin name** box.
3. In the **Source** box, specify the source name. Click the browse button. The **Node Finder** dialog box appears.

4. When you open the **Node Finder** dialog box from the **SignalProbe Pins** dialog box, **SignalProbe** is selected by default in the **Filter** list. Click **List** to show a set of nodes that can be probed in the **Nodes Found** list.
5. Select your source node in the **Nodes Found** list and click the “>” button. The selected node appears in the **Selected Nodes** list.
6. Click **OK**.
7. After a source is selected, the **SignalProbe enable** option is turned on. Click **Change** or **Add** to accept the changes.

Because SignalProbe pins are implemented and routed as ECOs, turning the **SignalProbe enable** option on or off is the same as selecting **Apply Selected Change** or **Restore Selected Change** in the Change Manager window. (If the Change Manager window is not visible at the bottom of your screen, from the View menu, point to **Utility Windows** and click **Change Manager**.)

For more information about the Change Manager for the Chip Planner and Resource Property Editor, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

## Add Registers to the Pipeline Path to SignalProbe Pin

You can specify the number of registers placed between a SignalProbe source and a SignalProbe pin to synchronize the data with a clock and to control the latency of the SignalProbe outputs. The SignalProbe feature automatically inserts the number of registers specified into the SignalProbe path.

Figure 12–2 shows a single register between the SignalProbe source `Reg_b_1` and SignalProbe `SignalProbe_Output_2` output pin added to synchronize the data between the two SignalProbe output pins.

When you add a register to a SignalProbe pin, the SignalProbe compilation attempts to place the register to best fit timing requirements. You can place SignalProbe registers near the SignalProbe source to meet  $f_{MAX}$  requirements, or you can place the register near the I/O to meet  $t_{CO}$  requirements.

**Figure 12–2. Synchronizing SignalProbe Outputs with a SignalProbe Register**

To pipeline an existing SignalProbe, perform the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears.
2. Select a SignalProbe pin and in the **Clock** box, type the clock name used to drive your registers, or click the browse button to use the Node Finder to select your clock source.
3. In the **Registers** box, specify the number of registers you want to add in between the SignalProbe source and the SignalProbe output.
4. Click **Change**.
5. Click **OK**.

In addition to the clock input for the pipeline registers, you can also specify a reset signal pin for the pipeline registers. To specify a reset pin for the pipeline registers, use the Tcl command `make_sp` as described in [“Scripting Support” on page 12–17](#).

## Perform a SignalProbe Compilation

Perform a SignalProbe compilation to route your SignalProbe pins. On the Processing menu, point to Start and click **Start SignalProbe Compilation** (Figure 12-3). A SignalProbe compilation saves and checks all netlist changes without recompiling the other parts of the design, and completes compilation in a fraction of the time of a full compilation. The design's current placement and routing are preserved.

**Figure 12-3. Performing the SignalProbe Compilation**

## Analyze the Results of the SignalProbe Compilation

After a SignalProbe compilation, you can view the results in the compilation report file. Each SignalProbe pin is displayed in the SignalProbe Fitting Result page in the Fitter section of the Compilation Report (Figure 12–4). To view the status of each SignalProbe pin in the SignalProbe Pins dialog box, click SignalProbe Pins on the Tools menu.

Figure 12–4. SignalProbe Fitting Results Page in the Compilation Report Window

You can also view the status of each SignalProbe pin the Change Manager window (Figure 12–5). (If the Change Manager window is not visible at the bottom of your GUI, from the View menu, point to Utility Windows and click Change Manager.)

Figure 12–5. Change Manager Window with SignalProbe Pins

For more information about how to use the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

To view the timing results of each successfully routed SignalProbe pin, on the Processing menu, point to Start and click **Start Timing Analysis**.

## Generate the Programming File

After a SignalProbe compilation, generate the new programming file containing your successfully routed SignalProbe pins. To generate a programming file, on the Processing menu, point to Start and click **Start Assembler**.

## SignalProbe ECO flows

Beginning with the Quartus II software version 6.0, SignalProbe pins are implemented using the same flow as other post-compilation changes made as ECOs. The following section describes SignalProbe ECO flows with and without the Quartus II incremental compilation feature.

### *SignalProbe ECO Flow with Quartus II Incremental Compilation*

Beginning with the Quartus II software version 6.1, the incremental compilation feature is turned on by default. The top-level design is automatically set to a design partition when the incremental compilation feature is on. A design partition during incremental compilation can have different netlist types. (Netlist types can be set to source HDL, post synthesis, or post-fit.) The netlist type indicates whether that partition should be resynthesized or refit during Quartus II incremental compilation. Incremental compilation saves you time and preserves the placement of unchanged partitions in your design if small changes must be made to some partitions late in the design cycle.

For more information about the Quartus II incremental compilation feature, refer to the *Quartus Incremental Compilation Feature for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

The behavior of SignalProbe pins during an incremental compilation depends on the Netlist Type setting. If the top-level partition netlist type is set to post-fit, SignalProbe ECOs are retained when you recompile the design.

If some SignalProbe sources from lower-level partitions are set to a netlist type other than post-fit, then during re-compilation the Quartus II fitter uses the post-fit netlist type for those partitions as well, and a warning message appears in the message window.

All of the partitions containing SignalProbe ECOs are linked together and must use the post-fit netlist type. The same rule applies when your top-level partition is set to post-synthesis and one of the lower-level partitions' netlist type is set to post-fit. When you recompile your design, the Quartus II fitter uses the post-fit netlist for the top-level partition and SignalProbe ECOs are retained.

The behavior is different in the case that your top-level partition netlist type is set to post-synthesis and you have no other lower-level partitions defined, or the lower-level partition netlist types are also set to post-synthesis. If you create SignalProbe ECOs and re-compile the design, your SignalProbe ECOs are not retained and a warning message appears in the messages window. The warning indicates that ECO modifications are discarded; however, all of the ECO information is retained in the Change Manager. In this case, you can apply SignalProbe ECOs from the Change Manager and perform the **Check and Save All Netlist Changes** step as described in [“SignalProbe ECO Flow without Quartus Incremental Compilation”](#) on page 12-12.

#### *SignalProbe ECO Flow without Quartus Incremental Compilation*

If you do not use the Quartus II incremental compilation feature and you implement SignalProbe pins after the initial compilation of your design, then SignalProbe ECOs are not retained during recompilation. However, all of the SignalProbe ECOs remain in the Change Manager.

To apply a SignalProbe ECO, right-click the Change Manager and select **Apply Selected Change** ([Figure 12-6](#)). (If the Change Manager window is not visible at the bottom of your screen, from the View menu, point to **Utility Windows** and click **Change Manager**.)

**Figure 12–6. Applying SignalProbe ECOs**

Alternately, you can use the **SignalProbe Pins** dialog box to enable the ECOs (Figure 12–7). This has the same effect as applying the SignalProbe ECOs within the Change Manager.

**Figure 12–7. Enabling ECOs in the SignalProbe Pins Dialog Box**

After applying the selected SignalProbe ECO, you can either click **Check and Save All Netlist Changes** from the menu within the Change Manager (Figure 12–8) or from Processing menu, point to Start and click **Start Check and Save All Netlist Changes** to perform the ECO compilation.

**Figure 12–8. Check and Save All Netlist Changes**

## Common Questions About the SignalProbe Feature

The following are answers to common questions about the SignalProbe feature.

### *Why Did I Get the Following Error Message, “Error: There are No Enabled SignalProbes to Process”?*

This error message is generated when a SignalProbe compilation was attempted with either no SignalProbe pins to route, or with all SignalProbe pins disabled.

This may occur if you perform a SignalProbe compilation after a full compilation. For example, when a full compilation is performed, all SignalProbe pins are disabled. You can create or re-enable your SignalProbe pins in the **SignalProbe Pins** dialog box.

### *How Can I Retain My SignalProbe ECOs during Re-compilation of My Design?*

To retain your existing ECOs during recompilation of your design, you must use Quartus II incremental compilation. To learn more about the flow, refer to [“SignalProbe ECO Flow with Quartus II Incremental Compilation”](#) on page 12–11.

### *Why Did My SignalProbe Source Disappear in the Change Manager?*

The SignalProbe source information for each SignalProbe is stored in the project database (**db** directory). SignalProbe pins are post-compilation changes to your netlist and are interpreted as ECOs. These changes are stored in the project **db** and if the project database is removed, the SignalProbe source information is lost and will not appear in the

**SignalProbe Pins** dialog box. To restore your SignalProbe pins after the design compilation step, source the `signalprobe_qlsf.tcl` script located in your project directory.

You can restore your SignalProbe source information by typing the following command from a command prompt:

```
quartus_cdb -t signalprobe_qlsf.tcl
```

After the compilation with Quartus II software, you must close your design project before typing the above command. Once the command finishes, you can open your design project again and the change manager shows the sources for SignalProbe pins.

### *What is an ECO and Where Can I Find More Information on ECO?*

ECOs are late design cycle changes made to your design that do not alter functionality and timing. For more information about ECO and using the Change Manager, refer to the *Engineering Change Management with the Chip Planner* chapter in volume 2 of the *Quartus II Handbook*.

### *How Do I Migrate My Previous SignalProbe Assignments in the Quartus II Software Versions 5.1 and below to Versions 6.0 and Higher?*

In earlier versions of the Quartus II software, SignalProbe pins were stored in the Quartus II Settings File (`.qlsf`). These assignments are automatically converted into ECO changes when you open the **SignalProbe** dialog box or when you start a SignalProbe compilation in the Quartus II software versions 6.0 and higher.

For example, the SignalProbe source assignment from a Quartus II Settings File is removed and added to the Change Manager as an ECO after the **SignalProbe** dialog box is opened, or when you perform a SignalProbe compilation.

---

#### **Example 12–1. SignalProbe Assignments in the Quartus II Settings File**

```
set_location_assignment PIN_C22 -to my_signalprobe_pin
set_instance_assignment -name RESERVE_PIN "AS SIGNALPROBE OUTPUT" -to my_signalprobe_pin
set_instance_assignment -name IO_STANDARD LVTTTL -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_ENABLE ON -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_SOURCE inst5[0] -to my_signalprobe_pi
```

---

**Example 12–2. SignalProbe Assignments in the Quartus II Settings File after Opening the SignalProbe Pins Dialog Box**

```
set_location_assignment PIN_C22 -to my_signalprobe_pin
set_instance_assignment -name RESERVE_PIN "AS SIGNALPROBE OUTPUT" -to my_signalprobe_pin
set_instance_assignment -name IO_STANDARD LVTTTL -to my_signalprobe_pin
set_instance_assignment -name SIGNALPROBE_ENABLE ON -to my_signalprobe_pin
```

---

*What are all the Changes for the SignalProbe Feature between the Quartus II Software Version 5.1 and Earlier, and Version 6.0 and Later?*

The following list of changes affect users of the SignalProbe feature in the Quartus II software versions 5.1 and below with Stratix series, Cyclone series, and MAX II device families.

- In Quartus II software versions 5.1 and earlier, the **SignalProbe Pins** dialog box was accessed on the Assignments menu. To access it with the Quartus II software version 6.0 and later, on the Tools menu, click **SignalProbe Pins**.
- A full compilation is required before making SignalProbe connections. However, you can still reserve pins before compilation for later use by SignalProbe. You can reserve pins by creating a SignalProbe in the **SignalProbe** dialog box without specifying a source. This is the same behavior as in the Quartus II software version 5.1.
- To route the SignalProbe pins, you must perform a SignalProbe compilation after a full compilation. The **Automatically route SignalProbe signals during compilations** and **Modify latest fitting results during SignalProbe compilation** options are no longer supported.
- After subsequent compiles, full or incremental, existing SignalProbe pins are disabled and are not present in the post-compilation netlist. To add them back, enable the SignalProbe pins and perform a SignalProbe compilation.
- SignalProbe pins are not controlled via assignments in the Quartus II Settings File because they are now ECOs. Existing Quartus II Settings Files automatically convert to ECOs when a SignalProbe compilation is performed or when the **SignalProbe** dialog box is opened.
- The Tcl interface for creating SignalProbe pins has improved and is a part of the Chip Planner package `::quartus::chip_editor`. Refer to [“Scripting Support” on page 12–17](#).
- Previously, the `quartus_fit --signalprobe` command was used to perform a SignalProbe compilation. This is not supported in the Quartus II software version 6.0 and later, and is replaced by the improved Tcl interface and the `check_netlist_and_save` Tcl command.

- The SignalProbe timing report generated after a successful SignalProbe compilation is not available in the Quartus II software version 6.0 and later. You can view the timing results of your SignalProbe pins in the SignalProbe Fitting Results, under the Fitter report, or in the  $t_{CO}$  results page of the Timing report.
- You can not make SignalProbe pins in the Assignment Editor. Use the **SignalProbe Pins** dialog box to make and edit your SignalProbe pins.

## Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

### *Make a SignalProbe Pin*

You can make a SignalProbe pin by typing the following command:

```
make_sp [-h | -help] [-long_help] [-clk <clk>] [-io_std <io_std>] \
-loc <loc> -pin_name <pin name> [-regs <regs>] [-reset <reset>] \
-src_name <source name> ↵
```

### *Delete a SignalProbe Pin*

You can delete a SignalProbe pin by typing the following command:

```
delete_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

### *Enable a SignalProbe Pin*

You can enable a SignalProbe pin by typing the following command:

```
enable_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

### *Disable a SignalProbe Pin*

You can disable a SignalProbe pin by typing the following command:

```
disable_sp [-h | -help] [-long_help] -pin_name <pin name> ↵
```

### *Perform a SignalProbe Compilation*

You can perform a SignalProbe compilation by typing the following command:

```
check_netlist_and_save ↵
```

### *Migrating Previous SignalProbe Pins to the Quartus II Software Versions 6.0 and Later*

You can migrate previous SignalProbe pins to the Quartus II software versions 6.0 and later by typing the following command:

```
convert_signal_probes ↵
```

### *Script Example*

[Example 12-3](#) is a script that creates a SignalProbe pin called `sp1` and connecting it to source node `reg1` in a project that was already compiled.

---

#### **Example 12-3. Creating a SignalProbe Pin Called `sp1`**

```
Package require ::quartus::chip_editor
Project_open project
Read_netlist
Make_sp -pin_name sp1 -src_name reg1
Check_netlist_and_save
Project_close
```

---

## Using SignalProbe with the APEX Device Family

APEX devices do not support post-fit netlist changes made as ECOs. You can use SignalProbe compilation to route internal signals to output pins incrementally. The SignalProbe incremental routing feature does not affect design behavior.

To use the SignalProbe feature, follow these steps:

1. Reserve SignalProbe pins. For more information, refer to “[Reserve the SignalProbe Pins](#)” on page 12–4.
2. Assign a SignalProbe source to each SignalProbe pin.
3. Perform a SignalProbe compilation.
4. Analyze the results of a SignalProbe compilation.

### Adding SignalProbe Sources

A SignalProbe source is a signal in the post-compilation design database with a possible route to an output pin. You can assign a SignalProbe source to a SignalProbe pin, or an unused output pin by performing the following steps:

1. On the Tools menu, click **SignalProbe Pins**. The **SignalProbe Pins** dialog box appears.
2. In the **Current and potential SignalProbe pins** list, select the SignalProbe pin to which you want to add a SignalProbe source.
3. Click **Browse** and select a SignalProbe source.
4. Click **OK**.

The **Node Finder** dialog box displays with the SignalProbe filter selected ([Figure 12–9](#)). Click **List** to view all of the available SignalProbe sources. If you cannot find a specific node with the

SignalProbe filter, then the node either has either been removed by the Quartus II software during optimization, or placed in the device where there are no possible routes to a pin.

**Figure 12–9. Available SignalProbe Sources in the Node Finder**

- In the **Assign SignalProbe Pins** dialog box, click **Add** if a source has not been assigned to the SignalProbe pin.

or

Click **Change** for a SignalProbe pin that has a source already assigned.

When the source of the SignalProbe pin is added or changed, the SignalProbe pin is automatically enabled. To disable a SignalProbe pin, turn off **SignalProbe enable**.

- Click **OK**.

## Performing a SignalProbe Compilation

You can start a SignalProbe compilation manually or automatically after a full compilation. A SignalProbe compilation includes the following:

- Validates SignalProbe pins.
- Validates your specified SignalProbe sources.
- If applicable, adds registers into SignalProbe paths.
- Attempts to route from SignalProbe sources through registers to SignalProbe pins.

To run the SignalProbe compilation automatically after a full compilation, on the Tools menu, click **SignalProbe Pins**. In the **SignalProbe Pins** dialog box, turn on **Automatically route SignalProbe signals during compilation**.

To run a SignalProbe compilation manually after a full compilation, on the Processing menu, point to Start and click **Start SignalProbe Compilation**.

You must run the Fitter before a SignalProbe compilation. The Fitter generates a list of all internal nodes that can be used as SignalProbe sources.

You can enable and disable each SignalProbe pin by turning the **SignalProbe enable** option on and off in the **SignalProbe Pins** dialog box.

### *Running SignalProbe with Smart Compilation*

Optimally, you can run a smart compilation, which reduces compilation time by running only necessary modules during compilation. However, a full compilation is required if any design files, Analysis and Synthesis settings, or Fitter settings have changed.

To turn on smart compilation, on the Assignments menu, click **Settings**. In the **Category** list, select **Compilation Process Settings** and turn on **Use Smart compilation**.

If you run a SignalProbe compilation with smart compilation turned on, and there are changes to a design file or settings related to the Analysis and Synthesis or Fitter modules, the following message is displayed:

```
Error: Can't perform SignalProbe compilation because design requires a full compilation.
```

You should turn smart compilation on, which allows you to work with the latest settings and design files.

## **Understanding the Results of a SignalProbe Compilation**

After a SignalProbe compilation, the results appear in two sections of the compilation report file. The fitting results and status ([Table 12-2](#)) of each SignalProbe pin is displayed in the SignalProbe Fitting Result page in the Fitter section of the compilation report ([Figure 12-10](#)).

The timing results of each successfully routed SignalProbe pin is displayed in the **SignalProbe source to output delays** page in the Timing Analysis section of the compilation report ([Figure 12-11](#)).

After a SignalProbe compilation, the processing page of the Messages window also provides the results of each SignalProbe pin and displays slack information for each successfully routed SignalProbe pin.

**Table 12–2. Status Values**

Status	Description
Routed	Connected and routed successfully
Not Routed	Not enabled
Failed to Route	Failed routing during last SignalProbe compilation
Need to Compile	Assignment changed since last SignalProbe compilation

**Figure 12–10. SignalProbe Fitting Results Page in the Compilation Report Window**

**Figure 12–11. SignalProbe Source to Output Delays Page in the Compilation Report Window**

### Analyzing SignalProbe Routing Failures

The SignalProbe can begin compilation; however, one of the following reasons can prevent complete compilation:

- **Route unavailable**—the SignalProbe compilation failed to find a route from the SignalProbe source to the SignalProbe pin because of routing congestion
- **Invalid or nonexistent SignalProbe source**—you entered a SignalProbe source that does not exist or is invalid
- **Unusable output pin**—the output pin selected is found to be unusable

Routing failures can occur if the SignalProbe pin's I/O standard conflicts with other I/O standards in the same I/O bank.

If routing congestion prevents a successful SignalProbe compilation, you can allow the compiler to modify the routing to the specified SignalProbe source. On the Tools menu, click **SignalProbe Pins** and turn on **Modify latest fitting results during SignalProbe compilation**. This setting allows the Fitter to modify existing routing channels used by your design.

Turning on **Modify latest fitting results during SignalProbe compilation** can change the performance of your design.

### SignalProbe Scripting Support for APEX Devices

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ←
```

The *Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information about all settings and constraints in the Quartus II software. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## Reserving SignalProbe Pins

Use the following Tcl commands to reserve a SignalProbe pin.

```
set_location_assignment <location> -to <SignalProbe pin name>

set_instance_assignment -name RESERVE_PIN \
"AS SIGNALPROBE OUTPUT" -to <SignalProbe pin name> ←
```

Valid locations are pin location names, such as Pin\_A3.

For more information about reserving SignalProbe pins, refer to [“Reserve the SignalProbe Pins” on page 12–4](#).

## Adding SignalProbe Sources

Use the following Tcl commands to add SignalProbe sources. For more information about adding SignalProbe sources, refer to [“Adding SignalProbe Sources” on page 12–19](#). The following command assigns the node name to a SignalProbe pin:

```
set_instance_assignment -name SIGNALPROBE_SOURCE \
<node name> -to <SignalProbe pin name> ←
```

The next command turns on the SignalProbe routing. You can turn off individual SignalProbe pins by specifying OFF instead of ON with the following command:

```
set_instance_assignment -name SIGNALPROBE_ENABLE ON \
-to <SignalProbe pin name> ←
```

## Assigning I/O Standards

Use the following Tcl command to assign an I/O standard to a pin:

```
set_instance_assignment -name IO_STANDARD \
<I/O standard> -to <SignalProbe pin name> ←
```

For a list of valid I/O standards, refer to the I/O Standards general description in the Quartus II Help.

## Adding Registers for Pipelining

Use the following Tcl commands to add registers for pipelining:

```
set_instance_assignment -name SIGNALPROBE_CLOCK \
<clock name> -to <SignalProbe pin name>
```

```
set_instance_assignment \
-name SIGNALPROBE_NUM_REGISTERS <number of registers> \
-to <SignalProbe pin name> ←
```

## Run SignalProbe Automatically

Use the following Tcl command to run SignalProbe automatically after a full compile.

```
set_global_assignment -name \
SIGNALPROBE_DURING_NORMAL_COMPILATION ON
```

For more information about running SignalProbe automatically, refer to [“Performing a SignalProbe Compilation” on page 12–20](#).

## Run SignalProbe Manually

You can run SignalProbe manually with a Tcl command or the `quartus_fit` command at a command prompt.

```
execute_flow -signalprobe ←
```

The `execute_flow` command is in the flow package. At a command prompt, type the following command:

```
quartus_fit <project name> --signalprobe ←
```

For more information about running SignalProbe manually, refer to [“Performing a SignalProbe Compilation” on page 12–20](#).

## Enable or Disable All SignalProbe Routing

Use the Tcl command in [Example 12–4](#) to turn on or turn off SignalProbe routing. In the `set_instance_assignment` command, specify `ON` to turn on SignalProbe routing or `OFF` to turn off SignalProbe routing.

---

### Example 12–4. Turning SignalProbe On or Off with Tcl

```
set spe [get_all_assignments -name SIGNALPROBE_ENABLE] \
foreach_in_collection asgn $spe {
    set signalprobe_pin_name [lindex $asgn 2]
    set_instance_assignment -name SIGNALPROBE_ENABLE -to \
$signalprobe_pin_name <ON|OFF> } ←
```

---

For more information about enabling or disabling SignalProbe routing, refer to [page 12–20](#).

## Running SignalProbe with Smart Compilation

Use the following Tcl command to turn on **Smart Compilation**:

```
set_global_assignment -name SMART_RECOMPILE ON ←
```

For more information, refer to “[Running SignalProbe with Smart Compilation](#)” on page 12–21.

## Allow SignalProbe to Modify Fitting Results

Use the following Tcl command to turn on **Modify latest fitting results**.

```
set_global_assignment -name \
SIGNALPROBE_ALLOW_OVERUSE ON ←
```

For more information, refer to “[Analyzing SignalProbe Routing Failures](#)” on page 12–23.

## Conclusion

Using the SignalProbe feature can significantly reduce the time required compared to a full recompilation. You can use the SignalProbe feature to get quick access to internal design signals to perform system-level debugging.

# Document Revision History

Table 12–3 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 12–26.	—
May 2007 v7.1.0	Added Referenced Documents, minor updates to address ADoQS issues.	—
March 2007 v7.0.0	Updated Quartus II software 7.0 revision and date only. No other changes made to chapter.	—
November 2006 v6.1.0	Updated for the Quartus II software version 6.1.0: <ul style="list-style-type: none"> <li>• New section (SignalProbe ECO flows) added to explain how SignalProbe pins’ ECOs are affected during Quartus II Incremental Compilation.</li> <li>• QandA added to answer: How Can I Retain My SignalProbe ECOs during Re-compilation of My Design.</li> </ul>	Quartus II software version 6.1.0 added more ECO features; the chapter updated to reflect this change.
May 2006 v6.0.0	Updated for the Quartus II software version 6.0.0: <ul style="list-style-type: none"> <li>• Documented new SignalTap features.</li> </ul>	—
December 2005 v5.1.1	Added SMART_RECOMPILE assignment.	—
October 2005 v5.1.0	Updated for the Quartus II software version 5.1.	—
May 2005 v5.0.0	<ul style="list-style-type: none"> <li>• Minor updates for Quartus II software 5.0</li> </ul>	—
December 2004 v2.1	<ul style="list-style-type: none"> <li>• Chapter 9 was formerly Chapter 8.</li> <li>• Updates to tables and figures.</li> <li>• New functionality for Quartus II software 4.2.</li> </ul>	—
June 2004 v2.0	<ul style="list-style-type: none"> <li>• Updates to tables, figures.</li> <li>• New functionality for Quartus II software 4.1.</li> </ul>	—
February 2004 v1.0	Initial release.	—

## Introduction

The phenomenal growth in design size and complexity continues to make design verification a critical bottleneck for current FPGA systems. Limited access to internal signals, complex FPGA packages, and PCB electrical noise all contribute to making design debugging the most challenging process of the design cycle. More than 50% of the design cycle time can be spent on debugging and verifying the design. To help with the process of design debugging, Altera® provides a solution that enables a designer to examine the behavior of internal signals, without using extra I/O pins, while the design is running at full speed on an FPGA device.

The SignalTap® II Embedded Logic Analyzer is scalable, easy to use, and is included with the Quartus® II software subscription. This logic analyzer helps debug an FPGA design by probing the state of the internal signals in the design without the use of external equipment. Defining custom trigger-condition logic provides greater accuracy and improves the ability to isolate problems. The SignalTap II Embedded Logic Analyzer does not require external probes, or changes to the design files to capture the state of the internal nodes or I/O pins in the design. All captured signal data is conveniently stored in device memory until the designer is ready to read and analyze the data.

The topics in this chapter include:

- “On-Chip Debugging Tool Comparison” on page 13-5
- “Design Flow Using the SignalTap II Logic Analyzer” on page 13-7
- “SignalTap II Logic Analyzer Task Flow” on page 13-8
- “Add the SignalTap II Logic Analyzer to Your Design” on page 13-10
- “Configure the SignalTap II Logic Analyzer” on page 13-18
- “Define Triggers” on page 13-30
- “Program the Target Device or Devices” on page 13-57
- “Run the SignalTap II Logic Analyzer” on page 13-59
- “View, Analyze, and Use Captured Data” on page 13-63
- “Other Features” on page 13-67
- “SignalTap II Scripting Support” on page 13-72
- “Design Example: Using SignalTap II Logic Analyzers in SOPC Builder Systems” on page 13-77
- “Custom Triggering Flow Application Examples” on page 13-77

The SignalTap II Embedded Logic Analyzer is a next-generation, system-level debugging tool that captures and displays real-time signal behavior in a system-on-a-programmable-chip (SOPC) or any FPGA design. The SignalTap II Embedded Logic Analyzer supports the highest number of channels, largest sample depth, and fastest clock speeds of any embedded logic analyzer in the programmable logic market. [Figure 13-1](#) shows a block diagram of the components that make up the SignalTap II Embedded Logic Analyzer.

**Figure 13-1. SignalTap II Logic Analyzer Block Diagram** *Note (1)*

**Note to Figure 13-1:**

- (1) This diagram assumes that the SignalTap II Logic Analyzer was compiled with the design as a separate design partition using the Quartus II Incremental Compilation feature. This is the default setting for new projects in the Quartus II software. If incremental compilation is disabled or not used, the SignalTap II logic is integrated with the design. For information about the use of incremental compilation with SignalTap II, refer to [“Faster Compilations with Quartus II Incremental Compilation”](#) on page 13-51.

This chapter is intended for any designer who wants to debug their FPGA design during normal device operation without the need for external lab equipment. Because the SignalTap II Embedded Logic Analyzer is similar to traditional external logic analyzers, familiarity with external logic analyzer operations is helpful but not necessary. To take advantage of faster compile times when making changes to the SignalTap II Logic Analyzer, knowledge of the Quartus II Incremental Compilation feature is helpful.

For information about using the Quartus II Incremental Compilation feature, refer to the *Incremental Compilation for Hierarchical and Team-Based Design* chapter in the *Quartus II Handbook*.

## Hardware and Software Requirements

The following components are required to perform logic analysis with the SignalTap II Embedded Logic Analyzer:

- Quartus II design software  
or  
Quartus II Web Edition (with TalkBack feature enabled)  
or  
SignalTap II Logic Analyzer standalone software
- Download/Upload Cable
- Altera development kit or user design board with JTAG connection to device under test

Captured data is stored in the device's memory blocks and transferred to the Quartus II software waveform display with a JTAG communication cable, such as EthernetBlaster or USB-Blaster™. [Table 13–1](#) summarizes some of the features and benefits of the SignalTap II Embedded Logic Analyzer.

**Table 13–1. SignalTap II Features and Benefits (Part 1 of 2)**

Feature	Benefit
Multiple logic analyzers in a single device	Captures data from multiple clock domains in a design at the same time
Multiple logic analyzers in multiple devices in a single JTAG chain	Simultaneously captures data from multiple devices in a JTAG chain
Plug-In Support	Easily specifies nodes, triggers, and signal mnemonics for IP, such as the Nios® II embedded processor
Up to 10 basic or advanced trigger conditions for each analyzer instance	Enables more complex data capture commands to be sent to the logic analyzer, providing greater accuracy and problem isolation
Power-Up Trigger	Captures signal data for triggers that occur after device programming but before manually starting the logic analyzer
State-Based Triggering Flow	Enables you to organize your triggering conditions to precisely define what your embedded logic analyzer will capture
Incremental Compilation	Modifies the SignalTap II Logic Analyzer monitored signals and triggers without performing a full compilation, saving time
Flexible buffer acquisition modes	Allows more accurate data collection by setting each trigger to sample at different ranges relative to the triggering event, in circular or segmented modes

**Table 13–1. SignalTap II Features and Benefits (Part 2 of 2)**

Feature	Benefit
MATLAB integration with included MEX function	Acquires the SignalTap II Logic Analyzer captured data into a MATLAB integer matrix
Up to 1,024 channels in each device	Samples many signals and wide bus structures
Up to 128K samples in each device	Captures a large sample set for each channel
Fast clock frequencies	Collects sample data at up to 270 MHz
Resource usage estimator	Provides estimate of logic and memory device resources used by SignalTap II Embedded Logic Analyzer configurations
No additional cost	The SignalTap II Logic Analyzer is included with a Quartus II subscription and with the Quartus II Web Edition (with TalkBack enabled)

For a list of supported device families, refer to the Quartus II Help.

## On-Chip Debugging Tool Comparison

The Quartus II software provides a number of different ways to help debug your FPGA design after programming the device. The SignalTap II Logic Analyzer, SignalProbe, and the Logic Analyzer Interface (LAI) share some similar features, but each has its own advantages. In some debugging situations, it can be difficult to decide which tool is best to use or whether multiple tools are required. Table 13–2 compares common debugging features between these tools and provides suggestions about which is the best tool to use for a given feature.

**Table 13–2. Suggested On-Chip Debugging Tools for Common Debugging Features *Note (1)* (Part 1 of 2)**

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Embedded Analyzer	Description
Large Sample Depth	N/A	✓	—	An external logic analyzer used with the LAI has a bigger buffer to store more captured data than the SignalTap II Logic Analyzer. No data is captured or stored with SignalProbe.
Ease in Debugging Timing Issue	N/A	✓	—	An external logic analyzer used with the LAI provides you with access to timing mode, enabling you to debug combined streams of data.
Minimal Effect on Logic Design	✓	✓ (2)	✓ (2)	The LAI adds minimal logic to a design, requiring fewer device resources. The SignalTap II Logic Analyzer has little effect on the design when it is set as a separate design partition using incremental compilation. SignalProbe incrementally routes nodes to pins, not affecting the design at all.
Short Compile and Recompile Time	✓	✓ (2)	✓ (2)	SignalProbe attaches incrementally routed signals to previously reserved pins, requiring very little recompilation time to make changes to source signal selections. The SignalTap II Logic Analyzer and the LAI can take advantage of incremental compilation to refit their own design partitions to decrease recompilation time.
Triggering Capability	N/A	✓	✓	The SignalTap II Logic Analyzer offers triggering capabilities that are comparable to commercial logic analyzers.
I/O Usage	—	—	✓	No additional output pins are required with the SignalTap II Logic Analyzer. Both the LAI and SignalProbe require I/O pin assignments.

**Table 13–2. Suggested On-Chip Debugging Tools for Common Debugging Features *Note (1)* (Part 2 of 2)**

Feature	SignalProbe	Logic Analyzer Interface (LAI)	SignalTap II Embedded Analyzer	Description
<b>Acquisition Speed</b>	N/A	—	✓	The SignalTap II Logic Analyzer can acquire data at speeds of over 200 MHz. The same acquisition speeds are obtainable with an external logic analyzer used with the LAI, but signal integrity issues may limit this.
<b>No JTAG Connection Required</b>	✓	—	—	An FPGA design with the SignalTap II Logic Analyzer or the LAI requires an active JTAG connection to a host running the Quartus II software. SignalProbe does not require a host for debugging purposes.
<b>External Equipment</b>	—	—	✓	The SignalTap II Logic Analyzer logic is completely internal to the programmed FPGA device. No extra equipment is required other than a JTAG connection from a host running the Quartus II software or the stand-alone SignalTap II software. SignalProbe and the LAI require the use of external debugging equipment, such as multimeters, oscilloscopes, or logic analyzers.

**Notes to Table 13–2:**

- (1) ✓ indicates the suggested best tool for the feature. — indicates that while the tool is available for that feature, that tool may not give the best results. N/A indicates that the feature is not applicable for the selected tool.
- (2) When used with incremental compilation.

If you have signals that you want to monitor with external equipment without adding the logic resources required by the SignalTap II Logic Analyzer, consider the use of these other tools available in the Quartus II software. Signals can be quickly routed out to reserved I/O pins as part of an ECO change using SignalProbe, while multiplexed banks of many signals can be made visible on only a few pins with the use of the LAI.

For information about the use of these tools, refer to the *Quick Design Debugging Using SignalProbe* and *In-System Debugging Using External Logic Analyzers* chapters in volume 3 of the *Quartus II Handbook*.

## Design Flow Using the SignalTap II Logic Analyzer

Figure 13–2 shows a typical overall FPGA design flow for using the SignalTap II Logic Analyzer in your design. A SignalTap II file (.stp) is added to and enabled in your project, or a SignalTap II HDL function, created with the MegaWizard® Plug-In Manager, is instantiated in your design. The diagram shows the flow of operations from initially adding the SignalTap II Logic Analyzer to your design to the final device configuration, testing, and debugging.

Figure 13–2. SignalTap II FPGA Design and Debugging Flow

## SignalTap II Logic Analyzer Task Flow

To use the SignalTap II Logic Analyzer to debug your design, you perform a number of tasks to add, configure, and run the logic analyzer. [Figure 13-3](#) shows a typical flow of the tasks you complete to debug your design. Refer to the appropriate section of this chapter for more information about each of these tasks.

**Figure 13-3. SignalTap II Logic Analyzer Task Flow**

## Add the SignalTap II Logic Analyzer to Your Design

Create a SignalTap II file or create a parameterized HDL instance representation of the logic analyzer using the MegaWizard Plug-In Manager. If you want to monitor multiple clock domains simultaneously, you can add additional instances of the logic analyzer to your design, limited only by the available resources in your device.

## Configure the SignalTap II Logic Analyzer

Once the SignalTap II Logic Analyzer is added to your design, you configure it to monitor the signals you want. You can manually add signals or use a plug-in, such as the Nios II plug-in, to quickly add entire sets of associated signals for a particular IP. You can also specify settings for the data capture buffer, such as its size, the method in which data is captured and stored, and the device memory type to use for the buffer in devices that support memory type selection.

## Define Triggers

The SignalTap II Logic Analyzer continuously captures data while it is running. To capture and store specific signal data, you set up triggers that tell the logic analyzer under what conditions to stop capturing data. The SignalTap II Logic Analyzer lets you define Runtime Triggers that range from very simple, such as the rising edge of a single signal, to very complex, involving groups of signals, extra logic, and multiple conditions. Power-Up Triggers give you the ability to capture data from trigger events occurring immediately after the device enters user-mode after configuration.

## Compile the Design

With the SignalTap II file configured and triggers defined, you compile your project as usual to include the logic analyzer in your design. Since you may need to frequently change monitored signal nodes or adjust trigger settings during debugging, it is recommended that you use the incremental compilation feature built into the SignalTap II Logic Analyzer, along with Quartus II incremental compilation, to reduce recompile times.

## Program the Target Device or Devices

When you are debugging a design with the SignalTap II Logic Analyzer, you can program a target device directly from the SignalTap II file without using the Quartus II Programmer. You can also program multiple devices with different designs and simultaneously debug them.

## Run the SignalTap II Logic Analyzer

In normal device operation, you control the logic analyzer through the JTAG connection, specifying when to start looking for your trigger conditions to begin capturing data. With Runtime or Power-Up Triggers, you read and transfer the captured data from the on-chip buffer to the SignalTap II file for analysis.

## View, Analyze, and Use Captured Data

Once you have captured data and read it into the SignalTap II file, it is available for analysis and use in the debugging process. Either manually or with a plug-in, you can set up mnemonic tables to make it easier to read and interpret the captured signal data. To speed up debugging, use the Locate feature in the SignalTap II node list to find the locations of problem nodes in other tools in the Quartus II software. Save the captured data for later analysis, or convert it to other formats for sharing and further study.

## Add the SignalTap II Logic Analyzer to Your Design

Because the SignalTap II Logic Analyzer is implemented in logic on your target device, it must be added to your FPGA design as another part of the design itself. There are two ways to generate the SignalTap II Logic Analyzer and add it to your design for debugging:

- Create a SignalTap II file (.stp) and use the SignalTap II Editor to configure the details of the logic analyzer
- Create and configure the SignalTap II file with the MegaWizard Plug-In Manager and instantiate it in your design

## Creating and Enabling a SignalTap II File

To create an embedded logic analyzer, you can use an existing SignalTap II file or create a new file. Once a file is created or selected, it must be enabled in the project where it is used.

### *Creating a SignalTap II File*

The SignalTap II file contains the SignalTap II Logic Analyzer settings and the captured data for viewing and analysis. To create a new SignalTap II file, perform the following steps:

1. On the File menu, click **New**.
2. In the New dialog box, click the **Other Files** tab, and select **SignalTap II Logic Analyzer File**.

3. Click **OK**.

To open an existing SignalTap II file already associated with your project, on the Tools menu, click **SignalTap II Logic Analyzer**. You can also use this method to create a new SignalTap II file if no SignalTap II file exists for the current project.

To open an existing file, on the File menu, click **Open** and select a SignalTap II file (Figure 13-4).

**Figure 13-4. SignalTap II Editor**

### *Enabling and Disabling a SignalTap II File for the Current Project*

Whenever you save a new SignalTap II file, the Quartus II software asks you if you want to enable the file for the current project. However, you can add this file manually, change the selected SignalTap II file, or completely disable the logic analyzer by performing the following steps:

1. On the Assignments menu, click **Settings**. The **Settings** dialog box appears.
2. In the **Category** list, select **SignalTap II Logic Analyzer**. The **SignalTap II Logic Analyzer** page appears.

3. Turn on **Enable SignalTap II Logic Analyzer**. Turn off this option to disable the logic analyzer, completely removing it from your design.
4. In the **SignalTap II File name** box, type the name of the SignalTap II file you want to include with your design, or browse to and select a file name.
5. Click **OK**.

## Using the MegaWizard Plug-In Manager to Create Your Embedded Logic Analyzer

Alternatively, you can create a SignalTap II Logic Analyzer instance by using the MegaWizard Plug-In Manager. The MegaWizard Plug-In Manager generates an HDL file that you instantiate in your design. You can also use a hybrid approach in which you instantiate the MegaWizard Plug-In Manager file in your HDL, and then use the method described in [“Creating and Enabling a SignalTap II File”](#) on page 13–10.

### *Creating an HDL Representation Using the MegaWizard Plug-In Manager*

The Quartus II software allows you to easily create your SignalTap II Logic Analyzer using the MegaWizard Plug-In Manager. To implement the SignalTap II megafunction, perform the following steps:

1. On the Tools menu, click **MegaWizard Plug-In Manager**. Page 1 of the **MegaWizard Plug-In Manager** dialog box appears.
2. Select **Create a new custom megafunction variation**.
3. Click **Next**.
4. In the **Installed Plug-Ins** list, expand the **JTAG-accessible Extensions** folder, and select **SignalTap II Logic Analyzer**. Select an output file type and enter the desired name of the SignalTap II megafunction. You can choose AHDL (.tdf), VHDL (.vhd), or Verilog HDL (.v) as the output file type ([Figure 13–5](#)).

**Figure 13–5. Creating the SignalTap II Logic Analyzer in the MegaWizard Plug-In Manager**

5. Click **Next**.
6. Configure the analyzer by specifying the **Sample depth**, **RAM Type**, **Data input port width**, **Trigger levels**, **Trigger input port width**, and whether to enable an external **Trigger in** or **Trigger out** (Figure 13–6).

For information about these settings, refer to “Configure the SignalTap II Logic Analyzer” on page 13–18 and “Define Triggers” on page 13–30.

Figure 13–6. Select Logic Analyzer Parameters

7. Click **Next**.
8. Set the **Trigger level** options by selecting **Basic** or **Advanced** (Figure 13–7). If you select **Advanced** for any trigger level, the next page of the MegaWizard Plug-In Manager displays the Advanced Trigger Condition Editor. You can configure an advanced trigger expression using the number of signals you specified for the trigger input port width.

You cannot define a Power-Up Trigger using the MegaWizard Plug-In Manager. Refer to “Define Triggers” on page 13–30 to learn how to do this using the SignalTap II file.

Figure 13–7. MegaWizard Basic and Advanced Trigger Options

9. On the final page of the MegaWizard Plug-In Manager, select any additional files you want to create and click **Finish** to create an HDL representation of the SignalTap II Logic Analyzer.

For information about the configuration settings options in the MegaWizard Plug-In Manager, refer to [“Configure the SignalTap II Logic Analyzer” on page 13–18](#). For information about defining triggers, refer to [“Define Triggers” on page 13–30](#).

*SignalTap II Megafunction Ports*

Table 13–3 provides information about the SignalTap II megafunction ports.

For the most current information about the ports and parameters for this megafunction, refer to the latest version of the Quartus II Help.

<b>Table 13–3. SignalTap II Megafunction Ports</b>			
<b>Port Name</b>	<b>Type</b>	<b>Required</b>	<b>Description</b>
acq_data_in	Input	No	This set of signals represents the set of signals that are monitored in the SignalTap II Logic Analyzer.
acq_trigger_in	Input	No	This set of signals represents the set of signals that are used to trigger the analyzer.
acq_clk	Input	Yes	This port represents the sampling clock that the SignalTap II Logic Analyzer uses to capture data.
trigger_in	Input	No	This signal is used to trigger the SignalTap II Logic Analyzer.
trigger_out	Output	No	This signal is enabled when the trigger event occurs.

*Instantiating the SignalTap II Logic Analyzer in Your HDL*

Instantiating the logic analyzer in your HDL is similar to instantiating any other Verilog HDL or VHDL megafunction in your design. Add the code from the files that are generated by the MegaWizard Plug-In Manager to your design, mapping the signals in your design to the appropriate SignalTap II megafunction ports. You can instantiate up to 127 analyzers in your design, or as many as physically fit in the FPGA. Once you have instantiated the SignalTap II file in your HDL file, compile your Quartus II project to fit the logic analyzer in the target FPGA.

To capture and view the data, you must create a SignalTap II file from your SignalTap II HDL output file. To do this, on the File menu, point to Create/Update, and click **Create SignalTap II File from Design Instance(s)**.

If you make any changes to your design or the SignalTap II instance, recreate or update the SignalTap II file with this command. This ensures that the SignalTap II file is always compatible with the SignalTap II instance in your design. If the SignalTap II file is not compatible with the SignalTap II instance in your design, you may not be able to control the SignalTap II Logic Analyzer after it is programmed into your device.

For information about SignalTap II file compatibility with programmed SignalTap II instances, refer to [“Program the Target Device or Devices” on page 13–57](#).

## Embedding Multiple Analyzers in One FPGA

The SignalTap II Logic Analyzer includes support for multiple logic analyzers in an FPGA device. This feature allows you to create a unique logic analyzer for each clock domain in the design. As multiple instances of the analyzer are added to the SignalTap II file, the resource usage increases proportionally.

In addition to debugging multiple clock domains, this feature allows you to apply the same SignalTap II settings to a group of signals in the same clock domain. For example, if you have a set of signals that must use a sample depth of 64K and another set of signals in the same clock domain requires a sample depth of 1K, you can create two instances to meet these needs.

To create multiple analyzers, on the Edit menu, click **Create Instance**, or right-click in the Instance Manager window and click **Create Instance**.

Each instance of the SignalTap II Logic Analyzer can be configured independently. The icon in the Instance Manager for the currently active instance that is available for configuration is highlighted in color and surrounded by a blue box. To configure a different instance, double-click the icon or name of another instance in the Instance Manager.

## Monitoring FPGA Resources Used by the SignalTap II Logic Analyzer

The SignalTap II Logic Analyzer has a built-in resource estimator that calculates the logic resources and amount of memory that each SignalTap II Logic Analyzer uses. You can see the resource usage of each logic analyzer instance and the total resources used in the columns of the Instance Manager section of the SignalTap II Editor. This feature is useful when device resources are limited and you must know what device resources the SignalTap II Logic Analyzer uses. The value reported in the resource usage estimator may vary by as much as 5% from the actual resource usage.

Table 13–4 shows the SignalTap II Logic Analyzer M4K memory block resource usage for the listed devices per signal width and sample depth.

**Table 13–4. SignalTap II Logic Analyzer M4K Block Utilization for Stratix II, Stratix, Stratix GX, and Cyclone Devices** *Note (1)*

Signals (Width)	Samples (Depth)			
	256	512	2,048	8,192
8	< 1	1	4	16
16	1	2	8	32
32	2	4	16	64
64	4	8	32	128
256	16	32	128	512

*Note to Table 13–4:*

- (1) When you configure a SignalTap II Logic Analyzer, the Instance Manager reports an estimate of the memory bits and logic elements required to implement the given configuration.

## Configure the SignalTap II Logic Analyzer

The SignalTap II file provides many options for configuring instances of the logic analyzer. Some of the settings are similar to those found on traditional external logic analyzers. Other settings are unique to the SignalTap II Logic Analyzer because of the requirements for configuring an embedded logic analyzer. All settings give you the ability to configure the logic analyzer the way you want to help debug your design.

Some settings can only be adjusted when you are viewing Run-Time Trigger conditions instead of Power-Up Trigger conditions. To learn about Power-Up Triggers and viewing different trigger conditions, refer to “[Creating a Power-Up Trigger](#)” on page 13–45.

### Assigning an Acquisition Clock

You must assign a clock signal to control the acquisition of data by the SignalTap II Logic Analyzer. The logic analyzer samples data on every rising edge of the acquisition clock. You can use any signal in your design as the acquisition clock. However, for best results, Altera recommends that you use a global, non-gated clock for data acquisition. Using a gated clock as your acquisition clock can result in unexpected data that does not accurately reflect the behavior of your design. The Quartus II Classic Timing Analyzer shows the maximum acquisition clock frequency at which you can run your design.

To assign an acquisition clock, perform the following steps:

1. In the SignalTap II Logic Analyzer window, click the **Setup** tab.
2. Click **Browse** next to the **Clock** field in the Signal Configuration pane. The **Node Finder** dialog box appears.
3. From the **Filter** list, select **SignalTap II: post-fitting**  
*or*  
**SignalTap II: pre-synthesis**.
4. In the **Named** field, type the exact name of a node that you want to use as your sample clock, or search for a node using a partial name and wildcard characters.
5. To start the node search, click **List**.
6. In the **Nodes Found** list, select the node that represents the design's global clock signal.
7. Add the selected node name to the **Selected Nodes** list by clicking ">" or by double-clicking the node name.
8. Click **OK**. The node is now specified as the acquisition clock in the SignalTap II Editor.

If you do not assign an acquisition clock in the SignalTap II Editor, the Quartus II software automatically creates a clock pin called `auto_stp_external_clk`.

You must make a pin assignment to this pin independently from the design. You must ensure that a clock signal in your design drives the acquisition clock.

For information about assigning signals to pins, refer to the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

## Adding Signals to the SignalTap II File

While configuring the logic analyzer, you add signals to the node list in the SignalTap II file to select which signals in your design you want to monitor. Selected signals are also used to define triggers. You can assign the following two types of signals to your SignalTap II file:

- **Pre-synthesis**—This signal exists after design elaboration, but before any synthesis optimizations are done. This set of signals should reflect your Register Transfer Level (RTL) signals.

- **Post-fitting**—This signal exists after physical synthesis optimizations and place-and-route.

If you are not using incremental compilation, add only pre-synthesis signals to your SignalTap II file. Using pre-synthesis is particularly useful if you want to add a new node after you have made design changes. To do this, on the Processing menu, point to Start and click **Start Analysis & Elaboration**.

Signals shown in blue text are post-fit node names. Signals shown in black text are pre-synthesis node names.

After successful Analysis and Elaboration, the signals shown in red text are invalid signals. Unless you are certain that these signals are valid, you must remove them from the SignalTap II file for correct operation. The SignalTap II Health Monitor also indicates if an invalid node name exists in the SignalTap II file.

As a general guideline, signals can be tapped if a routing resource (row or column interconnects) exists to route the connection to the SignalTap II instance. For example, signals that exist in the I/O element (IOE) cannot be directly tapped because there are no direct routing resources from the signal in an IOE to a core logic element. For input pins, you can tap the signal that is driving a Logic Array Block (LAB) from an IOE, or, for output pins, you can tap the signal from the LAB that is driving an IOE.

When adding pre-synthesis signals, all connections made to the SignalTap II Logic Analyzer are made prior to synthesis. Logic and routing resources are allocated during recompilation to make the connection as if a change in your design files had been made. As such, pre-synthesis signal names for signals driving to and from IOEs will coincide with the signal names assigned to the pin.

In the case of post-fit signals, connections that you make to the SignalTap II Logic Analyzer are the signal names from the actual atoms in your post-fit netlist. A connection can only be made if the signals are part of the existing post-fit netlist and existing routing resources are available from the signal of interest to the SignalTap II Logic Analyzer. In the case of post-fit output signals, tap the COMBOUT or REGOUT signal that drives the IOE block. For post-fit input signals, signals driving into the core logic will coincide with the signal name assigned to the pin.

If you are tapping the signal from the atom that is driving an IOE, be aware that the signal may be inverted due to NOT-gate push back. You can check this by locating the signal in either the Resource Property Editor or the Technology Map Viewer. The Technology Map viewer and the Resource Property Editor are also helpful in finding post-fit node names.

For information about cross-probing to source design file and other Quartus II windows, refer to the *Analyzing Designs with Quartus II Netlist Viewers* chapter in volume 1 of the *Quartus II Handbook*.

For more information about the use of incremental compilation with the SignalTap II Logic Analyzer, refer to “[Faster Compilations with Quartus II Incremental Compilation](#)” on page 13–51.

### Signal Preservation

Many of your RTL signals are optimized during the process of synthesis and place-and-route. The RTL signal names frequently may not appear in the post-fit netlist after optimizations. This can cause a problem when you use the incremental compilation flow with the SignalTap II Logic Analyzer. Since only post-fitting signals can be added to the SignalTap II Logic Analyzer in partitions of type **post-fit**, RTL signals that you want to monitor may not be available, preventing their usage. To avoid this issue, you can use synthesis attributes to preserve signals during synthesis and place-and-route. When the Quartus II software encounters these synthesis attributes, it does not perform any optimization on the specified signals, forcing them to continue to exist in the post-fit netlist. However, if you do this, you could see an increase in resource utilization or a decrease in timing performance. The two attributes you can use are:

- **keep**—Ensures that combinational signals are not removed
- **preserve**—Ensures that registers are not removed

For more information about using these attributes, refer to the *Quartus II Integrated Synthesis* chapter in volume 1 of the *Quartus II Handbook*.

If you are debugging an IP core, such as the Nios II CPU, or other encrypted IP, you may need to preserve nodes from the core to make them available for debugging with the SignalTap II Logic Analyzer. This is often necessary when a plug-in is used to add a group of signals for a particular IP. To do this, on the Assignments menu, click **Settings**. In the **Category** list, select **Analysis & Synthesis Settings**. Turn on **Create debugging nodes for IP cores** to make these nodes available to the SignalTap II Logic Analyzer.

### Assigning Data Signals

To assign data signals, perform the following steps:

1. Perform Analysis and Elaboration, Analysis and Synthesis, or compile your design.
2. In the SignalTap II Logic Analyzer window, click the **Setup** tab.
3. Double-click anywhere in the node list of the SignalTap II Editor to open the **Node Finder** dialog box.
4. In the **Fitter** list, select **SignalTap II: pre-synthesis** or **SignalTap II: post-fitting**. Only signals listed under one of these filters can be added to the SignalTap II node list. Signals cannot be selected from any other filters.

If you use Incremental Compilation flow with SignalTap II, pre-synthesis nodes will not be connected to the SignalTap II Logic Analyzer if the affected partition is of the post-fit type. Any pre-synthesis nodes added to a partition of type post-fit may not be connected to the SignalTap II Logic Analyzer. A critical warning is issued for all pre-synthesis node names that are not found in the post-fit netlist. Altera recommends that you do not add a mix of pre-synthesis and post-fitting signals within the same partition. For more details, refer to [“Using Incremental Compilation with the SignalTap II Logic Analyzer”](#) on page 13–52.

5. In the **Named** field, type a node name, or search for a particular node by entering a partial node name along with wildcard characters. To start the node name search, click **List**.
6. In the **Nodes Found** list, select the node or bus you want to add to the SignalTap II file.
7. Add the selected node name(s) to the **Selected Nodes** list by clicking “>” or by double-clicking the node name(s).
8. To insert the selected nodes in the SignalTap II file, click **OK**. With the default colors set for the SignalTap II Logic Analyzer, a pre-synthesis signal in the list is shown in black, and a post-fitting signal is shown in blue.

You can also drag and drop signals from the **Node Finder** dialog box into a SignalTap II file.

### *Node List Signal Use Options*

Once a signal is added to the node list, you can select options that specify how the signal is used with the logic analyzer. You can turn off the ability of a signal to trigger the analyzer by disabling the **Trigger Enable** for that signal in the node list in the SignalTap II file. This option is useful when you want to see only the captured data for a signal, and you are not using that signal as part of a trigger.

You can turn off the ability to view data for a signal by disabling the **Data Enable** column. This option is useful when you want to trigger on a signal, but have no interest in viewing data for that signal.

For information about using signals in the node list to create SignalTap II trigger conditions, refer to [“Define Triggers” on page 13–30](#).

### *Untappable Signals*

Not all of the post-fitting signals in your design are available in the **SignalTap II: post-fitting** filter in the **Node Finder** dialog box. The following signal types cannot be tapped:

- Post-fit output pins—You cannot tap a post-fit output pin directly. To make an output signal visible, tap the register or buffer that drives the output pin.
- Signals that are part of a carry chain—You cannot tap the carry out (`cout0` or `cout1`) signal of a logic element. Due to architectural restrictions, the carry out signal can only feed the carry in of another logic element (LE).
- JTAG Signals—You cannot tap the JTAG control (`TCK`, `TDI`, `TDO`, and `TMS`) signals.
- `altgxb` megafunction—You cannot directly tap any ports of an `altgxb` instantiation.
- LVDS—You cannot tap the data output from a serializer/deserializer (SERDES) block.

### **Adding Signals with a Plug-In**

Instead of adding individual or grouped signals through the **Node Finder**, you can add groups of relevant signals of a particular type of IP through the use of a plug-in. The SignalTap II Logic Analyzer comes with one plug-in already installed for the Nios II processor. Besides easy signal addition, plug-ins also provide a number of other features, such as pre-designed mnemonic tables, useful for trigger creation and data viewing, as well as the ability to disassemble code in captured data.

The Nios II plug-in, for example, creates one mnemonic table in the **Setup** tab, and two tables in the **Data** tab:

- **Nios II Instruction (Setup tab)**—Capture all the required signals for triggering on a selected instruction address.
- **Nios II Instance Address (Data tab)**—Display address of executed instructions in hexadecimal format or as a programming symbol name if defined in an optional Executable and Linking Format (.elf) file.
- **Nios II Disassembly (Data tab)**—Displays disassembled code from the corresponding address.

For information about the other features plug-ins provided, refer to “Define Triggers” on page 13–30 and “View, Analyze, and Use Captured Data” on page 13–63.

To add signals to the SignalTap II file using a plug-in, perform the following steps after running Analysis and Elaboration on your design:

1. Right-click in the node list. On the **Add Nodes with Plug-In** submenu, click the name of the plug-in you want to use, such as the included plug-in named **Nios II**.

If the intellectual property (IP) for the selected plug-in does not exist in your design, a message appears informing you that you cannot use the selected plug-in.

2. The **Select Hierarchy Level** dialog box appears showing the IP hierarchy of your design (Figure 13–8). Select the **IP** that contains the signals you want to monitor with the plug-in, and click **OK**.

**Figure 13–8. IP Hierarchy Selection**

3. If all the signals in the plug-in are available, a dialog box may appear, depending on the plug-in selected, where you can set any available options for the plug-in. With the Nios II plug-in, you can optionally select an Executable and Linking Format (.elf) file containing program symbols from your Nios II Integrated Development Environment (IDE) software design. Set options for the selected plug-in as desired, and click **OK**.

To make sure all the required signals are available, turn on the **Create debugging nodes for IP cores** option in the Quartus II Analysis & Synthesis settings.

All the signals included in the plug-in are added to the node list.

## Specifying the Sample Depth

The sample depth specifies the number of samples that are captured and stored for each signal in the captured data buffer. To set the sample depth, select the desired number of samples to store in the **Sample Depth** list. The sample depth ranges from 0 to 128K.

If device memory resources are limited, you may not be able to successfully compile your design with the sample buffer size you have selected. Try reducing the sample depth to reduce resource usage.

## Capturing Data to a Specific RAM Type

When you use the SignalTap II Logic Analyzer with some devices, you have the option to select the RAM type where acquisition data is stored. RAM selection allows you to preserve a specific memory block for your design and allocate another portion of memory for SignalTap II data acquisition. For example, if your design implements a large buffering application such as a system cache, it is ideal to place this application into M-RAM blocks so that the remaining M512 or M4K blocks are used for SignalTap II data acquisition.

To select the RAM type to use for the SignalTap II buffer, select it from the **RAM type** list. Use this feature when the acquired data (as reported by the SignalTap II resource estimator) is not larger than the available memory of the memory type that you have selected in the FPGA.

## Choosing the Buffer Acquisition Mode

The buffer acquisition type selection feature in the SignalTap II Logic Analyzer lets you choose how the captured data buffer is organized and can potentially reduce the amount of memory that is required for SignalTap II data acquisition. You can choose to use either a circular buffer, which allocates the entire sample depth to a single buffer, or a segmented buffer, which splits the buffer space into a number of separate even sized segments. Figure 13–9 illustrates the differences between the two buffer types.

**Figure 13–9. Buffer Type Comparison in the SignalTap II Logic Analyzer** *Note (1)*

**Note to Figure 13–9:**

- (1) Both circular and segmented buffers can use a predefined trigger position or define a custom trigger position using the **State-Based Triggering** tab. Refer to [“Specifying the Trigger Position”](#) on page 13–44 for more details.

### Circular Buffer

The circular buffer (Figure 13–9 (a)) is the default buffer type used by the SignalTap II Logic Analyzer. While the logic analyzer is running, data is stored in the buffer until it fills up, at which point new data replaces the oldest data. This continues until a specified trigger event occurs. When this happens, the logic analyzer continues to capture data after the trigger event until the buffer is full, based on the circular buffer trigger position setting in the Signal Configuration pane in the SignalTap II file. Select a setting from the list to choose whether to capture the majority of the data before (**Post trigger position**) or after (**Pre trigger position**) the trigger occurs or to center the trigger position in the data (**Center trigger position**). Another option is to use the custom state-based triggering flow to define your desired triggering position precisely. You can also choose to continuously capture data until the logic analyzer is stopped.

For more information, refer to “Specifying the Trigger Position” on page 13–44.

### Segmented Buffer

The segmented buffer (Figure 13–9 (b)) organizes the buffer into a number of separate, evenly sized segments. This type of buffer organization makes it easier to debug systems that contain relatively infrequent recurring events. Figure 13–10 shows an example of this type of buffer system.

**Figure 13–10. Example System that Generates Recurring Events**

The SignalTap II Logic Analyzer verifies the functionality of the design shown in Figure 13–10 to ensure that the correct data is written to the SRAM controller. The buffer acquisition in the SignalTap II Logic

Analyzer allows you to monitor the RDATA port when H'0F0F0F0F is sent into the RADDR port. You can monitor multiple read transactions from the SRAM device without running the SignalTap II Logic Analyzer again. The buffer acquisition feature allows you to segment the memory so that you can capture the same event multiple times without wasting the allocated memory. The number of cycles that are captured depends on the number of segments that you have specified under the **Data** settings.

To enable and configure buffer acquisition, select **Segmented** in the SignalTap II Editor, and select the number of segments to use. In the example, selecting sixty-four, 64-sample segments allows you to capture 64 read cycles when the RADDR signal is H'0F0F0F0F.

For more information about the buffer acquisition mode, refer to *Setting the Buffer Acquisition Mode* in the Quartus II Help.

## Managing Multiple SignalTap II Files and Configurations

In some cases you may have more than one SignalTap II file in one design. Each file potentially has a different group of monitored signals. These signal groups make it possible to debug different blocks in your design. In turn, each group of signals may also be used to define different sets of trigger conditions. Along with each SignalTap II file, there is also an associated programming file (SRAM Object File (SOF)). The settings in a selected SignalTap II file must match the SignalTap II logic design in the associated SOF file for the logic analyzer to run properly when the device is programmed. Managing all of the SignalTap II files and their associated settings and programming files is a challenging task. To help you manage everything, you can use the **Data Log** feature and the **SOF Manager**.

The **Data Log** allows you to store multiple SignalTap II configurations within a single SignalTap II file. [Figure 13-11](#) shows two signal set configurations with multiple trigger conditions in one SignalTap II file. To toggle between the active configurations, double-click on an entry in the **Data Log**. As you toggle between the different configurations, the signal list and trigger conditions change in the **Setup** tab of the SignalTap II file. The active configuration displayed in the SignalTap II file is indicated by the blue square around the signal set in the **Data log**. To store a configuration in the data log, on the Edit menu, click **Save to Data Log**, or click the **Save to Data Log** button at the top of the Data Log.

**Figure 13–11. Data Log**

The SOF Manager allows you to embed multiple SOFs into one SignalTap II file. Embedding an SOF in a SignalTap II file lets you move the SignalTap II file to a different location, either on the same computer or across a network, without the need to include the associated SOF as a separate file. To embed a new SOF in the SignalTap II file, right-click in the SOF Manager, and click **Attach SOF File** (Figure 13–12).

**Figure 13–12. SOF Manager**

As you switch between configurations in the Data Log, you can extract the SOF that is compatible with that particular configuration and use the programmer in the SignalTap II Logic Analyzer to download the new SOF to the FPGA. In this way, you ensure that the configuration of your SignalTap II file always matches the design programmed into the target device.

## Define Triggers

To capture the data you want at the right time, you need to specify conditions under which the signals you are monitoring display that data. In the SignalTap II Logic Analyzer, these conditions are referred to as triggers, just as they are in conventional external logic analyzers and oscilloscopes. You have many options for creating different types of triggers to help in your debugging.

### Creating Basic Trigger Conditions

The simplest kind of trigger condition you can use is a basic trigger. You select this from the list at the top of the **Trigger Conditions** column in the node list in the SignalTap II Editor. With the trigger type set to **Basic**, you must set the trigger pattern for each signal you have added in the SignalTap II file. To set the trigger pattern, right-click in the **Trigger Conditions** column and click the desired pattern. You can set the trigger pattern to any of the following conditions:

- Don't Care
- Low
- High
- Falling Edge
- Rising Edge
- Either Edge

For buses, you can type a pattern in binary, or right-click and select **Insert Value** to enter the pattern in other number formats. For signals added to the SignalTap II file that have an associated mnemonic table, you can right-click and select an entry from the table to set pre-defined conditions for the trigger.

For more information about the creation and use of mnemonic tables, refer to [“View, Analyze, and Use Captured Data”](#) on page 13–63 and in the Quartus II Help.

For signals added with certain plug-ins, you can easily create basic triggers using pre-defined mnemonic table entries. For example, with the Nios II plug-in, if you have specified an executable software (.elf) file from your Nios II IDE design, you can type the name of a function from your Nios II code. The logic analyzer triggers when the Nios II instruction address matches the address of the specified code function name.

Data capture stops and the data is stored in the buffer when the logical AND of all the signals for a given trigger condition evaluates to TRUE.

## Creating Advanced Trigger Conditions

Along with the SignalTap II Logic Analyzer's basic triggering capabilities, you can build more complex triggers utilizing extra logic that enable you to capture data when a particular combination of conditions exist. If you set the trigger type to **Advanced** at the top of the **Trigger Conditions** column in the node list of the SignalTap II Editor, a new tab named **Advanced Trigger** appears where you can build a complex trigger expression using a simple GUI. You can drag and drop operators into the Advanced Trigger Configuration Editor window to build the complex trigger condition in an expression tree. Double-click operators that you have placed or right-click them and select Properties to configure the operator's settings. [Table 13-5](#) lists the operators you can use.

**Table 13-5. Advanced Triggering Operators** *Note (1)*

Name of Operator	Type
Less Than	Comparison
Less Than or Equal To	Comparison
Equality	Comparison
Inequality	Comparison
Greater Than	Comparison
Greater Than or Equal To	Comparison
Logical NOT	Logical
Logical AND	Logical
Logical OR	Logical
Logical XOR	Logical
Reduction AND	Reduction
Reduction OR	Reduction
Reduction XOR	Reduction
Left Shift	Shift
Right Shift	Shift
Bitwise Complement	Bitwise
Bitwise AND	Bitwise
Bitwise OR	Bitwise
Bitwise XOR	Bitwise
Edge and Level Detector	Signal Detection

*Note to Table 13-5:*

(1) For more information about each of these operators, refer to the Quartus II Help.

You can configure some of the settings for certain operators at run-time. This enables you to change one operator type to another operator type or adjust other settings for an operator without recompiling your design. Operator settings that have a white background on the operator symbol can be changed without recompiling the design.

Adding many objects to the Advanced Trigger Condition Editor can make the workspace cluttered and difficult to read. To keep objects organized while you build your advanced trigger condition, use the right-click menu and select **Arrange All Objects**. You can also use the **Zoom-Out** command to fit more objects into the Advanced Trigger Condition editor window.

### Examples of Advanced Triggering Expressions

The following examples show how to use Advanced Triggering:

- Trigger when bus outa is greater than or equal to outb (Figure 13–13).

**Figure 13–13. Bus outa is Greater Than or Equal to Bus outb**

- Trigger when bus outa is greater than or equal to bus outb, and when the enable signal has a rising edge (Figure 13–14).

**Figure 13–14. Enable Signal has a Rising Edge**

```
Result: outa>=outb&&ELD((enable))
```

- Trigger when bus `outa` is greater than or equal to bus `outb`, or when the `enable` signal has a rising edge. Or, when a bitwise AND operation has been performed between bus `outc` and bus `outd`, and all bits of the result of that operation are equal to 1 (Figure 13–15).

**Figure 13–15. Bitwise AND Operation**

```
Result: outa>=outb||ELD((enable))||(&outc&outd)
```

## Trigger Condition Flow Control

SignalTap II offers multiple triggering conditions to give you more precise control of the method in which data is captured into the acquisition buffers. Trigger Condition Flow control allows you to define the relationship between a set of triggering conditions. SignalTap II gives you two flow control mechanisms for organizing trigger conditions:

- **Sequential Triggering**—The default triggering flow. This flow allows you to define up to ten triggering levels that must be satisfied before the acquisition buffer finishes capturing.
- **Custom State-Based Triggering**—This flow allows you the greatest control over your acquisition buffer. This method allows you to organize trigger conditions into states based on a conditional flow that you define.

Both methods can be used with either a circular buffer or a segmented buffer.

### *Sequential Triggering*

The sequential triggering flow allows you to cascade up to ten levels of triggering conditions. The SignalTap II Logic Analyzer sequentially evaluates each of the triggering conditions. When the last triggering condition evaluates to TRUE, the SignalTap II Logic Analyzer triggers the acquisition buffer. For segmented buffers, every acquisition segment after the first segment triggers on the last triggering condition that you have specified. You can use the simple sequential triggering feature with basic triggers, advanced triggers, or a mix of both. [Figure 13–16](#) illustrates the simple sequential triggering flow for circular and segmented buffers.

Note that the external trigger in is considered as trigger level 0. The external trigger must be evaluated before the main trigger levels are evaluated.

**Figure 13–16. Sequential Triggering Flow Notes (1), (2)**

**Note to Figure 13–16:**

- (1) The Acquisition buffer stops capture when all  $n$  triggering levels are satisfied, where  $n \leq 10$ .
- (2) An external trigger input, if defined, will be evaluated before all other defined trigger conditions are evaluated. For more information about external triggers refer to [“Using External Triggers”](#) on page 13–47.

To configure the SignalTap II Logic Analyzer for Sequential triggering, on the Trigger flow control list in the SignalTap II editor, select **Sequential**. You can select the desired number of trigger conditions by using the **Trigger Conditions** pull-down list. After you select the desired number of trigger conditions, you can configure each trigger condition in the node list. To disable any trigger condition, click the check box next to the trigger condition at the top of the column in the node list. [Figure 13–17](#) shows the setup tab for Sequential Triggering.

Figure 13–17. Setup Tab

### Custom State-Based Triggering

The custom state-based triggering method gives you the most control of triggering condition arrangement. This flow gives you the ability to describe the relationship between triggering conditions precisely, using an intuitive GUI and the SignalTap II Trigger Flow Description Language, a simple description language based upon conditional expressions. Tooltips within the custom triggering flow GUI allow you to describe your desired flow quickly. The custom state-based triggering flow allows for more efficient use of the space available in the acquisition buffer because only specific samples of interest are captured.

Figure 13–18 illustrates the custom state-based triggering flow. Events that trigger the acquisition buffer are organized by a user-defined state diagram. All actions performed by the acquisition buffer are captured by the states and all the transition conditions between the states are defined by the conditional expressions that you specify within each state.

**Figure 13–18. Custom State-Based Triggering Flow** *Note (1), (2)*

**Note to Figure 13–18:**

- (1) You are allowed up to twenty different states.
- (2) An external trigger input, if defined, will be evaluated before any conditions in the custom state-based triggering flow are evaluated. For more information, refer to “Using External Triggers” on page 13–47.

Each state allows you to define a set of conditional expressions. Each conditional expression is a Boolean expression dependent upon a combination of triggering conditions (configured within the **Setup** tab), counters, and status flags. Counters and status flags are resources provided by the Signal Tap II custom-based triggering flow.

Within each conditional expression you define a set of “actions”. Actions include triggering the acquisition buffer to stop capture, a modification to either a counter or status flag, or a state transition.

Trigger actions can apply to either a single segment of a segmented acquisition buffer or to the entire circular acquisition buffer. Each trigger action provides you with an optional count that specifies the number of samples to be captured before stopping acquisition of the current segment. The count argument allows you to control the amount of data captured precisely before and after triggering event.

Resource manipulation actions allow you to increment and decrement counters or set and clear status flags. The counter and status flag resources are used as optional inputs in the conditional expressions. Counters and status flags are useful for counting the number of occurrences of particular events and for aiding in the triggering flow control.

This Signal Tap II custom state-based triggering flow allows you to capture a sequence of events that may not necessarily be contiguous in time; for example, capturing a communication transaction between two devices that includes a handshaking protocol containing a sequence of acknowledgements.

The **State-Based Trigger Flow** tab is the control interface for the custom state-based triggering flow. To enable this tab, on the Trigger Flow Control pull-down list, select **State-based**. (Note that when the **Trigger Flow control** option is set to **Sequential**, the **State-Based Trigger Flow** tab is hidden.)

Figure 13–19 shows the Custom Trigger Flow tab.

**Figure 13–19. State-Based Trigger Flow Tab**

*State-Based Trigger Flow Tab*

The State-Based Trigger Flow tab is partitioned into the following three panes.

- State Diagram Pane
- Resources Pane
- State Machine Pane

### State Diagram Pane

The State Diagram pane provides a graphical overview of the triggering flow that you define. It shows the number of states available and the state transitions between all of the states. You can adjust the number of available states by using the pull-down menu above the graphical overview.

### State Machine Pane

The State Machine pane contains the text entry boxes where you can define the triggering flow and the actions associated with each state. You can define the triggering flow using the Signal Tap II Trigger Flow Description Language, a simple language based upon if-else conditional statements. Tooltips appear when you move the mouse over the cursor, to guide command entry into the state boxes. The GUI provides a syntax check on your flow description in real-time and highlights any errors in the text flow.

Refer to “SignalTap II Trigger Flow Description Language” on page 13–40 for a full description of the SignalTap II Trigger Flow Description Language. You can also refer to the Quartus II Help.

The State Machine description text boxes default to show one text box per state. You can optionally have the entire flow description be shown in a single text field. This option can be useful when copying and pasting a flow description from a template or an external text editor. To toggle between one window per state, or all states in one window, select the appropriate option under **State Display mode**.

### Resources Pane

The Resources pane allows you to declare Status Flags and Counters for use in the conditional expressions in the Custom Triggering Flow. Actions to decrement and increment counters or to set and clear status flags are performed within the triggering flow that you define.

You can set up to 20 counters and 20 status flags for use. Counter and status flags values may be initialized by right-clicking the status flag or counter name after selecting a number of them from the respective drop-down list, and selecting **Set Initial Value**. Counter width can be set by right-clicking the counter name and selecting **Set Width**.

**Runtime Reconfigurability**—The **configurable at runtime** options in the Resources pane allows you to configure the custom-flow control options that can be changed at runtime without requiring a recompilation.

Table 13–6 contains a description of options that can be reconfigured at runtime.

<b>Setting</b>	<b>Description</b>
Destination of goto action	Allows you to modify the destination of the state transition at runtime.
Comparison values	Allows comparison values in Boolean expressions to be modifiable at runtime. In addition, it allows the <code>segment_trigger</code> and trigger action post-fill count argument to be modifiable at runtime.
Comparison operators	Allows comparison operators in Boolean expressions to be modifiable at runtime.
Logical operators	Allows the logical operators in Boolean expressions to be modifiable at runtime.

You can restrict changes to your SignalTap configuration to include only the options that do not require a recompilation by using the pull-down menu above the trigger list in the **Setup** tab. The option **Allow trigger condition changes only** restricts changes to only the configuration settings that the runtime configurable option set. You can then modify Trigger Flow conditions in the **Custom Trigger Flow** tab by clicking the desired parameter in the text box, and selecting a new parameter from the menu that appears.

The runtime configurable settings for the **Custom Trigger Flow** tab are on by default. You may get some performance advantages by disabling some of the runtime configurable options. Refer to “[Performance and Resource Considerations](#)” on page 13–55 for details about the effects of turning off the runtime modifiable options.

### **SignalTap II Trigger Flow Description Language**

The Trigger Flow Description Language is based on a list of conditional expressions per state to define a set of actions. Each line in [Example 13–1](#) shows a language format. Keywords are shown in bold. Non-terminals are delimited by “<>” and are further explained in the following sections. Optional arguments are delimited by “[]”.

Examples of Triggering Flow descriptions for common scenarios using the Signal Tap II Custom Triggering Flow are provided in the section, “[Custom Triggering Flow Application Examples](#)” on page 13–77.

**Example 13–1. Trigger Flow Description Language Format** *Note (1)*

```
state <State_label>:
<action_list>
```

or

```
state <State_label>:
if ( <Boolean_expression> )
<action_list>
[else if ( <boolean_expression> )
  <action_list>] (1)
[else
  <action_list>]
```

**Notes to Example 13–1:**

(1) Multiple `else if` conditions are allowed.

The priority for evaluation of conditional statements is assigned from top to bottom. The `<boolean_expression>` in an `if` statement can contain a single event, or it can contain multiple event conditions. The `action_list` embedded within an `if` or an `else if` clause must be delimited by the `begin` and `end` tokens when the action list contains multiple statements. When the boolean expression is evaluated true, the logic analyzer analyzes all of the commands in the action list concurrently. The possible actions include:

- Triggering the acquisition buffer
- Manipulating a counter or status flag resource
- Defining a state transition

**State Labels**

State Labels are identifiers that can be used in the action `goto`.

`state <state_label>`: begins the description of the actions evaluated when this state is reached.

The description of a state ends with the beginning of another state or the end of the whole trigger flow description.

**Boolean\_expression**

`Boolean_expression` is a collection of logical operators, relational operators, and their operands that evaluate into a Boolean result. Depending on the operator, the operand can be a reference to a trigger condition, a counter and a register, or a numeric value. Within an expression, parentheses can be used to group a set of operands.

**Logical operators** accept any boolean expression as an operand. The supported Logical operators are shown in [Table 13-7](#).

<b>Table 13-7. Logical Operators</b>		
<b>Operator</b>	<b>Description</b>	<b>Syntax</b>
!	NOT operator	! expr1
&&	AND operator	expr1 && expr2
	OR operator	expr1    expr2

**Relational operators** are performed on counters or status flags. The comparison value—the right operator—must be a numerical value. The supported Relational operators are shown in [Table 13-8](#).

<b>Table 13-8. Relational Operators</b>		
<b>Operator</b>	<b>Description</b>	<b>Syntax <i>Notes (1) (2)</i></b>
>	Greater than	<identifier> > <numerical_value>
>=	Greater than or Equal to	<identifier> >= <numerical_value>
==	Equals	<identifier> == <numerical_value>
!=	Does not equal	<identifier> != <numerical_value>
<=	Less than or equal to	<identifier> <= <numerical_value>
<	Less than	<identifier> < <numerical_value>

**Notes to Table 13-8:**

- (1) <identifier> indicates a counter or status flag
- (2) <numerical\_value> indicates an integer

### **Action\_list**

**Action\_list** is a list of actions that can be performed when a state is reached and a condition is also satisfied. If more than one action is specified, they must be enclosed by `begin` and `end`. The actions can be categorized as resource manipulation actions, buffer control actions and state transition actions. Actions must be embedded within a condition statement if condition statements are used in a state. Each action is terminated by a semicolon.

### Resource Manipulation Action

The resources used in the trigger flow description can be either counters or status flags. Table 13–9 shows the description and syntax of each action.

Action	Description	Syntax
Increment	Increments a counter resource by 1	<code>increment &lt;counter_identifier&gt;;</code>
Decrement	Decrements a counter resource by 1	<code>decrement &lt;counter_identifier&gt;;</code>
Reset	Resets counter resource to initial value	<code>reset &lt;counter_identifier&gt;;</code>
Set	Sets a status Flag to 1	<code>set &lt;register_flag_identifier&gt;;</code>
Clear	Sets a status Flag to 0	<code>clear &lt;register_flag_identifier&gt;;</code>

### Buffer Control Action

Buffer control actions specify an action to control the acquisition buffer. Table 13–10 shows the description and syntax of each action,

Action	Description	Syntax
trigger	Stops the acquisition for the current buffer and ends analysis. This command is required in every flow definition.	<code>trigger &lt;post-fill_count&gt;;</code>
segment_trigger	Ends the acquisition of the current segment. The Signal Tap II Logic Analyzer starts acquiring from the next segment upon evaluating this command. If all segments are filled, the oldest segment is overwritten with the latest sample. The acquisition stops when a trigger action is evaluated. This action cannot be used in non-segmented acquisition mode.	<code>segment_trigger &lt;post-fill_count&gt;;</code>

Both `trigger` and `segment_trigger` actions accept an optional post-fill count argument. If provided, the current acquisition acquires the number of samples provided by post-fill count and then stops acquisition. If no post-count value is specified, the trigger position for the affected buffer defaults to the trigger position specified in the setup tab.

Note that in the case of `segment_trigger`, acquisition of the current buffer stops immediately if a subsequent triggering action is issued in the next state, regardless of whether or not the post-fill count has been satisfied for the current buffer. The remaining unfilled post-count acquisitions in the current buffer are discarded and displayed as grayed-out samples in the data window.

### State Transition Action

State transition action specifies the next state in the custom state control flow. It is specified by the `goto` command. The syntax is as follows:

```
goto <state_label>;
```

### Specifying the Trigger Position

The SignalTap II Logic Analyzer allows you to specify the amount of data that is acquired before and after a trigger event. You can set the trigger position independently between a Runtime and Power-Up Trigger. Select the desired ratio of pre-trigger data to post-trigger data by choosing one of the following ratios:

- **Pre**—This selection saves signal activity that occurred after the trigger (12% pre-trigger, 88% post-trigger).
- **Center**—This selection saves 50% pre-trigger and 50% post-trigger data.
- **Post**—This selection saves signal activity that occurred before the trigger (88% pre-trigger, 12% post-trigger).

These pre-defined ratios apply to both circular buffers and segmented buffers.

If you use the custom-state based triggering flow, you can specify a custom trigger position. The `segment_trigger` and `trigger` actions accept a post-fill count argument. The post-fill count specifies the number of samples to capture before stopping data acquisition for the circular buffer or a data segment when using the `trigger` and `segment_trigger` commands, respectively. When the captured data is displayed in the SignalTap II data window, the trigger position appears as the number of post-count samples from the end of the acquisition segment or buffer. Refer to [Equation 1](#):

$$(1) \text{ Sample Number of Trigger Position} = (N - \text{Post-Fill Count})$$

In this case,  $N$  is the sample depth of either the acquisition segment or circular buffer.

For segmented buffers, the acquisition segments that have a post-count argument defined use the post-count setting. Segments that do not have a post-count setting default to the trigger position ratios defined in the **Setup** tab.

For more details about the Custom-State based triggering flow, refer to [“Custom State-Based Triggering” on page 13–36](#).

## Creating a Power-Up Trigger

Typically, the SignalTap II Logic Analyzer is used to trigger on events that occur during normal device operation. You start an analysis manually once the target device is fully powered on and the device’s JTAG connection is available. However, there may be cases when you would like to capture trigger events that occur during device initialization immediately after the FPGA is powered on or reset. With the SignalTap II Power-Up Trigger feature, you can capture data from triggers that occur after device programming but before the logic analyzer is started manually.

### *Enabling a Power-Up Trigger*

A different Power-Up Trigger can be added to each logic analyzer instance in the SignalTap II Instance Manager. To enable the Power-Up Trigger for a logic analyzer instance, right-click the instance, and click **Enable Power-Up Trigger**, or select the instance, and on the Edit menu, click **Enable Power-Up Trigger**. To disable a Power-Up Trigger, click **Disable Power-Up Trigger** in the same locations. **Power-Up Trigger** is shown as a child instance below the name of the selected instance with the default trigger conditions set in the node list. [Figure 13–20](#) shows the SignalTap II Editor when a Power-Up Trigger is enabled.

**Figure 13–20. SignalTap II Editor with Power-Up Trigger Enabled**

### Managing and Configuring Power-Up and Runtime Trigger Conditions

When the Power-Up Trigger is enabled for a logic analyzer instance, you create basic and advanced trigger conditions for it in the same way you do with the regular trigger, also called the Runtime Trigger. Power-Up Trigger conditions that you can adjust are color coded light blue, while Run-Time Trigger conditions remain white. Since each instance now has two sets of trigger conditions, the Power-Up Trigger and the Run-Time Trigger, you can differentiate between the two with the color coding. To switch between the trigger conditions of the Power-Up Trigger and the Runtime Trigger, double-click the instance name or the Power-Up Trigger name in the Instance Manager.

You cannot make changes to the Power-Up Trigger conditions that would normally require a full recompile with Runtime Trigger conditions, such as adding signals, deleting signals, or changing between basic and advanced triggers. For these changes to be applied to the Power-up Trigger conditions, you must first make the changes using the Runtime Trigger conditions.

Any change made to the Power-Up Trigger conditions requires that the SignalTap II Logic Analyzer be recompiled, even if a similar change to the Runtime Trigger conditions does not require a recompilation.

While creating or making changes to the trigger conditions for the Run-Time Trigger or the Power-Up Trigger, you may want to copy these conditions to the other trigger. This makes it easy to look for the same trigger during both power-up and runtime. To do this, right-click the instance name or the Power-Up Trigger name in the Instance Manager, and click **Duplicate Trigger**, or select the instance name or the Power-Up Trigger name and, on the Edit menu, click **Duplicate Trigger**.

For information about running the SignalTap II Logic Analyzer instance with a Power-Up Trigger enabled, refer to [“Running with a Power-Up Trigger” on page 13–60](#).

## Using External Triggers

You can create a trigger input that allows you to trigger the SignalTap II Logic Analyzer from an external source. The external trigger input behaves like trigger condition 1. It is evaluated and must be true before any other configured trigger conditions are evaluated. The analyzer can also supply a signal to trigger external devices or other SignalTap II instances. These features allow you to synchronize external logic analysis equipment with the internal logic analyzer. Power-Up Triggers can use the external triggers feature, but they must use the same source or target signal as their associated Run-Time Trigger.

### *Trigger In*

To use Trigger In, perform the following steps:

1. In the SignalTap II Editor, click the **Setup** tab.
2. If a Power-Up Trigger is enabled, make sure you are viewing the Runtime Trigger conditions.
3. In the **Signal Configuration** pane, turn on **Trigger In**.
4. In the **Pattern** list, select the condition you want to act as your trigger event. You can set this separately for a Runtime or a Power-Up Trigger.
5. Click **Browse** next to the **Source** field in the Trigger In pane ([Figure 13–22 on page 13–50](#)). The **Node Finder** dialog box appears.

6. In the **Node Finder** dialog box, select the signal (either an input pin or an internal signal) that you want to drive the Trigger In source, and click **OK**.

If you type a new signal name in the **Source** field, you create a new node that you can assign to an input pin in the Pin Planner or Assignment editor. If you leave the **Source** field blank, a default name is entered in the form `auto_stp_trigger_in_<SignalTap instance number>`.

### *Trigger Out*

To use Trigger Out, perform the following steps:

1. In the SignalTap II Editor, click the **Setup** tab.
2. If a Power-Up trigger is enabled, make sure you are viewing the Runtime Trigger conditions.
3. In the **Signal Configuration** pane, turn on **Trigger Out** (refer to [Figure 13–21 on page 13–49](#))
4. In the **Level** list, select the condition you want to signify that the trigger event is occurring. You can set this separately for a Run-Time or a Power-Up Trigger.
5. Type a new signal name in the **Target** field. A new node name is created that you must assign to an output pin in the Pin Planner or Assignment editor.

If you leave the **Target** field blank, a default name is entered in the form `auto_stp_trigger_out_<SignalTap instance number>`.  
When the logic analyzer triggers, a signal at the level you indicated will be output on the pin you assigned to the new node.

### *Using the Trigger Out of One Analyzer as the Trigger In of Another Analyzer*

An advanced feature of the SignalTap II Logic Analyzer is the ability to use the Trigger Out of one analyzer as the Trigger In to another analyzer. This feature allows you to synchronize and debug events that occur across multiple clock domains.

To perform this operation, first enable the **Trigger Out** of the source logic analyzer instance. On the Trigger out **Target** list, select the targeted logic analyzer instance. For example, if the instance named `auto_sigaltap_0` should trigger `auto_sigaltap_1`, select `auto_sigaltap_1|trigger_in` from the list (Figure 13–21).

**Figure 13–21. Configuring the Trigger Out Signal**

- This automatically enables the Trigger In of the targeted logic analyzer instance and fills in the Trigger In **Source** field with the Trigger Out signal from the source logic analyzer instance. In this example, `auto_sigaltap_0` is targeting `auto_sigaltap_1`. The Trigger In **Source** field of `auto_sigaltap_1` is automatically filled in with `auto_sigaltap_0|trigger_out` (Figure 13–22).

Figure 13–22. Configuring the Trigger In Signal

## Compile the Design

When you add a SignalTap II file to your project, the SignalTap II Logic Analyzer becomes part of your design. You must compile your project to incorporate the SignalTap II logic and enable the JTAG connection that is used to control the logic analyzer. When you are debugging with a traditional external logic analyzer, it is often necessary to make changes to the signals monitored as well as the trigger conditions. Since these adjustments often translate into recompilation time when using the SignalTap II Logic Analyzer, you can use the SignalTap II Logic Analyzer feature along with incremental compilation in the Quartus II software to reduce time spent recompiling.

## Faster Compilations with Quartus II Incremental Compilation

To use Incremental compilation with the SignalTap II Logic Analyzer, you must perform the following steps:

- Enable Full Incremental Compilation for your design
- Assign design partitions
- Set partitions to the proper preservation levels
- Enable SignalTap for your design
- Add signals to SignalTap using the appropriate netlist filter in the node finder (either SignalTap II: pre-synthesis or SignalTap II: post-fitting).

When you compile your design with a SignalTap II file, the `sld_signaltap` and `sld_hub` entities are automatically added to the compilation hierarchy. These two entities are the main components of the SignalTap II Logic Analyzer, providing the trigger logic and JTAG interface required for operation.

Incremental compilation enables you to preserve the synthesis and fitting results of your original design and add the SignalTap II Logic Analyzer to your design without recompiling your original source code. This feature is also useful when you want to modify the configuration of the SignalTap II file. For example, you can modify the buffer sample depth or memory type without performing a full compilation after the change is made. Only the SignalTap II Logic Analyzer, configured as its own design partition, must be recompiled to reflect the changes.

To use incremental compilation, you must first enable **Full Incremental Compilation** for your design if it is not already enabled, assign design partitions if necessary, and set the design partitions to the correct preservation levels. Incremental compilation is the default setting for new projects in the Quartus II software, so you can establish design partitions immediately in a new project. However, it is not necessary to create any design partitions to use the SignalTap II Incremental Compilation feature. Once your design is set up to use full incremental compilation, the SignalTap II Logic Analyzer acts as its own separate design partition. You can begin taking advantage of incremental compilation by using the **SignalTap II: post-fitting filter** in the **Node Finder** to add signals for logic analysis.

### *Enabling Incremental Compilation for your Design*

To enable Incremental Compilation if it is not already enabled, perform the following steps:

1. On the Assignments menu, click **Design Partitions window**.

2. In the **Incremental Compilation** list, select **Full Incremental Compilation**.
3. Create user-defined partitions if desired and set the **Netlist Type** to **Post-fit** for all partitions.

The netlist type for the top-level partition defaults to source. To take advantage of incremental compilation, you must set the Netlist types for the partitions you wish to tap as post-fit.

4. On the Processing menu, click **Start Compilation**, or click **Start Compilation** on the toolbar.

Your project is fully compiled the first time, establishing the design partitions you have created. When enabled for your design, the SignalTap II Logic Analyzer will always be a separate partition. After the first compilation, you can use the SignalTap II Logic Analyzer to analyze signals from the post-fit netlist. If your partitions are set correctly, subsequent compilations due to SignalTap II settings are able to take advantage of the shorter compilation times.

For more information about configuring and performing Incremental Compilation, refer to the *Quartus II Incremental Compilation for Hierarchical and Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

### *Using Incremental Compilation with the SignalTap II Logic Analyzer*

The SignalTap II Logic Analyzer is automatically configured to work with the incremental compilation flow. For all signals that you want to connect to the SignalTap II Logic Analyzer from the post-fit netlist, set the netlist type of the partition containing the desired signals to Post-Fit or Post-Fit (Strict) with a Fitter Preservation Level of Placement and Routing using the Design Partitions window. Use the **SignalTap II: post-fitting filter** in the **Node Finder** to add the signals of interest to your SignalTap II configuration file. If you want to add signals from the pre-synthesis netlist, set the netlist type to Source File and use the **SignalTap II: pre-synthesis filter** in the **Node Finder**. Do not use the netlist type **Post-Synthesis** with the SignalTap II Logic Analyzer.

Be sure to conform to the following guidelines when using post-fit/pre-synthesis nodes:

- Read all incremental compilation guidelines to ensure the proper partition of a project.
- To speed compile time, use only post-fit nodes for partitions set to preservation level post-fit.

- Do not mix pre-synthesis and post-fit nodes in any partition. If you must tap presynthesis nodes for a particular partition, make all tapped nodes in that partition presynthesis nodes and change the netlist type to **source** in the design partitions window.

Node names may be different between a pre-synthesis netlist and a post-fit netlist. In general, registers and user input signals share common names between the two netlists. During compilation, certain optimizations will change the names of combinational signals in your RTL. If the type of node name chosen does not match the netlist type, the compiler may not be able to find the signal to connect to your SignalTap II Logic Analyzer instance for analysis. The compiler will issue a critical warning to warn you of this scenario. The signal that is not connected is tied to ground in the SignalTap II data tab.

If you do use incremental compile flow with the SignalTap II Logic Analyzer and source file changes are necessary, be aware that you may have to remove compiler-generated post-fit net names. Source code changes force the affected partition to go through a resynthesis. During synthesis, the compiler cannot find compiler-generated net names from a previous compilation. Altera recommends you use only registered and user input signals as debugging taps in your STP file whenever possible. Both registered and user-supplied input signals share common node names in the pre-synthesis and post-fit netlist. As a result, using only registered and user-supplied input signals in your STP file limits the changes you need to make to your SignalTap configuration.

To verify that your original design was not modified, examine the messages in the **Partition Merge** section of the Compilation Report. [Figure 13–23](#) shows an example of the messages displayed.

Figure 13–23. Compilation Report Messages

Unless you make changes to your design partitions that require recompilation, only the SignalTap II design partition is recompiled. If you make subsequent changes to only the SignalTap II file, only the SignalTap II design partition must be recompiled, reducing your recompilation time.

## Preventing Changes Requiring Recompilation

You can configure the SignalTap II file to prevent changes that normally require a recompilation. You do this by selecting a lock mode from above the node list in the **Setup** tab. Whether or not you are using incremental compilation, you can lock your configuration by choosing to allow only trigger condition changes.

For more information about the use of lock modes, refer to the Quartus II Help.

## Timing Preservation with the SignalTap II Logic Analyzer

In addition to verifying functionality, timing closure is one of the most crucial processes in successfully completing a design. When you compile a project with a SignalTap II Logic Analyzer without the use of incremental compilation, you add IP to your existing design. Therefore, you can affect the existing placement, routing, and timing of your design. To minimize the effect that the SignalTap II Logic Analyzer has on your design, Altera recommends that you use incremental compilation for

your project. Incremental compilation is the default setting in new designs and can be easily enabled and configured in existing designs. With the SignalTap II Logic Analyzer in its own design partition, it has little to no affect on your design.

In addition to using the incremental compilation flow for your design, you can use the following techniques to help maintain timing:

- Avoid adding critical path signals to your SignalTap II file.
- Minimize the number of combinational signals you add to your SignalTap II file, and add registers whenever possible.
- Specify an  $f_{MAX}$  constraint for each clock in your design.

For an example of timing preservation with the SignalTap II Logic Analyzer, refer to the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

## Performance and Resource Considerations

There is an inherent trade-off between runtime flexibility of the SignalTap II Logic Analyzer, timing performance of the Signal Tap II Logic Analyzer, and the resource usage. The SignalTap II Logic Analyzer allows you to select the runtime configurable parameters to balance the need for runtime flexibility, speed, and area. The default values have been chosen to provide maximum flexibility so you can reach debugging closure as quickly as possible; however, you can adjust these settings to determine whether there is a more optimal configuration for your design.

The suggestions in this section provide some tips to provide extra timing slack if you have determined that the SignalTap II logic is in your critical path, or to alleviate the resource requirements that the SignalTap II Logic Analyzer consumes if your design is resource-constrained.

If the SignalTap II logic is part of your critical path, the following suggestions can help to speed up the performance of the SignalTap II Logic Analyzer:

- **Disable runtime configurable options**—Certain resources are allocated to accommodate for run-time flexibility. If you are using either advanced triggers or the state-based triggering flow, you can disable run-time configurable parameters for a boost in  $f_{MAX}$  of the SignalTap II logic. If you are using the state-based triggering flow, try disabling the **Goto state destination** option and performing a recompilation before disabling the other runtime configurable options. The **Goto state destination** option has the greatest impact on  $f_{MAX}$  as compared to the other runtime configurable options.

- **Minimize the number of signals that have Trigger Enable selected**—All of the signals that you add to the SignalTap II file have Trigger Enable turned on. Turn off Trigger Enable for signals that you do not plan to use as triggers.
- **Turn on Physical Synthesis for register retiming**—If you have a large number of triggering signals enabled (greater than the number of inputs that would fit in a LAB) that fan-in to logic gate-based triggering condition, such as a basic trigger condition or a logical reduction operator in the advanced trigger tab, turn on the **Perform register retiming**. This can help balance combinational logic across LABs.

If your design is resource constrained, the following suggestions can help to reduce the amount of logic or memory used by the SignalTap II Logic Analyzer:

- **Disable runtime configurable options**—Disabling runtime configurability for the advanced trigger conditions or the runtime configurable options in the state-based triggering flow will result in less LE usage.
- **Minimize the number of segments in the acquisition buffer**—You can reduce the number of logic resources used for the SignalTap II Logic Analyzer by limiting the number of segments in your sampling buffer to only that which is required.
- **Disable the Data Enable for signals that are used for triggering only**—By default, both the data enable and trigger enable options are selected for all signals. Turning off the data enable option for signals used as trigger inputs only will save on memory resources used by the SignalTap II Logic Analyzer.

Because performance results are design-dependent, try these options in different combinations until you achieve the desired balance between functionality, performance, and utilization.

For more information about area and timing optimization, refer the *Area and Timing Optimization* chapter in volume 2 of the *Quartus II Handbook*.

## Program the Target Device or Devices

Once your project, including the SignalTap II Logic Analyzer, is compiled, you must configure the FPGA target device. When you are using the SignalTap II Logic Analyzer for debugging, you can configure the device from the SignalTap II file instead of the Quartus II Programmer. Because you configure from the SignalTap II file, you can open more than one SignalTap II file and program multiple devices to debug multiple designs simultaneously.

The settings in a SignalTap II file must be compatible with the programming (SOF) file used to program the device. A SignalTap II file is considered compatible with an SOF when the settings for the logic analyzer, such as the size of the capture buffer and the signals selected for monitoring or triggering, match the way the target device will be programmed. If the files are not compatible, you will still be able to program the device, but you will not be able to run or control the logic analyzer from the SignalTap II Editor.

To ensure programming compatibility, make sure to program your device with the latest SOF created from the most recent compilation.

Before starting a debugging session, do not make any changes to the SignalTap II file settings that would require the project to be recompiled. You can check the SignalTap II status display at the top of the Instance Manager to see if a change you made requires the design to be recompiled, producing a new SOF. This gives you the opportunity to undo the change, so that a recompilation is not necessary. To prevent any such changes, enable a lock mode in the SignalTap II file.

### Programming a Single Device

To configure a single device for use with the SignalTap II Logic Analyzer, perform the follow steps:

1. In the **JTAG Chain Configuration** pane in the SignalTap II Editor, select the connection you use to communicate with the device from the **Hardware** list. If you need to add your communication cable to the list, click **Setup** to configure your connection.
2. Click **Browse** in the **JTAG Chain Configuration** pane, and select the SOF file that includes the compatible SignalTap II Logic Analyzer.
3. Click **Scan Chain**. The Scan Chain operation enumerates all of the JTAG devices within your JTAG chain.

- In the **Device** list, select the device to which you want to download the design. The device list shows an ordered list of all devices in the JTAG chain.

All of the devices are numbered sequentially according to their position in the JTAG chain, prefixed with the “@”. For example:  
 @1 : EP3C25 (0x020F30DD) lists a Cyclone III device as the first device in the chain, with the JTAG ID code of 0x020F30DD.

- Click the **Program Device** icon.

## Programming Multiple Devices to Debug Multiple Designs

You can simultaneously debug multiple designs using one instance of the Quartus II software by performing the following steps:

- Create, configure, and compile each project that includes a SignalTap II file.
- Open each SignalTap II file.

You do not have to open a Quartus II project to open a SignalTap II file.

- Use the **JTAG Chain Configuration** pane controls to select the target device in each SignalTap II file.
- Program each FPGA.
- Run each analyzer independently.

Figure 13–24 shows a JTAG chain and its associated SignalTap II files.

**Figure 13–24. JTAG Chain**

## Run the SignalTap II Logic Analyzer

After the device is configured with your design that includes the SignalTap II Logic Analyzer, you can perform debugging operations in a manner similar to the use of an external logic analyzer. You “arm” the logic analyzer by starting an analysis. When your trigger event occurs, the captured data is stored in the memory buffer on the device and then transferred to the SignalTap II file over the JTAG connection. You can also perform the equivalent of a “force trigger” that lets you view the captured data currently in the buffer without a trigger event occurring. Figure 13–25 illustrates a flow that shows how you operate the SignalTap II Logic Analyzer. The flowchart indicates where Power-Up and Run-Time Trigger events occur and when captured data from these events is available for analysis.

**Figure 13–25. Power-Up and runtime Trigger Events Flowchart**

The SignalTap II toolbar in the Instance Manager has four options for running the analyzer:

- **Run Analysis**—The SignalTap II Logic Analyzer runs until the trigger event occurs. When the trigger event occurs, monitoring and data capture stops once the acquisition buffer is full.
- **AutoRun Analysis**—The SignalTap II Logic Analyzer continuously captures data until the **Stop Analysis** button is clicked, ignoring all trigger event conditions.
- **Stop Analysis**—SignalTap II analysis stops. The acquired data does not appear automatically if the trigger event has not occurred.
- **Read Data**—Captured data is displayed. This button is useful if you want to view the acquired data even if the trigger has not occurred.

### Running with a Power-Up Trigger

If you have enabled and set up a Power-Up Trigger for an instance of the SignalTap II Logic Analyzer, the captured data may already be available for viewing if the trigger event occurred after device configuration. To download the captured data or to check if the Power-Up Trigger is still running, click **Run Analysis** in the Instance Manager. If the Power-Up Trigger occurred, the logic analyzer immediately stops, and the captured data is downloaded from the device. The data can now be viewed on the **Data** tab of the SignalTap II Editor. If the Power-Up Trigger did not occur, no captured data is downloaded, and the logic analyzer continues to run. You can wait for the Power-Up Trigger event to occur, or, to stop the logic analyzer, click **Stop Analysis**.

### Running with Runtime Triggers

You can arm and run the SignalTap II Logic Analyzer manually after device configuration to capture data samples based on the Runtime Trigger. You can do this immediately if there is no Power-Up Trigger enabled. If a Power-Up Trigger is enabled, you can do this after the Power-Up Trigger data is downloaded from the device or once the logic analyzer is stopped because the Power-Up Trigger event did not occur. Click **Run Analysis** in the SignalTap II Editor to start monitoring for the trigger event. You can start multiple SignalTap II instances at the same time by selecting all of the required instances before you click **Run Analysis** on the toolbar.

Unless the logic analyzer is stopped manually, data capture begins when the trigger event evaluates to `TRUE`. When this happens, the captured data is downloaded from the buffer. You can view the data in the **Data** tab of the SignalTap II Editor.

## Performing a Force Trigger

Sometimes when you use an external logic analyzer or oscilloscope, you want to see the current state of signals without setting up or waiting for a trigger event to occur. This is referred to as a “force trigger” operation, because you are forcing the test equipment to capture data without regard to any set trigger conditions. With the SignalTap II Logic Analyzer, you can choose to run the analyzer and capture data immediately or run the analyzer and capture data when you want.

For more information, refer to the *Design Debugging Using In-System Sources and Probes* chapter in volume 3 of the *Quartus II Handbook*.

To run the analyzer and immediately capture data, disable the trigger conditions by turning off each **Trigger Condition** column in the node list. This operation does not require a recompilation. Click **Run Analysis** in the Instance Manager. The SignalTap II Logic Analyzer immediately triggers, captures, and downloads the data to the **Data** tab of the SignalTap II Editor. If the data does not download automatically, click **Read Data** in the Instance Manager.

If you want to choose when to capture data manually, it is not required that you disable the trigger conditions. Click **Autorun Analysis** to start the logic analyzer, and click **Stop Analysis** to capture data. If the data does not download to the **Data** tab of the SignalTap II Editor automatically, click **Read Data**.

Finally, you can choose to capture data manually after a trigger event has occurred. This is useful if you still want the trigger event to occur, but you want to capture data about the signals at some point after the trigger without capturing the trigger event itself. To do this, set the **Buffer acquisition mode** to **Circular** and **Continuous**, and click **Run Analysis**. When the trigger event occurs, the status in the SignalTap II Health Monitor is shown as *Acquiring post-trigger data*, but the logic analyzer does not stop. When you want to capture and download the data, click **Stop Analysis**. If the data does not download automatically, click **Read Data**.

You can also use In-System Sources and Probes in conjunction with the SignalTap II Logic Analyzer to force trigger conditions. The In-System Sources and Probes feature allows you to drive and sample values on to selected nets over the JTAG chain. For more information, refer to the *Design Debugging Using In-System Sources and Probes* chapter in volume 3 of the *Quartus II Handbook*.

## SignalTap II Status Messages

Table 13–11 describes the text messages that may appear in the SignalTap II Health Monitor in the Instance Manager before, during, and after a data acquisition. Use these messages to know the state of the logic analyzer or what operation it is performing.

<b>Message</b>	<b>Message Description</b>
Not running	The SignalTap II Logic Analyzer is not running. There is no connection to a device or the device is not configured.
(Power-Up Trigger) Waiting for clock (1)	The SignalTap II Logic Analyzer is performing a Runtime or Power-Up Trigger acquisition and is waiting for the clock signal to transition.
Acquiring (Power-Up) pre-trigger data (1)	The trigger condition has not been evaluated yet. A full buffer of data is collected if the circular buffer acquisition mode is selected.
Trigger In conditions met	Trigger In condition has occurred. The SignalTap II Logic Analyzer is waiting for the condition of the first trigger condition to occur. This can appear if Trigger In is specified.
Waiting for (Power-up) trigger (1)	The SignalTap II Logic Analyzer is now waiting for the trigger event to occur.
Trigger level <x> met	The condition of trigger condition x has occurred. The SignalTap II Logic Analyzer is waiting for the condition specified in condition x + 1 to occur.
Acquiring (power-up) post-trigger data (1)	The whole trigger event has occurred. The SignalTap II Logic Analyzer is acquiring the post-trigger data. The amount of post-trigger data collected is user-defined between 12%, 50%, and 88% when the circular buffer acquisition mode is selected.
Offload acquired (Power-Up) data (1)	Data is being transmitted to the Quartus II software through the JTAG chain.
Ready to acquire	The SignalTap II Logic Analyzer is waiting for the user to arm the analyzer.

**Note to Table 13–11:**

- (1) This message can appear for both Runtime and Power-Up Trigger events. When referring to a Power-Up Trigger, the text in parentheses is added.

In segmented acquisition mode, pre-trigger and post-trigger do not apply.

## View, Analyze, and Use Captured Data

Once a trigger event has occurred or you capture data manually, you can use the SignalTap II interface to examine the data, and use your findings to help debug your design. The SignalTap II Logic Analyzer provides a number of features that makes it easy to do this.

### Viewing Captured Data

You can view captured SignalTap II data in the **Data** tab of the SignalTap II file (Figure 13–26). Each row of the **Data** tab displays the captured data for one signal or bus. Buses can be expanded to show the data for each individual signal on the bus. Click on the data waveforms to zoom in on the captured data samples, and right-click to zoom out.

**Figure 13–26. Captured SignalTap II Data**

When you are viewing captured data, it is often useful to know the time interval between two events. Time bars enable you to see the number of clock cycles between two samples of captured data in your system. There are two types of time bars:

- **Master Time Bar**—The master time bar's label displays the absolute time of its location in bold. The master time bar is a thick black line in the **Data** tab. The captured data has only one master time bar.
- **Reference Time Bar**—The reference time bar's label displays the time relative to the master time bar. You can create an unlimited number of reference time bars.

To help you find a transition of signals relative to the master time bar location, use either the **Next Transition** or the **Previous Transition** button. This aligns the master time bar with the next or previous

transition of a selected signal or group of selected signals. This feature is very useful when the sample depth is very large and the rate at which signals toggle is very low.

## Creating Mnemonics for Bit Patterns

The mnemonic table feature allows you to assign a meaningful name to a set of bit patterns, such as a bus. To create a mnemonic table, right-click in the **Setup** or **Data** tab of a SignalTap II file, and click **Mnemonic Table Setup**. You create a mnemonic table by entering sets of bit patterns and specifying a label to represent each pattern. Once you have created a mnemonic table, you assign it to a group of signals. To assign a mnemonic table, right-click on the group, click **Bus Display Format**, and select the desired mnemonic table.

The labels you create in a table are used in different ways on the **Setup** and **Data** tabs. On the **Setup** tab, you can create basic triggers with meaningful names by right-clicking an entry in any Trigger Conditions column and selecting a label from the table you assigned to the signal group. On the **Data** tab, if any captured data matches a bit pattern contained in an assigned mnemonic table, the signal group data is replaced with the appropriate label, making it easy to see when expected data patterns occur.

## Automatic Mnemonics with a Plug-In

When you use a plug-in to add signals to a SignalTap II file, mnemonic tables for the added signals are automatically created and assigned to the signals defined in the plug-in. If you ever need to manually enable these mnemonic tables, right-click on the name of the signal or signal group. On the **Bus Display Format** submenu, click the name of the mnemonic table that matches the plug-in.

As an example, the Nios II plug-in makes it easy to monitor your design's signal activity as code is executed. If you have set up the logic analyzer to trigger on a function name in your Nios II code based on data from an ELF file, you can see the function name in the Instance Address signal group at the trigger sample, along with the corresponding disassembled code in the Disassembly signal group, as shown in [Figure 13-27 on page 13-65](#). Captured data samples around the trigger are referenced as offset addresses from the trigger function name.

Figure 13–27. Data Tab when the Nios II Plug-In is Used

Type	Alias	Name	37	Value	38	48	49	50	51	52
PC		...Nios II Inst Address		alt_main+0x8		<empty>		alt_main+0xc		<empty>
DIS		...Nios II Disassembly		mov fp, sp		<empty>		movi r2, 2		<empty>

## Locating a Node in the Design

When you find the source of a bug in your design using the SignalTap II Logic Analyzer, you can use the node locate feature to locate that signal in many of the tools found in the Quartus II software, as well as in your design files. This lets you find the source of the problem quickly so you can modify your design to correct the flaw. To locate a signal from the SignalTap II Logic Analyzer in one of the Quartus II software tools or your design files, right-click on the signal in the SignalTap II file, and click **Locate in** <tool name>. You can locate a signal from the node list in any of the following locations:

- Assignment Editor
- Pin Planner
- Timing Closure Floorplan
- Chip Planner
- Resource Property Editor
- Technology Map Viewer
- RTL Viewer
- Design File

For more information about using these tools, refer to the appropriate chapters in the *Quartus II Handbook*.

## Saving Captured Data

The data log shows the history of captured data and the triggers used to capture the data. The analyzer acquires data, stores it in a log, and displays it as waveforms. When the logic analyzer is in auto-run mode and a trigger event occurs more than once, captured data for each time the trigger occurred is stored as a separate entry in the data log. This makes it easy to go back and review the captured data for each triggering event. The default name for a log is based on the time when the data was acquired. Altera recommends that you rename the data log with a more meaningful name.

The logs are organized in a hierarchical manner; similar logs of captured data are grouped together in trigger sets. If the Data Log pane is closed, on the View menu, select **Data Log** to reopen it. To enable data logging, turn on **Enable data log** in the **Data Log** (Figure 13–11). To recall a data log for a given trigger set and make it active, double-click the name of the data log in the list.

The Data Log feature is useful for organizing different sets of trigger conditions and different sets of signal configurations. Refer to “[Managing Multiple SignalTap II Files and Configurations](#)” on page 13–28.

## Converting Captured Data to Other File Formats

You can export captured data in the following file formats, some of which can be used with other EDA simulation tools:

- Comma Separated Values File (.csv)
- Table File (.tbl)
- Value Change Dump File (.vcd)
- Vector Waveform File (.vwf)
- Graphics format files (.jpg, .bmp)

To export the SignalTap II Logic Analyzer’s captured data, on the File menu, click **Export** and specify the **File Name**, the **Export Format**, and the **Clock Period**.

## Creating a SignalTap II List File

Captured data can also be viewed in a SignalTap II list file. A SignalTap II list file is a text file that lists all the data captured by the logic analyzer for a trigger event. Each row of the list file corresponds to one captured sample in the buffer. Columns correspond to the value of each of the captured signals or signal groups for that sample. If a mnemonic table was created for the captured data, the numerical values in the list are replaced with a matching entry from the table. This is especially useful with the use of a plug-in that includes instruction code disassembly. You can immediately see the order in which the instruction code was executed during the same time period of the trigger event. To create a SignalTap II list file, on the File menu, select **Create/Update**, and click **Create SignalTap II List File**.

## Other Features

The SignalTap II Logic Analyzer has a number of other features that do not necessarily belong to a particular task in the task flow.

### Using the SignalTap II MATLAB MEX Function to Capture Data

If you use MATLAB for DSP design, you can call the MATLAB MEX function `alt_signaltap_run`, built into the Quartus II software, to acquire data from the SignalTap II Logic Analyzer directly into a matrix in the MATLAB environment. If you use the MEX function repeatedly in a loop, you can perform as many acquisitions as you can when using SignalTap II in the Quartus II software environment in the same amount of time.

The SignalTap II MATLAB MEX function is available only in the Windows version of the Quartus II software. It is compatible with MATLAB Release 14 Original Release Version 7 and later.

To set up the Quartus II software and the MATLAB environment to perform SignalTap II acquisitions, perform the following steps:

1. In the Quartus II software, create a SignalTap II file.
2. In the node list in the **Data** tab of the SignalTap II Editor, organize the signals and groups of signals into the order in which you want them to appear in the MATLAB matrix. Each column of the imported matrix represents a single SignalTap II acquisition sample, while each row represents a signal or group of signals in the order they are organized in the **Data** tab.

Signal groups acquired from the SignalTap II Logic Analyzer and transferred into the MATLAB environment with the MEX function are limited to a width of 32 signals. If you want to use the MEX function with a bus or signal group that contains more than 32 signals, split the group up into smaller groups that do not exceed the 32 signal limit.

3. Save the SignalTap II file and compile your design. Program your device and run the SignalTap II Logic Analyzer to make sure your trigger conditions and signal acquisition are working correctly.
4. In the MATLAB environment, add the Quartus II binary directory to your path with the following command:

```
addpath <Quartus install directory>\win ↵
```

You can view the help file for the MEX function by entering `alt_sigtap_run` in MATLAB without any operators.

You use the MEX function in the MATLAB environment to open the JTAG connection to the device and run the SignalTap II Logic Analyzer to acquire data. When you finish acquiring data, you must close the connection.

To open the JTAG connection and begin acquiring captured data directly into a MATLAB matrix called `stp`, use the following command:

```
stp = alt_sigtap_run ('<stp filename>', ('signed'|'unsigned') [, '<instance names>'], /  
'<signalset name>', '<trigger name>']]); ↵
```

When capturing data, `<stp filename>` is the name of the SignalTap II file you want to use. This is required for using the MEX function. The other MEX function options are defined in [Table 13–12](#).

<b>Table 13–12. SignalTap II MATLAB MEX Function Options (Part 1 of 2)</b>		
<b>Option</b>	<b>Usage</b>	<b>Description</b>
signed unsigned	'signed' 'unsigned'	The <b>signed</b> option turns signal group data into 32-bit two's complement signed integers. The most significant bit (MSB) of the group as defined in the SignalTap II <b>Data</b> tab is the sign bit. The <b>unsigned</b> option keeps the data as an unsigned integer. The default is <b>signed</b> .

**Table 13–12. SignalTap II MATLAB MEX Function Options (Part 2 of 2)**

Option	Usage	Description
<instance name>	'auto_sigtap_0'	Specify a SignalTap II instance if more than one instance is defined. The default is the first instance in the SignalTap II file, auto_sigtap_0.
<signal set name> <trigger name>	'my_signalset' 'my_trigger'	Specify the signal set and trigger from the SignalTap II data log if multiple configurations are present in the SignalTap II file. The default is the active signal set and trigger in the file.

You can enable or disable verbose mode to see the status of the logic analyzer while it is acquiring data. To enable or disable verbose mode, use the following commands:

```
alt_sigtap_run('VERBOSE_ON'); ←
alt_sigtap_run('VERBOSE_OFF'); ←
```

When you finish acquiring data, you must close the JTAG connection. Use the following command to close the connection:

```
alt_sigtap_run('END_CONNECTION'); ←
```

For more information about the use of MEX functions in MATLAB, refer to the MATLAB Help.

## Using SignalTap II in a Lab Environment

You can install a stand-alone version of the SignalTap II Logic Analyzer. This version is particularly useful in a lab environment where you do not have a workstation that meets the requirements for a complete Quartus II installation, or if you do not have a license for a full installation of the Quartus II software. The stand-alone version of the SignalTap II Logic Analyzer is included with the Quartus II stand-alone Programmer and is available from the Downloads page of the Altera website, [www.altera.com](http://www.altera.com).

## Remote Debugging Using the SignalTap II Logic Analyzer

You can use the SignalTap II Logic Analyzer to debug a design that is running on a device attached to a PC in a remote location.

To perform a remote debugging session, you must have the following setup:

- The Quartus II software installed on the local PC
- Stand-alone SignalTap II Logic Analyzer or the full version of the Quartus II software installed on the remote PC
- Programming hardware connected to the device on the PCB at the remote location
- TCP/IP protocol connection

### *Equipment Setup*

On the PC in the remote location, install the stand-alone version of the SignalTap II Logic Analyzer or the full version of the Quartus II software. This remote computer must have Altera programming hardware connected, such as the EthernetBlaster or USB-Blaster.

On the local PC, install the full version of the Quartus II software. This local PC must be connected to the remote PC across a LAN with the TCP/IP protocol.

### *Software Setup on the Remote PC*

To setup the software on the remote PC, perform the following steps:

1. In the Quartus II programmer, click **Hardware Setup**.
2. Click the **JTAG Settings** tab (Figure 13–28 on page 13–70).

---

**Figure 13–28. Configure JTAG on Remote PC**

3. Click **Configure local JTAG Server**.
4. In the **Configure Local JTAG Server** dialog box (Figure 13–29), turn on **Enable remote clients to connect to the local JTAG server**, and type your password in the password box. Type your password again in the **Confirm Password** box and click **OK**.

**Figure 13–29. Configure Local JTAG Server on Remote**

### *Software Setup on the Local PC*

To set up your software on your local PC, perform the following steps:

1. Launch the Quartus II programmer.
2. Click **Hardware Setup**.
3. On the **JTAG settings** tab, click **Add server**.
4. In the **Add Server** dialog box (Figure 13–30), type the network name or IP address of the server you want to use and the password for the JTAG server that you created on the remote PC.

**Figure 13–30. Add Server Dialog Box**

5. Click **OK**.

### SignalTap II Setup on the Local PC

To connect to the hardware on the remote PC, perform the following steps:

1. Click the **Hardware Settings** tab and select the hardware on the remote PC (Figure 13–31).

**Figure 13–31. Selecting Hardware on Remote PC**

2. Click **Close**.

You can now control the logic analyzer on the device attached to the remote PC as if it was connected directly to the local PC.

## SignalTap II Scripting Support

You can run procedures and make settings described in this chapter in a Tcl script. You can also run some procedures at a command prompt. For detailed information about scripting command options, refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ←
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*.

For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## SignalTap II Command Line Options

To compile your design with the SignalTap II Logic Analyzer using the command prompt, you must use the `quartus_stp` command.

[Table 13–13](#) shows the options that help you better understand how to use the `quartus_stp` executable.

<i>Table 13–13. SignalTap II Command-Line Options (Part 1 of 2)</i>		
Option	Usage	Description
<code>stp_file</code>	<code>quartus_stp --stp_file &lt;stp_filename&gt;</code>	Assigns the specified SignalTap II file to the <code>USE_SIGNALTAP_FILE</code> in the Quartus II Settings File (QSF).
<code>enable</code>	<code>quartus_stp --enable</code>	Creates assignments to the specified SignalTap II file in the QSF, and changes <code>ENABLE_SIGNALTAP</code> to ON. The SignalTap II Logic Analyzer is included in your design the next time the project is compiled. If no SignalTap II file is specified in the QSF, the <code>--stp_file</code> option must be used. If the <code>--enable</code> option is omitted, the current value of <code>ENABLE_SIGNALTAP</code> in the QSF is used.

<i>Table 13–13. SignalTap II Command-Line Options (Part 2 of 2)</i>		
Option	Usage	Description
disable	<code>quartus_stp --disable</code>	Removes the SignalTap II file reference from the QSF and changes <code>ENABLE_SIGNALTAP</code> to <code>OFF</code> . The SignalTap II Logic Analyzer is removed from the design database the next time you compile your design. If the <code>--disable</code> option is omitted, the current value of <code>ENABLE_SIGNALTAP</code> in the QSF is used.
<code>create_signaltap_hdl_file</code>	<code>quartus_stp --create_signaltap_hdl_file</code>	Creates a SignalTap II file representing the SignalTap II instance in the design generated by the SignalTap II Logic Analyzer megafunction created with the MegaWizard Plug-in Manager. The file is based on the last compilation. You must use the <code>--stp_file</code> option to properly create a SignalTap II file. Analogous to <b>Create SignalTap II File from Design Instance(s)</b> command in the Quartus II software.

**Example 13–2** illustrates how to compile a design with the SignalTap II Logic Analyzer at the command line:

**Example 13–2.**

```
quartus_stp filtref --stp_file stp1.stp --enable ↵
quartus_map filtref --source=filtref.bdf --family=CYCLONE ↵
quartus_fit filtref --part=EP1C12Q240C6 --fmax=80MHz --tsu=8ns ↵
quartus_tan filtref ↵
quartus_asm filtref ↵
```

The `quartus_stp --stp_file stp1.stp --enable` command creates the QSF variable and instructs the Quartus II software to compile the **stp1.stp** file with your design.

Example 13–3 shows how to create a new SignalTap II file after building the SignalTap II Logic Analyzer instance with the MegaWizard Plug-In Manager:

**Example 13–3.**

```
quartus_stp filtref --create_signaltap_hdl_file --stp_file stp1.stp ←
```

For information about the other command line executables and options refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

## SignalTap II Tcl Commands

The `quartus_stp` executable supports a Tcl interface that allows you to capture data without running the Quartus II GUI. You cannot execute SignalTap II Tcl commands from within the Tcl console in the GUI. They must be run from the command line with the `quartus_stp` executable. To run a Tcl file that has SignalTap II Tcl commands, use the following command:

```
quartus_stp -t <Tcl file> ←
```

Table 13–14 shows the Tcl commands that you can use with SignalTap II.

Command	Argument	Description
open_session	-name <stp_filename>	Opens the specified SignalTap II file. All captured data is stored in this file.
run	-instance <instance_name> -signal_set <signal_set> (optional) -trigger <trigger_name> (optional) -data_log <data_log_name> (optional) -timeout <seconds> (optional)	Starts the analyzer. This command must be followed by all the required arguments to properly start the analyzer. You can optionally specify the name of the data log you want to create. If the Trigger condition is not met, you can specify a timeout value to stop the analyzer.

**Table 13–14. SignalTap II Tcl Commands (Part 2 of 2)**

Command	Argument	Description
run_multiple_start	None	Defines the start of a set of run commands. Use this command when multiple instances of data acquisition are started simultaneously. Add this command before the set of run commands that specify data acquisition. You must use this command with the run_multiple_end command. If the run_multiple_end command is not included, the run commands will not execute.
run_multiple_end	None	Defines the end of a set of run commands. Use this command when multiple instances of data acquisition are started simultaneously. Add this command after the set of run_commands.
stop	None	Stops data acquisition.
close_session	None	Closes the currently open SignalTap II file. You cannot run the analyzer after the SignalTap II file is closed.

For more information about SignalTap II Tcl commands, refer to the Quartus II Help.

**Example 13–4** is an excerpt from a script that is used to continuously capture data. Once the trigger condition is met, the data is captured and stored in the data log.

**Example 13–4.**

```
#opens signaltap session
open_session -name stp1.stp
#start acquisition of instance auto_signaltap_0 and
#auto_signaltap_1 at the same time
#calling run_multiple_end will start all instances
#run after run_multiple_start call
run_multiple_start
run -instance auto_signaltap_0 -signal_set signal_set_1 -trigger /
trigger_1 -data_log log_1 -timeout 5
run -instance auto_signaltap_1 -signal_set signal_set_1 -trigger /
trigger_1 -data_log log_1 -timeout 5
run_multiple_end
#close signaltap session
close_session
```

Once the script is completed, you should open the SignalTap II file that you used to capture data to examine the contents of the Data log.

## Design Example: Using SignalTap II Logic Analyzers in SOPC Builder Systems

Altera Application Note, *AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems* describes how to use the SignalTap II Logic Analyzer to monitor signals located inside a system module generated by SOPC Builder. The system in this example contains many components, including a Nios processor, a direct memory access (DMA) controller, on-chip memory, and an interface to external SDRAM memory. In this example, the Nios processor executes a simple C program from on-chip memory and waits for a button push. After a button is pushed, the processor initiates a DMA transfer, which you analyze using the SignalTap II Logic Analyzer.

For more information about this example and using the SignalTap II Logic Analyzer with SOPC builder systems refer to *AN 323: Using SignalTap II Embedded Logic Analyzers in SOPC Builder Systems* and *AN 446: Debugging NIOS II Systems with the SignalTap II Logic Analyzer*.

## Custom Triggering Flow Application Examples

The custom triggering flow in the SignalTap II Logic Analyzer is most useful for organizing a number of triggering conditions and for precise control over the acquisition buffer. This section provides two application examples for defining a custom triggering flow within the SignalTap II Logic Analyzer. Both examples can be easily copied and pasted directly into the state machine description box by using the state display mode **All states in one window**.

For additional triggering flow design examples, refer to the [Quartus II On-Chip Debugging Support Resources](#) page for on-chip debugging.

### Design Example 1: Specifying a Custom Trigger Position

Actions to the acquisition buffer can accept an optional post-count argument. This post-count argument enables you to define a custom triggering position for each segment in the acquisition buffer. [Example 13-5](#) shows an example that applies a trigger position to all segments in the acquisition buffer. The example describes a triggering flow for an acquisition buffer split into four segments. If each acquisition segment is 64 samples in depth, the trigger position for each buffer will be at sample #34. The acquisition stops after all four segments are filled once.

**Example 13-5.**

```

if (c1 == 3 && condition1)
    trigger 30;
else if ( condition1 )
begin
    segment_trigger 30;
    increment c1;
end
end
    
```

Each segment acts as a circular buffer, that continuously updates the memory contents with the signal values. The last acquisition before stopping the buffer is the displayed on the data tab as the last sample number in the affected segment. The trigger position in the affected segment is then defined by *N - post count fill*, where *N* is the number of samples per segment. [Figure 13-32](#) illustrates the triggering position.

**Figure 13-32. Specifying a Custom Trigger Position**

**Design Example 2: Trigger When triggercond1 Occurs Ten Times between triggercond2 and triggercond3**

The custom trigger flow description is often useful to count a sequence of events before triggering the acquisition buffer. [Example 13-6](#) on [page 13-79](#) shows such a sample flow. This example uses three basic triggering conditions configured in the SignalTap II setup tab.

This example triggers the acquisition buffer when `condition1` occurs after `condition3` and occurs ten times prior to `condition3`. If `condition3` occurs prior to ten repetitions of `condition1`, the state machine transitions to a permanent wait state.

---

**Example 13–6.**

```
state ST1:
```

```
if ( condition2 )
begin
    reset c1;
    goto ST2;
end
```

```
State ST2 :
```

```
if ( condition1 )
    increment c1;
```

```
else if (condition3 && c1 < 10)
    goto ST3;
```

```
else if ( condition3 && c1 >= 10)
    trigger;
```

```
ST3:
```

```
goto ST3;
```

---

## Conclusion

As the FPGA industry continues to make technological advancements, outdated methodologies need to be replaced with new technologies that maximize productivity. The SignalTap II Logic Analyzer gives you the same benefits as a traditional logic analyzer, without the many shortcomings of a piece of dedicated test equipment. This version of the SignalTap II Logic Analyzer provides many new and innovative features that allow you to capture and analyze internal signals in your FPGA, allowing you to find the source of a design flaw in the shortest amount of time.

# Document Revision History

Table 13–15 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v.7.2.0	Updated for the Quartus II software version 7.2: <ul style="list-style-type: none"> <li>• Added new section: “Trigger Condition Flow Control” on page 13–34</li> <li>• Documented the new feature for State-machine-based triggering</li> <li>• Documented changes to “Using Incremental Compilation with the SignalTap II Logic Analyzer” on page 13–52</li> <li>• Added additional information about node tappability</li> <li>• Added section “Performance and Resource Considerations” on page 13–55, with information about performance and resource utilization considerations for the SignalTap II Logic Analyzer</li> </ul>	Updated for the Quartus II software version 7.2
May 2007 v7.1.0	Added “Referenced Documents” on page 13–71, minor updates to address ADoQS issues.	—
March 2007 v7.0.0	Added Cyclone III device support listed on page 13–4.	—
November 2006 v6.1.0	Updated for the Quartus II software version 6.1: <ul style="list-style-type: none"> <li>• Updated Figure 13-4, 13-11, 13-16, 13-17, 13-18. Added new Figure 13-23.</li> <li>• Miscellaneous changes throughout.</li> <li>• Removed information about incremental routing (feature removed).</li> <li>• Added more detail about the use of incremental compilation.</li> <li>• Added more detail about the use of the Nios II plug-in.</li> <li>• Added more information about SignalTap II file/SOF compatibility.</li> <li>• Updated method for triggering one logic analyzer with another using trigger in/out.</li> </ul>	Updated for the Quartus II software version 6.1.
May 2006 v6.0.0	Updated for the Quartus II software version 6.0.	—
October 2005 v5.1.0	Updated for the Quartus II software version 5.1.	—
May 2005 v5.0.0	<ul style="list-style-type: none"> <li>• Updated information.</li> <li>• Updated figures.</li> <li>• New functionality for Quartus II software 5.0.</li> </ul>	—
December 2004 v1.0	Initial release.	—

## Introduction

The phenomenal growth in design size and complexity continues to make the process of design verification a critical bottleneck for today's FPGA systems. Limited access to internal signals, advanced FPGA packages, and printed circuit board (PCB) electrical noise are all contributing factors in making design debugging and verification the most difficult process of the design cycle. You can easily spend more than 50% of your design cycle time debugging and verifying your design. To help you with the process of design debugging and verification, Altera® provides a solution that allows you to examine the behavior of internal signals using an external logic analyzer and using a minimal number of FPGA I/O pins, while your design is running at full speed on your FPGA.

This chapter's use of 'logic analyzer' includes both logic analyzers and oscilloscopes equipped with digital channels, commonly referred to as mixed signal analyzers or MSOs.

The Logic Analyzer Interface is an application within the Quartus II software used to connect a large set of internal device signals to a small number of output pins. You can connect these output pins to an external logic analyzer for debugging purposes. The Logic Analyzer Interface enables you to connect to and transmit internal signals buried within your FPGA to an external logic analyzer for analysis. The Quartus II Logic Analyzer Interface allows you to debug a large set of internal signals using a small number of output pins. In the Quartus II Logic Analyzer Interface, the internal signals are grouped together, distributed to a user-configurable multiplexer, and then output to available I/O pins on your FPGA. Instead of having a one-to-one relationship between internal signals to output pins, the Quartus II Logic Analyzer Interface enables you map many internal signals to a smaller number of output pins. The exact number of internal signals that you can map to an output pin varies based on the multiplexer settings in the Quartus II Logic Analyzer Interface.

Optionally, you can use the Logic Analyzer Interface with the Quartus II Incremental Compilation.

## Choosing a Logic Analyzer

During the debugging phase of your project, you have the choice of using:

- SignalTap® II, the embedded logic analyzer.
- An external logic analyzer, which connects to internal signals in your FPGA, by using the Quartus II Logic Analyzer Interface.

Table 14–1 describes the advantages to both debugging technologies.

<b>Feature</b>	<b>Logic Analyzer Interface</b>	<b>SignalTap II Embedded Logic Analyzer</b>
<b>Sample Depth</b> —You will have access to a wider sample depth with an external logic analyzer. In SignalTap II, the maximum sample depth is set to 128 Kb, which is a device constraint. However, with an external logic analyzer, there are no device constraints, providing you a wider sample depth.	✓	—
<b>Debugging Timing Issues</b> —Using an external logic analyzer provides you with access to a “timing” mode, which enables you to debug combined streams of data.	✓	—
<b>Performance</b> —You frequently have limited routing resources available to place-and-route when you use SignalTap II with your design. An external logic analyzer adds minimal logic, which removes resource limits on place-and-route.	✓	—
<b>Triggering Capability</b> —Although advanced triggering is available in SignalTap II, many additional triggering options are available on an external logic analyzer.	✓	—
<b>Use of Output Pins</b> —Using the SignalTap II Logic Analyzer, no additional output pins are required. Using an external logic analyzer requires the use of additional output pins.	—	✓
<b>Acquisition Speed</b> —With the SignalTap II Logic Analyzer, you can acquire data at speeds of over 200 MHz. You can achieve the same acquisition speeds with an external logic analyzer, however you have to consider signal integrity issues.	—	✓

## Required Components

You must have the following components to perform analysis using the Quartus II Logic Analyzer Interface:

- The Quartus II software starting with version 5.1 and later
- The device under test
- An external logic analyzer
- An Altera communications cable
- A cable to connect the FPGA to the external logic analyzer

Figure 14–1 shows the Logic Analyzer Interface and the hardware setup.

**Figure 14–1. Logic Analyzer Interface and Hardware Setup**

**Notes to Figure 14–1:**

- (1) Configuration and control of the LAI using computer loaded with Quartus II via the JTAG port.
- (2) Configuration and control of the LAI using a third-party vendor logic analyzer via the JTAG port. Support varies by vendor.

## FPGA Device Support

You can use the Quartus II Logic Analyzer Interface with the following FPGA device families:

- Arria™ GX
- Stratix® III
- Stratix II
- Stratix II GX
- Stratix
- Stratix GX

- Cyclone® III
- Cyclone II
- Cyclone
- MAX® II
- APEX™ 20K
- APEX II

## Debugging Your Design Using the Logic Analyzer Interface

Figure 14–2 shows the steps you must follow to debug your design with the Quartus II Logic Analyzer Interface.

**Figure 14–2. Logic Analyzer Interface Process Flow**

### Creating a Logic Analyzer Interface File

The Logic Analyzer Interface File (.lai), defines the interface that builds a connection between internal FPGA signals and your external logic analyzer. An example of a Logic Analyzer Interface File is shown in Figure 14–3.

Figure 14–3. Example of a Logic Analyzer Interface Editor

To define the Quartus II Logic Analyzer Interface, you can create a new Logic Analyzer Interface File or use an existing Logic Analyzer Interface File.

#### *Creating a New Logic Analyzer Interface File*

To create a new Logic Analyzer Interface File, perform the following steps:

1. In the Quartus II software, on the File menu, click **New**. The **New** dialog box opens.
2. Click the **Other Files** tab and select **Logic Analyzer Interface File** (Figure 14–4).

**Figure 14–4. Creating a New Logic Analyzer File**

3. Click **OK**. The Logic Analyzer Interface editor opens. The file name is assigned by the Quartus II software (refer to [Figure 14–3 on page 14–5](#)). When you save the file, you will be prompted for a file name. Refer to [“Saving the External Analyzer Interface File” on page 14–7](#).

#### *Opening an Existing External Analyzer Interface File*

To open an existing Logic Analyzer Interface File, on the Tools menu, click **Logic Analyzer Interface Editor**. If no Logic Analyzer Interface File is enabled for the current project, the editor automatically creates a new Logic Analyzer Interface File. If a Logic Analyzer Interface File is currently enabled for the project, that file opens when you select the **Logic Analyzer Interface Editor**.

Another way to open an existing Logic Analyzer Interface File is on the File Menu, click **Open**, and select the Logic Analyzer Interface File you want to open.

### *Saving the External Analyzer Interface File*

To save your Logic Analyzer Interface File, perform the following steps:

1. In the Quartus II software, on the File menu, click **Save As**, The **Save As** dialog box opens (Figure 14–5).
2. In the **File name** box, enter the desired file name. Click **Save** (Figure 14–5).

---

**Figure 14–5. Saving the Logic Analyzer Interface File**

---

### **Configuring the Logic Analyzer Interface File Core Parameters**

After you have created your Logic Analyzer Interface File, you must configure the Logic Analyzer Interface File core parameters.

To configure the Logic Analyzer Interface File core parameters, select **Core Parameters** from the Setup View list. Refer to Figure 14–6.

**Figure 14–6. Logic Analyzer Interface File Core Parameters**

Table 14–2 lists the Logic Analyzer Interface File core parameters.

<b>Table 14–2. Logic Analyzer Interface File Core Parameters (Part 1 of 2)</b>	
<b>Parameter</b>	<b>Description</b>
Pin Count	<p>The Pin Count parameter signifies the number of pins you want dedicated to your Logic Analyzer Interface. The pins need to be connected to a debug header on your board. Within the FPGA, each pin is mapped to a user-configurable number of internal signals.</p> <p>The Pin Count parameter can range from 1 to 256 pins.</p>
Bank Count	<p>The Bank Count parameter signifies the number of internal signals that you want to map to each pin. For example, a Bank Count of 8 implies that you will connect eight internal signals to each pin.</p> <p>The Bank Count parameter can range from 1 to 256 banks.</p>
Output/ Capture Mode	<p>The Output/Capture Mode parameter signifies the type of acquisition you perform. There are two options that you can select:</p> <p>Combinational/Timing—This acquisition uses your external logic analyzer’s internal clock to determine when to sample data. Because Combinational/Timing acquisition samples data asynchronously to your FPGA, you need to properly determine the sample frequency you should use to debug and verify your system. This mode is effective if you want to measure timing information such as channel-to-channel skew. For more information on the sampling frequency, and what speeds it can run at refer to the data sheet for your external logic analyzer.</p> <p>Registered/State—This acquisition uses a signal from your system under test to determine when to sample. Because Registered/State acquisition samples data synchronously with your FPGA, it provides you with a functional view of your FPGA while it is running. This mode is effective when you want to verify the functionality of your design.</p>

**Table 14–2. Logic Analyzer Interface File Core Parameters (Part 2 of 2)**

Parameter	Description
Clock	The clock parameter is available only when Output/Capture Mode is set to Registered State. You must specify the sample clock in the Core Parameters view. The sample clock can be any signal in your design. However, for best results, Altera recommends that you use a clock with an operating frequency fast enough to sample the data you would like to acquire.
Power-Up State	The Power-Up State parameter specifies the power-up state of the pins you have designated for use with the Logic Analyzer Interface. You have the option of selecting tri-stated for all pins, or selecting a particular bank that you have enabled.

## Mapping the Logic Analyzer Interface File Pins to Available I/O Pins

To configure the Logic Analyzer Interface File I/O pins parameters, select Pins from the Setup View list (Figure 14–7).

**Figure 14–7. Logic Analyzer Interface File Pins Parameters**

Setup View: Pins				
Type	Index	Pin		I/O Standard
		Name	Location	
	0	altera_reserved_jai_0_0		
	1	altera_reserved_jai_0_1		
	2	altera_reserved_jai_0_2		
	3	altera_reserved_jai_0_3		
	4	altera_reserved_jai_0_4		
	5	altera_reserved_jai_0_5		
	6	altera_reserved_jai_0_6		
	7	altera_reserved_jai_0_7		

To assign pin locations for the Logic Analyzer Interface, double-click the **Location** column next to the reserved pins in the **Names** column. This opens the Pin Planner.

For information on how to use the Pin Planner, refer to the *Pin Planner* section in the *I/O Management* chapter in volume 2 of the *Quartus II Handbook*.

## Mapping Internal Signals to the Logic Analyzer Interface Banks

After you have specified the number of banks to use in the Core Parameters settings page, you must assign internal signals for each bank in the Logic Analyzer Interface. Click the **Setup View** arrow and select **Bank *n*** or **ALL Banks** (Figure 14–8).

**Figure 14–8. Logic Analyzer Interface Bank Parameters**

Setup View: Bank 0				
Pin Index	Node			
	Type	Alias	Name	
0		State Clock	<input type="text"/>	
1				
2				
3				
4				
5				
6				
7				

To view all of your bank connections, click **Setup View** and select **All Banks** (Figure 14–9).

**Figure 14–9. Logic Analyzer Interface All Bank Parameters**

Setup View: All Banks				
Bank Name	Pin Index	Node		
		Type	Alias	Name
Bank 0	0			<input type="text" value="d[7]"/>
	1			d[6]
	2			d[5]
	3			d[4]
	4			d[3]
	5			d[2]
	6			d[1]
Bank 1	7			d[0]
	0			
	1			
	2			
	3			
	4			
	5			
6				
7				

### Using the Node Finder

Before making bank assignments, on the View menu, point to Utility Windows, and click **Node Finder**. Find the signals that you want to acquire, then drag and drop the signals from the Node Finder dialog box

into the bank **Setup View**. When adding signals, use **SignalTap II: pre-synthesis** for non-incrementally routed instances and **SignalTap II: post-fitting** for incrementally routed instances.

As you continue to make assignments in the bank Setup View, the schematic of your Logic Analyzer Interface in the Logical View of your Logic Analyzer Interface File begins to reflect your assignments (Figure 14–10).

**Figure 14–10. A Logical View of the Logic Analyzer Interface Schematic**

Continue making assignments for each bank in the **Setup View** until you have added all of the internal signals for which you wish to acquire data.

You can right-click to switch between the Logic Analyzer Interface schematic and the Logic Analyzer Interface Setup view.

### Enabling the Logic Analyzer Interface Before Compiling Your Quartus II Project

Compile your project after you have completed the following steps:

- Configure your Logic Analyzer Interface parameters
- Map the Logic Analyzer Interface pins to available I/O pins
- Map the internal signals to the Logic Analyzer Interface banks

## Compiling Your Quartus II Project

Before compilation, you must enable the Logic Analyzer Interface.

1. On the Assignments menu, click **Settings**. The **Settings** dialog box opens. Under Category, click **Logic Analyzer Interface**. The **Logic Analyzer Interface** displays. Turn on **Enable Logic Analyzer Interface**.
2. Click **Logic Analyzer Interface file name** and specify the full path name to your Logic Analyzer Interface File (Figure 14–11).

**Figure 14–11. Settings Dialog Box—Logic Analyzer Interface Settings**

After you have specified the name of your Logic Analyzer Interface File, you must compile your project. To compile your project, on the Processing menu, click **Start Compilation**.

To ensure the Logic Analyzer Interface is properly compiled with your project, expand the entity hierarchy in the Project Navigator. (To display the Project Navigator, on the View menu, point to **Utility Windows**, and click **Project Navigator**.) If the Logic Analyzer Interface compiled with your design, the `sld_hub` and `sld_multitap` entities are shown in the project navigator.

**Figure 14–12. Project Navigator**

Entity	Logic Cells	LC Registers
Stratix: EP1S10B672C7		
test	136 (1)	81
sld_multitap:auto_lai_0	35 (11)	15
sld_hub:sld_hub_inst	100 (25)	65

## Programming Your FPGA Using the Logic Analyzer Interface

After compilation completes, you must configure your FPGA before using the Logic Analyzer Interface. To configure a device for use with the Logic Analyzer Interface, follow these steps:

1. Open the Logic Analyzer Interface File Editor (Figure 14–13).
2. Under **JTAG Chain Configuration**, click **Hardware** and select your hardware communications device. You may have to click **Settings** to configure your hardware.
3. Click **Device** and select the FPGA device to which you want to download the design (it may be automatically detected). You may have to click **Scan Chain** to configure your device.
4. Click **File** and select the SRAM Object File (`.sof`) that includes the Logic Analyzer Interface File (it may be automatically detected).
5. If desired, turn on **Incremental Compilation**.
6. Save the Logic Analyzer Interface File.
7. Click the **Program Device** icon to program the device.

Figure 14–13. The JTAG Section of the Logic Analyzer Interface File

## Using the Logic Analyzer Interface with Multiple Devices

You can use the Logic Analyzer Interface with multiple devices in your JTAG chain. Your JTAG chain can also consist of devices that do not support the Logic Analyzer Interface or non-Altera, JTAG-compliant devices. To use the Logic Analyzer Interface in more than one FPGA, create a Logic Analyzer Interface and configure a Logic Analyzer Interface File for each FPGA that you want to analyze. To perform multi-FPGA analysis, perform the following steps:

1. Open the Quartus II software.
2. Create, configure, and compile a Logic Analyzer Interface File for each design.
3. Open one Logic Analyzer Interface File at a time.

You do not have to open a Quartus II project to open a Logic Analyzer Interface File.

4. Follow Steps 2 through 6 under “[Programming Your FPGA Using the Logic Analyzer Interface](#)” on page 14–13.
5. Click the **Program Device** icon to program the device.
6. Control each Logic Analyzer Interface File independently.

## Configuring Banks in the Logic Analyzer Interface File

When you have programmed your FPGA, you can control which bank is mapped to the reserved Logic Analyzer Interface File output pins. To control which bank is mapped, right-click on the bank in the schematic in the logical view and click **Connect Bank**.

Figure 14–14. Configuring Banks

## Acquiring Data on Your Logic Analyzer

To acquire data on your logic analyzer, you must establish a connection between your device and the external logic analyzer.

For more information on this process, and for guidelines on how to establish connections between debugging headers and logic analyzers, refer to the documentation for your logic analyzer.

## Advanced Features

This section describes the following advanced features:

- Using the Logic Analyzer Interface with Incremental Compilation
- Creating Multiple Logic Analyzer Interface Instances in One FPGA

### Using the Logic Analyzer Interface with Incremental Compilation

Using the Logic Analyzer Interface with Incremental Compilation enables you to preserve the synthesis and fitting of your original design and add the Logic Analyzer Interface to your design without recompiling your original source code.

To use the Logic Analyzer Interface with Incremental Compilation, perform the following steps:

1. Start the Quartus II software.

2. Enable Design Partitions. To enable Partitions, perform the following steps:
  - a. On the Assignments menu, click, **Design Partitions**.
  - b. In the **Incremental Compilation** list, select **Full Incremental Compilation**.
  - c. Create Design Partitions for the entities in your design, and set the Netlist Type to **Post-fit**.
  - d. On the Processing menu, click **Start Compilation**.
3. Enable Logic Analyzer Interface Incremental Compilation by performing these steps:
  - a. In your Logic Analyzer Interface File, under **Instance Manager**, click **Incremental Compilation**.

When you enable Incremental Compilation, all existing presynthesis signals will be converted into post-fitting signals. Only post-fitting signals can be used with the Logic Analyzer Interface with Incremental Compilation.

- b. Add Post-Fitting nodes to your Logic Analyzer Interface File.
- c. On the Processing menu, click **Start Compilation**.

## Creating Multiple Logic Analyzer Interface Instances in One FPGA

The Logic Analyzer Interface includes support for multiple interfaces in one FPGA. This feature is particularly useful when you want to build Logic Analyzer Interface configurations that contain different settings. For example, you can build one Logic Analyzer Interface instance to perform Registered/State analysis and build another instance that performs Combinational/Timing analysis on the same set of signals.

Another example would be if you want to perform Registered/State analysis on portions of your design that are in different clock domains.

To create multiple Logic Analyzer Interfaces, on the Edit menu, click **Create Instance**. Alternatively, you can right-click in the Instance Manager window, and click **Create Instance**.

**Figure 14–15. Creating Multiple Logic Analyzer Interface Instances in One FPGA**

Instance	Status	Incremental Compilation	LEs: 170
<input type="checkbox"/> auto_lai_0	Not connected	<input type="checkbox"/>	85 cells
<input checked="" type="checkbox"/> auto_lai_1	Not connected	<input type="checkbox"/>	85 cells

Rename Instance F2
Instance Status Help

## Conclusion

As the FPGA industry continues to make technological advancements, outdated debugging methodologies must be replaced with new technologies that maximize productivity. The Logic Analyzer Interface feature enables you to connect many internal signals within your FPGA to an external logic analyzer with the use of a small number of I/O pins. This new technology in the Quartus II software enables you to use feature-rich external logic analyzers to debug your FPGA design, ultimately enabling you to deliver your product in the shortest amount of time.

## Document Revision History

Table 14–3 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	No changes to content.	—
May 2007 v7.1.0	Minor updates to address ADoQS issues.	—
March 2007 v7.0.0	Added Cyclone III device support listed on <a href="#">page 14–3</a> .	—
November 2006 v6.1.0	Added new revision history table format to this document.	—
May 2006 v6.0.0	Chapter title changed. Minor updates for the Quartus II software version 6.0.0.	—
October 2005 v5.1.0	Initial release.	—

## Introduction

FPGA designs are growing larger in density and are becoming more complex. Designers and verification engineers require more access to the design that is programmed in the device to quickly identify, test, and resolve issues. The in-system updating of memory and constants capability of the Quartus® II software provides read and write access to in-system FPGA memories and constants through the Joint Test Action Group (JTAG) interface, making it easier to test changes to memory contents in the FPGA while the FPGA is functioning in the end system.

This chapter explains how to use the Quartus II In-System Memory Content Editor as part of your FPGA design and verification flow.

This chapter contains the following sections:

- [“Device Megafunction Support” on page 15–2](#)
- [“Using In-System Updating of Memory Constants with Your Design” on page 15–3](#)
- [“Creating In-System Modifiable Memories Constants” on page 15–3](#)
- [“Running the In-System Memory Content Editor” on page 15–4](#)

## Overview

The ability to read and update memories and constants in a programmed device provides more insight into and control over your design. The Quartus II In-System Memory Content Editor gives you access to device memories and constants. When used in conjunction with the SignalTap® II embedded logic analyzer, this feature provides you the visibility required to debug your design in the hardware lab.

For more information on the SignalTap II embedded logic analyzer, refer to the *Design Debugging Using the SignalTap II Embedded Logic Analyzer* chapter in volume 3 of the *Quartus II Handbook*.

The ability to read data from memories and constants allows you to quickly identify the source of problems. In addition, the write capabilities allow you to bypass functional issues by writing expected data. For example, if a parity bit in your memory is incorrect, you can use the In-System Content Editor to write the correct parity bit values into your RAM, allowing your system to continue functioning. You can also intentionally write incorrect parity bit values into your RAM to check your design's error handling functionality.

## Device Megafunction Support

The following tables list the devices and types of memories and constants that are currently supported by the Quartus II software. Table 15–1 lists the types of memory supported by the MegaWizard® Plug-In Manager and the In-System Memory Content Editor.

Installed Plug-Ins Category	Megafunction Name
Gates	LPM_CONSTANT
Memory Compiler	RAM: 1 - PORT, ROM: 1 - PORT
Storage	ALTSYNCRAM, LPM_RAM_DQ, LPM_ROM

Table 15–2 lists support for in-system updating of memory and constants for the Stratix® series, Arria™ GX, Cyclone® series, APEX™ II, APEX 20K, and Mercury™ device families.

MegaFunction	Arria GX / Stratix Series			Cyclone Series	APEX II	APEX 20K	Mercury
	M512 Blocks	M4K Blocks	MegaRAM Blocks				
LPM_CONSTANT	Read/ Write	Read/ Write	Read/ Write	Read/ Write	Read/ Write	Read/ Write	Read/ Write
LPM_ROM	Write	Read/ Write	N/A	Read/ Write	Read/ Write	Write	Read/ Write
LPM_RAM_DQ	N/A	Read/ Write	Read/ Write	Read/ Write	Read/ Write	N/A (1)	Read/ Write
ALTSYNCRAM (ROM)	Write	Read/ Write	N/A	Read/ Write	N/A	N/A	N/A
ALTSYNCRAM (Single-Port RAM Mode)	N/A	Read/ Write	Read/ Write	Read/ Write	N/A	N/A	N/A

**Note to Table 15–2:**

- (1) Only write-only mode is applicable for this single-port RAM. In read-only mode, use LPM\_ROM instead of LPM\_RAM\_DQ.

## Using In-System Updating of Memory Constants with Your Design

Using the In-System Updating of Memory and Constants feature requires the following steps:

1. Identify the memories and constants that you want to access.
2. Edit the memories and constants to be run-time modifiable.
3. Perform a full compilation.
4. Program your device.
5. Launch the In-System Memory Content Editor.

## Creating In-System Modifiable Memories Constants

When you specify that a memory or constant is run-time modifiable, the Quartus II software changes the default implementation. A single-port RAM is converted to dual-port RAM, and a constant is implemented in registers instead of look-up tables (LUTs). These changes enable run-time modification without changing the functionality of your design. For a list of run-time modifiable megafunctions, refer to [Table 15-1](#).

To enable your memory or constant to be modifiable, perform the following steps:

1. On the Tools menu, click **MegaWizard Plug-In Manager**.
2. If you are creating a new megafunction, select **Create a new custom megafunction variation**. If you have an existing megafunction, select **Edit an existing custom megafunction variation**.
3. Make the necessary changes to the megafunction based on the characteristics required by your design, turn on **Allow In-System Memory Content Editor to capture and update content independently of the system clock** and type a value in the **Instance ID** text box. These parameters can be found on the last page of the wizard for megafunctions that support in-system updating.

The Instance ID is a four-character string used to distinguish the megafunction from other in-system memories and constants.

4. Click **Finish**.
5. On the Processing menu, click **Start Compilation**.

If you instantiate a memory or constant megafunction directly using ports and parameters in VHDL or Verilog HDL, add or modify the `lpm_hint` parameter as shown below.

In VHDL code, add the following:

```
lpm_hint => "ENABLE_RUNTIME_MOD = YES,
           INSTANCE_NAME = <instantiation name>";
```

In Verilog HDL code, add the following:

```
defparam <megafunction instance name>.lpm_hint =
    "ENABLE_RUNTIME_MOD = YES,
    INSTANCE_NAME = <instantiation name>";
```

## Running the In-System Memory Content Editor

The In-System Memory Content Editor is separated into the Instance Manager, JTAG Chain Configuration, and the Hex Editor (Figure 15-1).

Figure 15-1. In-System Memory Content Editor

The Instance Manager displays all available run-time modifiable memories and constants in your FPGA device. The JTAG Chain Configuration section allows you to program your FPGA and select the Altera® device in the chain to update.

Using the In-System Memory Content Editor does not require that you open a project. The In-System Memory Content Editor retrieves all instances of run-time configurable memories and constants by scanning the JTAG chain and sending a query to the specific device selected in the JTAG Chain Configuration section.

Each In-System Memory Content Editor can access the in-system memories and constants in a single device. If you have more than one device containing in-system configurable memories or constants in a JTAG chain, you can launch multiple In-System Memory Content Editors within the Quartus II software to access the memories and constants in each of the devices.

## Instance Manager

Scan the JTAG chain to update the Instance Manager with a list of all run-time modifiable memories and constants in the design. The Instance Manager displays the Index, Instance, Status, Width, Depth, Type, and Mode of each element in the list.

You can read and write to in-system memory using the Instance Manager as shown in [Figure 15-2](#).

**Figure 15-2. Instance Manager Controls**

The following buttons are provided in the Instance Manager:

- **Read data from In-System Memory**—reads the data from the device independently of the system clock and displays it in the Hex Editor
- **Continuously Read Data from In-System Memory**—Continuously reads the data asynchronously from the device and displays it in the Hex Editor
- **Stop In-System Memory Analysis**—Stops the current read or write operation

- **Write Data to In-System Memory**—Asynchronously writes data present in the Hex Editor to the device

In addition to the buttons available in the Instance Manager, you can also read and write data by selecting the command from the Processing menu, or the right button pop-up menu in the Instance Manager or Hex Editor.

The status of each instance is also displayed beside each entry in the Instance Manager. The status indicates if the instance is **Not running**, **Offloading data** or **Updating Data**. The health monitor provides useful information about the status of the editor.

The Quartus II software assigns a different index number to each in-system memory and constant to distinguish between multiple instances of the same memory or constant function. View the **In-System Memory Content Editor Setting** section of the compilation report to match an index with the corresponding instance ID (Figure 15–3).

**Figure 15–3. Compilation Report In-System Memory Content Editor Setting Section**

## Editing Data Displayed in the Hex Editor

You can edit the data read from your in-system memories and constants displayed in the Hex Editor by typing values directly into the editor or by importing memory files.

To modify the data displayed in the Hex Editor, click a location in the editor and type or paste in the new data. The new data appears as blue indicating modified data that has not been written into the FPGA. On the Edit menu, choose Value, and click **Fill with 0's**, **Fill with 1's**, **Fill with Random Values**, or **Custom Fills** to update a block of data by selecting a block of data.

## Importing Exporting Memory Files

Importing and exporting memory files lets you quickly update in-system memories with new memory images and record data for future use and analysis.

On the Edit menu, click **Import Data from File** to import a memory file, select an in-system memory or constant from the instance manager. You can only import a memory file that is in either a Hexadecimal (Intel-Format) file (**.hex**) or memory initialization file (**.mif**) format.

On the Edit menu, click **Export Data to File** to export data displayed in the Hex Editor to a memory file, to select an in-system memory or constant from the instance manager. You can export data to a **.hex**, **.mif**, Verilog Value Change Dump file (**.vcd**), or RAM Initialization file (**.rif**) format.

## Viewing Memories Constants in the Hex Editor

For each instance of an in-system memory or constant, the Hex Editor displays data in hexadecimal representation and ASCII characters (if the word size is a multiple of 8 bits). The arrangement of the hexadecimal numbers depends on the dimensions of the memory. For example, if the word width is 16 bits, the Hex Editor displays data in columns of words that contain columns of bytes (Figure 15-4).

**Figure 15–4. Editing 16-Bit Memory Words Using the Hex Editor**

Unprintable ASCII characters are represented by a period (.). The color of the data changes as you perform reads and writes. Data displayed in black indicates the data in the Hex Editor was the same as the data read from the device. If the data in the Hex Editor changes color to red, the data previously shown in the Hex Editor was different from the data read from the device.

As you analyze the data, you can use the cursor and the status bar to quickly identify the exact location in memory. The status bar is located at the bottom of the In-System Memory Content Editor and displays the selected instance name, word position, and bit offset (Figure 15–5).

**Figure 15–5. Status Bar in the In-System Memory Content Editor**

The bit offset is the bit position of the cursor within the word. In the following example, a word is set to be 8-bits wide.

With the cursor in the position shown in Figure 15–6, the word location is 0x0000 and the bit position is 0x0007.

**Figure 15–6. Hex Editor Cursor Positioned at Bit 0x0007**

With the cursor in the position shown in [Figure 15–7](#), the word location remains 0x0000 but the bit position is 0x0003.

**Figure 15–7. Hex Editor Cursor Positioned at Bit 0x0003**

## Scripting Support

The In-System Memory Content Editor supports reading and writing of memory contents via a Tcl script or Tcl commands entered in a command prompt. For detailed information about scripting command options, refer to the Quartus II command-line and Tcl API Help browser.

To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp r
```

The *Quartus II Scripting Reference Manual* includes the same information in PDF form.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

The commonly used commands for the In-System Memory Content Editor are as follows:

- Reading from memory:
 

```
read_content_from_memory
[-content_in_hex]
-instance_index <instance index>
-start_address <starting address>
-word_count <word count>
```

- Writing to memory:  
`write_content_to_memory`
- Save memory contents to file:  
`save_content_from_memory_to_file`
- Update memory contents from File:  
`update_content_to_memory_from_file`

For descriptions about the command options and scripting examples, refer to the Tcl API Help Browser and the *Quartus II Scripting Reference Manual*.

## Programming the Device Using the In-System Memory Content Editor

If you make changes to your design, you can program the device from within the In-System Memory Content Editor. To program the device, follow these steps:

1. On the Tools menu, click **In-System Memory Content Editor**.
2. In the **JTAG Chain Configuration** panel of the In-System Memory Content Editor, select the SRAM object file (`.sof`) that includes the modifiable memories and constants.
3. Click **Scan Chain**.
4. In the **Device** list, select the device you want to program.
5. Click **Program Device**.

### Example: Using the In-System Memory Content Editor with the SignalTap II Embedded Logic Analyzer

The following scenario describes how you can use the In-System Updating of Memory and Constants feature with the SignalTap II embedded logic analyzer to efficiently debug your design in-system. Although both the In-System Content Editor and the SignalTap II embedded logic analyzer use the JTAG communication interface, you are able to use them simultaneously.

After completing your FPGA design, you find that the characteristics of your FIR filter design are not as expected.

1. To locate the source of the problem, change all your FIR filter coefficients to be in-system modifiable and instantiate the SignalTap II embedded logic analyzer.
2. Using the SignalTap II embedded logic analyzer to tap and trigger on internal design nodes, you find the FIR filter to be functioning outside of the expected cut-off frequency.
3. Using the **In-System Memory Content Editor**, you check the correctness of the FIR filter coefficients. Upon reading each coefficient, you discover that one of the coefficients is incorrect.
4. Since your coefficients are in-system modifiable, you update the coefficients with the correct data using the **In-System Memory Content Editor**.

In this scenario, you are able to quickly locate the source of the problem using both the In-System Memory Content Editor and the SignalTap II embedded logic analyzer. You are also able to verify the functionality of your device by changing the coefficient values before modifying the design source files.

An extension to this example would be to modify the coefficients with the In-System Memory Content Editor to vary the characteristics of the FIR filter (for example, filter attenuation, transition bandwidth, cut-off frequency, and windowing function).

## Conclusion

The In-System Updating of Memory and Constants feature provides access into a device for efficient debug in a hardware lab. You can use In-System Memory Updating of Memory and Constants with the SignalTap II embedded logic analyzer to maximize the visibility into an Altera FPGA. By increasing visibility and access to internal logic of the device, you are able to more quickly identify and resolve problems with your design or its implementation.

## Introduction

Traditional debugging techniques often involve using an external pattern generator to exercise the logic and a logic analyzer to study the output waveforms during run-time. The SignalTap® II Logic Analyzer and SignalProbe allow you to read or “tap” internal logic signals during run-time as a way to debug your logic on-chip. While this is useful, the debugging cycle efficiency may be enhanced with the ability to drive any internal signal manually within your design. By doing this you can perform the following activities:

- Force the occurrence of trigger conditions setup in the SignalTap II Logic Analyzer
- Create simple test vectors to exercise your design without using external test equipment
- Dynamically control run-time control signals with the JTAG chain

With the introduction of the In-System Sources and Probes feature in the Quartus® II software beginning with version 7.1, Altera extends the portfolio of verification tools. The In-System Sources and Probes feature allows you to easily control any internal signal, providing you with a completely dynamic debugging environment. Coupled with either the SignalTap II Logic Analyzer or SignalProbe, the In-System Sources and Probes feature gives you a powerful debugging environment in which to generate stimuli and solicit responses from your logic design.

This chapter addresses the following topics:

- [“Design Flow Using In-System Sources and Probes” on page 16–4](#)
- [“Running the In-System Sources and Probes Editor” on page 16–9](#)
- [“TCL Support” on page 16–14](#)
- [“Design Example: Dynamic PLL Reconfiguration” on page 16–18](#)

## Overview

The In-System Sources and Probes feature consists of the `altsource_probe` megafunction and an interface to control the `altsource_probe` megafunction instances during run-time. Each `altsource_probe` megafunction instance provides you with source output ports and probe input ports, where source ports drive selected signals and probe ports sample selected signals. Upon compilation, the `altsource_probe` megafunction sets up a register chain to either drive or sample the selected nodes in your logic design. During runtime, the In-System Sources and Probes interface uses a JTAG connection to shift data to and

from the `altsource_probe` megafunction instances. Figure 16–1 shows a block diagram of the components that make up the In-System Sources and Probes feature.

**Figure 16–1. In-System Sources and Probes Block Diagram**

The `altsource_probe` megafunction hides the detailed transactions between the JTAG Hub and the registers instrumented in your design to give you a basic building block for stimulating and probing your design. Moreover, the In-System Sources and Probes feature provides single-cycle samples and single-cycle writes to the selected logic nodes. This provides an easy way to input simple virtual stimuli and an easy way to capture the current value on instrumented nodes. Because In-System Sources and Probes gives you access to logic nodes within your design, this feature can be used during the debugging process to toggle the inputs of low-level components. If used in conjunction with the SignalTap II Logic Analyzer, you can force trigger conditions to help isolate your problem and shorten your debugging process.

Additionally, the ease of use of the In-System Sources and Probes feature makes it ideal for implementing control signals as virtual stimuli. This feature can be especially helpful during for prototyping your design. Examples of such applications could include the ability to do the following:

- Create virtual push buttons
- Create a virtual front panel to interface with your design
- Mimic external sensor data
- Monitor and change run-time constants on the fly

In-System Sources and Probes supports Tcl commands to interface with all your `altsource_probe` instances to increase the level of automation.

The Virtual JTAG Megafunction and the In-System Memory Content Editor also give you the capability to drive virtual inputs into your design. The Virtual JTAG Megafunction gives you a greater level of control (compared to In-system Sources and Probes) in how your design communicates with the JTAG Hub at the cost of greater complexity. With the Virtual JTAG megafunction, you can design your own customized register scan chain to drive and control your logic through the JTAG port. The In-System Memory Content Editor is used specifically for reading and writing memory contents at runtime.

For more details about the Virtual JTAG Megafunction, refer to the *sld\_virtual\_jtag Megafunction User Guide*. For information about the In-System Memory Content Editor, refer to the *In-System Updating of Memory and Constants* chapter in volume 3 of the *Quartus II Handbook*.

## Hardware and Software Requirements

The following components are required to use In-System Sources and Probes:

- Quartus II design software  
or
- Quartus II Web Edition (with TalkBack feature enabled)
- Download Cable (USB-Blaster™ download cable or ByteBlaster™ cable)
- Altera® development kit or user design board with JTAG connection to device under test

The In-System Sources and Probes feature supports the following device families:

- Arria™ GX
- Stratix® III
- Stratix II
- Stratix II GX
- Stratix
- Stratix GX
- HardCopy® II
- HardCopy Stratix
- Cyclone® III
- Cyclone® II
- Cyclone
- MAX® II
- APEX™ II
- APEX 20KE
- APEX 20KC
- APEX 20K

## Design Flow Using In-System Sources and Probes

In-System Sources and Probes supports an RTL flow in which your design nodes are instrumented in your HDL code via instantiation of the `altsource_probe` megafunction. After your device is compiled with the design nodes that you want instrumented, you can control your `altsource_probe` instances via the Sources and Probes Editor GUI or via a Tcl interface. The complete design flow is shown in [Figure 16–2](#).

**Figure 16–2. FPGA Design Flow Using In-System Sources and Probes**

## Configuring the `altsource_probes` Megafunction

To add in-system sources and probes functionality to your design, you must first instantiate the `altsource_probe` megafunction variation file. The `altsource_probe` megafunction can be easily configured using the MegaWizard® Plug-In Manager. Each source or probe port can be up to 256 bits wide. You can have up to 128 instances of the `altsource_probe` megafunction in your design. The following steps will guide you through the steps necessary to configure the `altsource_probe` megafunction:

1. On the Tools menu, click **MegaWizard Plug-In Manager**.
2. Select **Create a new custom megafunction variation**.
3. Click **Next**.
4. On Page 2a, make the following selections:
  - a. In the Installed Plug-Ins list, expand the JTAG-accessible Extensions folder. In the JTAG-accessible Extensions list, select **In-System Sources and Probes**.
  - b. Make sure that the currently selected device family matches the device you are targeting.
  - c. Select an output file type and enter the desired name of the `altsource_probe` megafunction. You can choose AHDL (.tdf), VHDL (.vhd), or Verilog HDL (.v) as the output file type.
5. Click **Next**.
6. On Page 3, make the following selections:
  - a. Make sure that the currently selected device family matches the device that you are targeting.
  - b. Under **Do you want to specify an Instance Index?**, turn on **Yes**.
  - c. Specify the Instance ID of this instance.
  - d. Specify the width of the probe port. The width can be from 1 bit to 256 bits wide.
  - e. Specify the width of the source port. The width can be from 1 bit to 256 bits wide.

7. On Page 3, you can click **Advanced Options** and specify other parameters. The following options are included:
- **What is the initial value of the source port, in hexadecimal?**  
This option allows you to specify the initial value driven on the source port at run-time.
  - **Write data to the source port synchronously to the source clock.** This allows you to synchronize your source port write transactions with the clock domain of your choice.
  - **Create an enable signal for the registered source port.** When enabled, this creates a clock enable input for the synchronization registers. This option is enabled only when the **Write data to the source port synchronously to the source clock** option is enabled.

Table 16–1 summarizes the configurable fields for the `altsource_probe` megafunction.

<b>Options</b>	<b>Description</b>
Currently selected device family	Specifies the device family.
Do you want to specify an Instance Index?	Specifies the numeric index of the megafunction instance during run-time (from 0 to 127).
The 'Instance ID' of this Instance (optional):	Specifies the four character ID tag of the megafunction in the instance manager window of the Sources and Probes Editor.
How wide should the probe port be?	Specifies the number of signals to be read by In-System Sources and Probes.
How wide should the source port be?	Specifies the number of signals to be driven by In-System Sources and Probes.
What is the initial value of the source port (under <b>Advanced Options</b> )	Specifies the initial value driven on the source port at run time.
Write data to the source port synchronously to the source clock. Each bit in the source port will utilize two additional registers to achieve metastability (under <b>Advanced Options</b> )	Turning on this option allows you to synchronize your source port write transactions with the clock domain of your choice.
Create an enable signal for the registered source port (configured under <b>Advanced Options</b> )	Turning on this option creates a clock enable input for the synchronization registers.

## Instantiating the `altsource_probe` Megafunction

The MegaWizard Plug-in Manager produces the necessary variation file and the instantiation template based on your inputs to the MegaWizard. Use the template to instantiate the `altsource_probe` megafunction variation file in your design. The port information is shown in [Table 16–2](#).

Port Name	Required?	Direction	Comments
Probe []	No	Input	The outputs from the user's design.
Source_clk	No	Input	Source Data is written synchronously to this clock. This input is required if the Source Clock option is turned on in the Advanced Options box in the MegaWizard Plug-in Manager.
Source_ena	No	Input	Clock enable signal for <code>source_clk</code> . This input is required if specified in the Advanced Options box in the MegaWizard Plug-in Manager.
Source []	No	Output	Used to drive inputs to user design.

You can include up to 128 instances of the `altsource_probe` megafunction in your design, provided that there are available logic resources in your device. Each instance of the `altsource_probe` megafunction uses a pair of registers per signal for the width of the widest port it contains. Additionally, there will be some fixed overhead logic to accommodate communication between the `altsource_probe` instances and the JTAG controller. An additional pair of registers per source port is added for synchronization if it is specified.

## Compiling the Design

When you compile your design with the In-System Sources and Probes megafunction instantiated, an instance of the `altsource_probe` instance and `sld_hub` megafunctions are added to your compilation hierarchy automatically. These two instances allow communication between the JTAG controller and your instrumented logic.

To modify your In-System Sources and Probes connections, you can modify the number of connections to your design by editing the `altsource_probe` megafunction. You can open the MegaWizard Plug-In Manager for the design instance you want to modify by double-clicking the desired instance in the Project Navigator. You can then modify the connections in the HDL source file. You must recompile your design when you are finished editing it.

Because the design cycle is iterative in nature, you can use the Quartus II incremental compilation feature to reduce compilation time. Incremental compilation allows you to organize your design into logical partitions. During recompilation of a design, incremental compilation preserves the compilation results and performance of unchanged partitions and reduces design iteration time by compiling only modified design partitions.

For more information about Incremental Compilation, refer to the *Quartus II Incremental Compilation for Hierarchical & Team-Based Design* chapter in volume 1 of the *Quartus II Handbook*.

## Running the In-System Sources and Probes Editor

The In-System Sources and Probes Editor is a GUI that gives you control over all of the `altsource_probe` megafunction instances within your design. It displays all available run-time controllable instances of the `altsource_probe` megafunction in your design, provides a push-button interface to drive all of your source nodes, and a logging feature to store your probe and source data.

To run the In-System Sources and Probes Editor, from the **Tools** menu, click **In-System Sources and Probes Editor**.

Figure 16–3 shows the Editor window.

Figure 16–3. In-System Sources and Probes Editor

The In-System Sources and Probes Editor is made up of three panes:

- **JTAG Chain configuration**—Allows you to specify programming hardware, device, and file settings that the In-System Sources and Probes Editor uses to program and acquire data from a device.
- **Instance Manager**—Displays information about the instances generated when you compile a design, and allows you to control the data the In-System Sources and Probes Editor acquires.
- **Sources and Probes Editor**—Logs all the data read from the selected instance and allows you to modify source data to be written to your device.

Using the In-System Sources and Probes Editor does not require you to open a Quartus II project. The In-System Sources and Probes Editor retrieves all instances of the `altsource_probe` megafunction by scanning the JTAG chain and sending a query to the specific device selected in the JTAG Chain Configuration pane. Also, you can use a previously saved configuration to run the In-System Sources and Probes Editor.

Each In-System Sources and Probes Editor window can access the `altsource_probe` megafunction instances in a single device. If you have more than one device containing megafunction instances in a JTAG chain, you can launch multiple In-System Sources and Probes Editor windows to access the megafunction instances in each of the devices.

### Programming Your Device Using the JTAG Chain Configuration Window

After compilation is complete, you must configure your FPGA before using In-System Sources and Probes. To configure a device for use with the In-System Sources and Probes, perform the following steps:

1. Open the In-System Sources and Probes Editor.
2. Under JTAG Chain Configuration, point to **Hardware** and select the desired hardware communications device. You may be prompted to configure your hardware; in this case, click **Setup**.
3. From the **Device** list, select the FPGA device to which you want to download the design (it may be automatically detected). You may have to click **Scan Chain** to detect your target device.
4. In the JTAG Configuration window, click **Browse** and select the SRAM Object File (**.sof**) that includes the In-System Sources and Probes instance or instances. (Note that it may be automatically detected).
5. Click **Program Device** (next to **File:**) to program the target device.

## Instance Manager

The Instance Manager provides a list of all `altsource_probe` instances in the design and allows you to configure how data is acquired from or written to those instances.

The Instance Manager is shown in [Figure 16–4](#).

**Figure 16–4. Instance Manager**

The following buttons and sub-panes are provided in the Instance Manager:

- **Read Probe Data**—Samples the probe data in the selected instance and displays it in the Sources and Probes Editor Window
- **Continuously Read Probe Data**—Continuously samples the probe data of the selected instance and displays it in the Sources and Probes Editor Window; you can modify the sample rate via the Probe read interval setting
- **Stop Continuously Reading Probe Data**—Cancels continuous sampling of probe of selected instance
- **Write Source Data** sub-pane —Writes data to all source nodes of the selected instance
- **Probe Read Interval** sub-pane—Displays the sample interval of all the In-system Sources and Probe instances in your design; you can modify the sample interval by clicking **Manual**
- **Event Log** sub-pane—controls the event log in the Sources and Probes Editor Window
- **Write Source Data** sub-pane—Allows you to manually or continuously write data to the system

The status of each instance is also displayed beside each entry in the Instance Manager. The status indicates if the instance is **Not running**, **Offloading data**, **Updating data**, or if an “Unexpected JTAG communication error” occurs. The health monitor provides useful information about the status of the editor.

## Sources and Probes Editor Window

The Sources and Probes Editor window organizes and displays the data from all sources and probes in your design, organized according to the index number of the instance. The editor provides an easy way to manage your signals, allowing you to rename signals or to group them into buses. All data collected from source and probe nodes is recorded in the event log and displayed as a timing diagram.

### *Reading Probe Data*

You can read data by selecting the desired `altsource_probe` instance in the Instance Manager and clicking **Read Probe Data**. This produces a single sample of the probe data and updates the data column of the selected index in the Sources and Probes Editor window. You can save the data to an event log by turning on the **Save data to event log** option in the Instance Manager.

If you want to sample data from your probe instance continuously, in the Instance Manager, click the instance you want to read, and then click **Continuously read probe data**. While reading, the status of the active instance will show **Unloading**. You can read continuously from multiple instances.

You can access read data by using the right-click menus in the Instance Manager.

To adjust the probe read interval, in the Instance Manager, turn on the **Manual** option in the **Probe read interval** sub-pane, and specify the desired sample rate in the text field next to the **Manual** option. The maximum sample rate depends on your computer setup. The actual sample rate is shown in the **Current interval** box. The event log window buffer size can be adjusted in the **Maximum Size** box.

### *Writing Data*

To modify the source data to be written into the `altsource_probe` instance, click in the name field of the signal you want to change. For buses of signals, you can double-click on the data field and type in the value to be driven out to the `altsource_probe` instance. The In-System Sources and Probes Editor stores the modified source data values into a temporary

buffer. Modified values that have not been written out to the `altsource_probe` instances appear in red. To update the `altsource_probe` instance, highlight the instance in the Instance Manager and click **Write source data**. The **Write source data** function is also available via the shortcut menus in the Instance Manager.

You can choose to have the values stored in the In-System Sources and Probes Editor continuously update the `altsource_probe` instances. By doing so, any modifications you make to the source data buffer are written immediately to the `altsource_probe` instances. To continuously update the `altsource_probe` instances, change the **Write source data** field from **Manually** to **Continuously**.

### *Data Organization*

The main editor window allows you to group signals into buses, and allows you to modify the display options of the data buffer.

To create a group of signals, select the node names you want to group, right-click and select **Group**. You can modify the display format in the Bus Display Format and the Bus Bit order submenus.

The Sources and Probes Editor Window allows you to rename any signal. To rename a signal, double-click the name of the desired signal and type in the new name.

The event log contains a record of the most recent samples. The buffer size is adjustable, up to 128k samples. The time stamp for each sample is logged and is displayed above the event log of the instance being examined as you move your mouse pointer over the data samples.

You can save the changes that you have made and the recorded data into a Sources and Probes File (**.spf**). To save changes, on the File menu, click **Save**. The file contains all of the modifications you made to the signal groups, as well as the current data event log.

## **TCL Support**

To support automation, In-system Sources and Probes supports the procedures described in this chapter in the form of Tcl commands. The Tcl package for In-System Sources and Probes is included by default when you run **quartus\_stp**.

The Tcl interface for In-System Sources and Probes provides a powerful platform to help you debug your design. It is especially helpful for debugging designs that require toggling multiple sets of control inputs. You can aggregate multiple commands using a Tcl script to define your own custom command set.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. For more information about all settings and constraints in the Quartus II software, refer to the *Quartus II Settings File Reference Manual*. For more information about command-line scripting, refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook*.

Table 16–3 shows the Tcl command you can use with In-System Sources and Probes.

<b>Table 16–3. In-System Sources and Probes Tcl Commands</b>		
<b>Command</b>	<b>Argument</b>	<b>Description</b>
start_insystem_source_probe	-device_name <device name> -hardware_name <hardware name>	Opens a handle to a device using the specified hardware. Call this command before starting any transactions.
get_insystem_source_probe_instance_info	-device_name <device name> -hardware_name <hardware name>	Returns a list of all altsource_probe instances in your design. Each record returned will be in the following format: {<instance index>, <source width>, <probe width>, <instance name>}
read_probe_data	-instance_index <instance_index> -value_in_hex (optional)	Retrieves the current value of the probe. A string is returned specifying the status of each probe, with the MSB as the left-most bit.
read_source_data	-instance_index <instance_index> -value_in_hex (optional)	Retrieves the current value of the sources. A string is returned specifying the status of each source, with the MSB as the left-most bit.
write_source_data	-instance_index <instance_index> -value <value> -value_in_hex (optional)	Sets the value of the sources. A binary string is sent to the source ports, with the MSB as the left-most bit.
end_interactive_probe	None	Releases the JTAG chain. Issue this command when all transactions are finished.

Example 16–1 shows an excerpt from a Tcl script with procedures that control the altsource\_probe instances of the design as shown in Figure 16–5. The example design contains a DCFIFO with altsource\_probe instances to read from and to write to the DCFIFO. A set of control muxes are added into the design to control the flow of data to

the DCFIFO between the input pins and the `altsource_probe` instances. A pulse generator is added to the read request and write request control lines to guarantee a single sample read or write. The `altsource_probe` instances, when used with the script in [Example 16-1](#), provides visibility into the contents of the FIFO by performing single sample write and read operations and reporting the state of the full and empty status flags.

The Tcl script can be useful in debugging situations where you may want to either empty or preload the FIFO in your design. As an example, you can use this feature to preload the FIFO to match a trigger condition you have set up within the Signal Tap II Logic Analyzer.

**Figure 16-5. A DCFIFO Example Design Controlled by the Tcl Script in Example 16-1**

**Example 16–1. Tcl Script Procedures for Reading and Writing to the DCFIFO in Figure 16–5**

end_insystem_source_probe

return $x
}
```

---

## Design Example: Dynamic PLL Reconfiguration

The ease of use of the In-System Sources and Probes feature can be extremely helpful in creating a virtual front panel during the prototyping phase of your design. Relatively simple designs of high functionality can be created in a short amount of time. The following PLL reconfiguration example demonstrates how the In-System Sources and Probes feature is used to provide a GUI to dynamically reconfigure a Stratix PLL.

Stratix PLLs allows you to dynamically update PLL coefficients during run-time. Each enhanced PLL within the Stratix device contains a register chain that allows you to modify the pre-scale counters ( $m$  and  $n$  values), output divide counters, and delay counters. In addition, the `altpll_reconfig` megafunction provides an easy interface to access the register chain counters. The `altpll_reconfig` megafunction provides a cache containing all modifiable PLL parameters. After you have updated all of the PLL parameters in the cache, the `alt_pll_reconfig` megafunction drives the PLL register chain to update the PLL with the updated parameters. [Figure 16–6](#) shows a Stratix enhanced PLL with reconfigurable coefficients.

Stratix II and Stratix III devices also allow you to dynamically reconfigure PLL parameters. For more information about these families, refer to the appropriate data sheet. For more information about dynamic PLL reconfiguration, refer to *AN 282: Implementing PLL Reconfiguration in Stratix & Stratix GX Devices* or *AN 367: Implementing PLL Reconfiguration in Stratix II Devices*.

**Figure 16–6. Stratix-Enhanced PLL with Reconfigurable Coefficients**

The following design example uses an `altsource_probe` instance to update the PLL parameters in the `altpll_reconfig` megafunction cache. The `altpll_reconfig` megafunction connects to an enhanced PLL in a Stratix FPGA to drive the register chain containing the PLL reconfigurable coefficients. This design example uses a Tcl/Tk script to generate a GUI where you can enter new  $m$  and  $n$  values for the enhanced PLL. The Tcl script extracts the  $m$  and  $n$  values from the GUI, shifts the values out to the `altsource_probe` instances to update the values in the `altpll_reconfig` megafunction cache and asserts the reconfig signal on the `altpll_reconfig` megafunction. The reconfig signal on the `altpll_reconfig` megafunction

starts the register chain transaction to update all PLL reconfigurable coefficients. A block diagram of design example is shown in Figure 16–7. The Tk GUI is shown in Figure 16–8.

**Figure 16–7. Block Diagram of Dynamic PLL Reconfiguration Design Example**

**Figure 16–8. Interactive PLL Reconfiguration GUI Created with Tk and In-System Sources and Probes Tcl Package**

This design example was created using a NIOS® Development Kit, Stratix Edition. The file `sourceprobe_DE_dynamic_pll.zip` contains all of the necessary files for running this design example:

- **Readme.txt**—A text file that describes the files contained in the Design Example and provides instructions on running the Tk GUI shown in Figure 16–8.
- **Interactive\_Reconfig.qar**—The archived Quartus II project for this Design Example

You can download the `sourceprobe_DE_dynamic_pll.zip` file in the *Quartus II Handbook* volume 3 section of the Altera Literature web page.

## Conclusion

In-System Sources and Probes can provide stimuli and get responses from the target design during run-time. With its simple and intuitive interface, you can provide virtual inputs into your design during run-time without using external equipment. When used in conjunction with SignalTap II, you can use In-System Sources and Probes to provide greater control of the signals in your design, and thus help shorten the verification cycle. Also, with its ability to create virtual inputs into your design, you can create simple, yet powerful applications to interact with your design.

## Document Revision History

Table 16–4 shows the revision history for this chapter.

<b>Date and Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Reorganized “Referenced Documents” on page 16–21.	—
May 2007 v7.1.0	Initial Release.	—

---

The Quartus® II software easily interfaces with EDA formal design verification tools such as the Cadence Incisive Conformal and Synplicity Synplify software. In addition, the Quartus II software has built-in support for verifying the logical equivalence between the synthesized netlist from Synplicity Synplify and the post-fit Verilog Quartus Mapped (.vqm) files using Incisive Conformal software.

This section discusses formal verification, how to set-up the Quartus II software to generate the VQM file and Incisive Conformal script, and how to compare designs using Incisive Conformal software.

This section includes the following chapters:

- [Chapter 17, Cadence Encounter Conformal Support](#)
- [Chapter 18, Synopsys Formality Support](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

The Quartus® II software provides formal verification support for Altera® designs through interfaces with a formal verification EDA tool, the Cadence Encounter Conformal software.

Use the Encounter Conformal software to verify the functional equivalence of a post-synthesis Verilog Quartus Mapping netlist from the Synplicity Synplify Pro software and the post-fit Verilog Output File from the Quartus II software. You can also use the Encounter Conformal software to verify the functional equivalence of the register transfer level (RTL) source code and post-fit Verilog Output File from the Quartus II software when using Quartus II integrated synthesis. These formal verification flows support designs for the Cyclone®, Cyclone II, Stratix®, Stratix II, Stratix GX, Stratix II GX, Stratix III, Arria™ GX, and HardCopy® II device families.

There are two types of formal verification—equivalence checking and model checking. This chapter discusses equivalence checking using the Cadence Encounter Conformal software.

This chapter contains the following sections:

- “Formal Verification Design Flow” on page 17–2
- “RTL Coding Guidelines for Quartus II Integrated Synthesis” on page 17–5
- “Generating the Post-Fit Netlist Output File and the Encounter Conformal Setup Files” on page 17–10
- “Understanding the Formal Verification Scripts for Encounter Conformal” on page 17–18
- “Comparing Designs Using Encounter Conformal” on page 17–21
- “Known Issues and Limitations” on page 17–24
- “Black Box Models” on page 17–28
- “Conformal Dofile/Script Example” on page 17–30

Equivalence checking uses mathematical techniques to compare the logical equivalence of the two versions of the same design rather than using test vectors to perform simulation. The two compared versions could be post-map design and post-fit design, or RTL design and post-fit design. Equivalence checking greatly shortens the verification cycle of the design.

## Formal Verification Versus Simulation

Formal verification cannot be considered as a replacement to the vector-based simulation. Formal verification only complements the existing vector-based simulation techniques to speed up the verification cycle. Vector-based simulation techniques of gate level designs can take a considerable amount of time.

Vector-based simulation techniques can be used to do the following:

- Verify design functionality
- Verify timing specifications
- Debug designs

## Formal Verification: What You Need to Know

If you use formal verification techniques to verify logic equivalence of your design, you can save time by forgoing a comprehensive vector-based simulation of the gate level design. However, there may be impact on area and performance during recompilation of your design with the Quartus II software if you have chosen to use formal verification flow for Cadence Conformal LEC software. The area and performance of your design may be affected by the following factors:

- Hierarchy preservation
- ROM implementation by logic elements (LEs)
- Retiming is disabled

Refer to [“Known Issues and Limitations” on page 17–24](#) before you consider using the formal verification flow in your design methodology.

## Formal Verification Design Flow

Altera supports formal verification using the Encounter Conformal software for the following two synthesis tools:

- Quartus II Integrated Synthesis
- Synplify Pro

The following sections describe the supported design flows for these synthesis tools.

## Quartus II Integrated Synthesis

The design flow for formal verification using the Quartus II integrated synthesis is shown in Figure 17-1. This flow performs equivalency checking for the RTL source code and the post-fit netlist generated by the Quartus II software. The RTL source code can be in Verilog or VHDL format. The post-fit netlist generated by the Quartus II software is always in Verilog format.

**Figure 17-1. Formal Verification Using Quartus II Integrated Synthesis and the Encounter Conformal Software**

## EDA Tool Support for Quartus II Integrated Synthesis

The formal verification flow using the Quartus II software and Cadence Encounter Conformal software supports the following software versions and operating systems:

- Quartus II software beginning with version 4.2
- Cadence Encounter Conformal software beginning with 4.3.5A
- Solaris and Linux operating systems

## Synplify Pro

The design flow for formal verification using Synplify Pro Synthesis performs equivalency checking for the post-synthesis netlist from Synplify Pro and the post fit netlist generated by Quartus II software, as shown in Figure 17-2.

For additional information about performing equivalency checking between RTL and post-synthesis netlist generated from Synplify Pro software, refer to the Synplify Pro documentation.

## RTL Coding Guidelines for Quartus II Integrated Synthesis

The Cadence Encounter Conformal software can compare the RTL code against the post-fit netlist generated by the Quartus II software. The Encounter Conformal software and the Quartus II integrated synthesis parse and compile the RTL description in slightly different ways. The Quartus II software supports some RTL features that the Encounter Conformal software does not support, and vice versa. The style of the RTL code is of particular concern because neither tool supports some constructs, leading to potential formal verification mismatches; for example, state machine extraction, wherein different encoding mechanisms can result in different structures. Therefore, for successful verification, both tools must interpret the RTL code in the same manner.

The following section provides information on recognizing and preventing problems that can arise in the formal verification flow.

For more details about RTL coding styles for Quartus II Integrated Synthesis, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

Some of the coding guidelines apply to both Quartus II Integrated Synthesis and Synplify Pro flow, as indicated in each of the guidelines in the following sections.

### Synthesis Directives and Attributes

Synthesis directives, also known as pragmas, play an important role in successful verification of RTL against the post-fit Verilog Output netlist from the Quartus II software.

Pragmas and trigger keywords that are supported in Quartus II integrated synthesis and Encounter Conformal are also supported in the formal verification flow. The Quartus II integrated synthesis and Encounter Conformal both support the trigger keywords **synthesis** and **synopsys**. When the Quartus II software does not recognize a keyword such as **verplex**, the keyword is disabled in the formal verification scripts produced for use with the Cadence Conformal software. Therefore, it is important to use caution with unsupported pragmas because they can lead to verification mismatches.

For example, you can use the Quartus II integrated synthesis to synthesize RTL code with the synthesis directive `read_comments_as_HDL`.

**Example 17–1. Verilog HDL Example of Read Comments as HDL**

```
// synthesis read_comments_as_HDL on
// my_rom lpm_rom (.address (address),
// .data (data));
// synthesis read_comments_as_HDL off
```

**Example 17–2. VHDL Example of Read Comments as HDL**

```
-- synthesis read_comments_as_HDL on
-- my_rom : entity lpm_rom
-- port map (
-- address => address,
-- data => data, );
-- synthesis read_comments_as_HDL off
```

The Encounter Conformal software does not support the synthesis directive `read_comments_as_HDL`, and the directive has no affect on the Encounter Conformal software.

Table 17–2 lists supported pragmas and trigger keywords for formal verification.

<b>Pragmas (1)</b>	<b>Trigger Keywords</b>
full_case parallel_case pragma synthesis_off synthesis_on translate_off translate_on	synthesis synopsys

**Note to Table 17–2:**

- (1) Do not use Verilog 2001-style pragma declarations. The Quartus II software and the Encounter Conformal software support this style of pragma in different manners.

## Stuck-at Registers

Quartus II integrated synthesis eliminates registers that have their output stuck at a constant value. Quartus II integrated synthesis gives a warning message and adds an entry to the corresponding report panel in the formal verification folder of the Analysis and Synthesis section of the Compilation Report. If Conformal LEC does not find the same optimizations, it can lead to unmapped points in the golden netlist. Example 17-3 illustrates the issue:

---

### **Example 17-3. Verilog HDL Example Showing Stuck at Registers**

```
module stuck_at_example {clk, a,b,c,d,out};
input a,b,c,d,clk;
output out;
reg e,f,g;
    always @(posedge clk) begin
        e <= a and g;// e is stuck at 0
        g <= c and e;// g is stuck at 0
        f <= e | b;
    end
assign out = f and d;
endmodule
```

---

In this module description, registers `e` and `g` are tied to logic 0. In this example, the Quartus II software generates the following warning message:

```
Warning: Reduced register "g" with stuck data_in port to stuck value GND
Warning: Reduced register "e" with stuck data_in port to stuck value GND
```

Quartus II integrated synthesis then adds a command to the formal verification scripts telling Conformal LEC that a register is stuck at a constant value, as shown in Example 17-4:

---

### **Example 17-4. Conformal LEC Script Showing Commands for Instance Equivalence**

```
// report floating signals
// Instance-constraints commands for constant-value registers removed
// during compilation
// add instance constraints 0 e -golden
// add instance constraints 0 g -golden
```

---

The command is commented in the formal verification script, forcing the Encounter Conformal software to treat the register as stuck at a constant value, and potentially hiding a compilation error. You must verify that input to the `e` and `g` registers is constant in the design and uncomment the command to obtain accurate results.

Altera recommends recoding your design to eliminate “stuck-at” registers.

The stuck-at register information in this section also applies to the Synplify Pro flow.

## ROM, LPM\_DIVIDE, and Shift Register Inference

For the purpose of formal verification, the Quartus II integrated synthesis implements both ROM and shift registers in the form of LEs instead of using dedicated on-chip memory resources. Using LEs can be less area-efficient than inferring a megafunction that can be implemented in a RAM block. However, the Quartus II software generates a warning message indicating that the megafunction was not inferred. Quartus II integrated synthesis also reports a suggested ROM or shift register instantiation that enables you to either use the MegaWizard® Plug-In Manager to create the appropriate megafunction explicitly, or to isolate the corresponding logic in a separate entity that you can set as a black box. By setting black box properties on a particular module or entity, you are telling the formal verification tool not to peek inside the module or entity for formal verification. If the black box properties are set on the corresponding megafunction before synthesis, you can verify the megafunction with the Encounter Conformal software.

If the design contains division functionality, the Quartus II software infers an `lpm_divide` megafunction, which is treated as a black box for the purpose of formal verification.

## RAM Inference

When the Quartus II software infers the LPM megafunction `altsyncram` from the RTL code, the Quartus II software generates the following warning message:

```
Created node "<mem_block_name>" as a RAM by generating altsyncram megafunction to implement register logic with M512 or M4K memory block or M-RAM. Expect to get an error or a mismatch for this block in the formal verification tool.
```

This warning is generated because the memory block (`altsyncram`) is a new instance in the post-fit netlist that is handled as a black box by the formal verification tool. However, no such instance exists in the original RTL design, resulting in mismatch or error reporting in the formal verification tool.

## Latch Inference

A latch is implemented in the Quartus II integrated synthesis using a combinational feedback loop. The Encounter Conformal software infers a latch primitive in the Encounter Conformal library (DLAT) to implement a latch. This results in having a DLAT on the golden side and a combinational loop with a cut point on the revised side, leading to verification mismatches. The Quartus II software issues a warning message whenever a latch is inferred, and the Quartus II software adds an entry to the report panel in the Formal Verification folder of the Analysis and Synthesis report. Altera recommends that you avoid latches in your design; however, if latches are necessary, Altera recommends using the corresponding `lpm_latch` megafunction.

For more information about the problems related to latches, refer to the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook*.

## Combinational Loops

If the design consists of an intended combinational loop, you must define an appropriate cut point for both the RTL and the post-fit Verilog Output netlist. A warning that a combinational loop exists in the design is found in the Formal Verification subfolder of the Quartus II software Analysis and Synthesis report.

For more information on issues with combinational loops, see [“Known Issues and Limitations”](#) on page 17–24.

## Finite State Machine Coding Styles

When a state machine is inferred by the Encounter Conformal software, it uses sequential encoding as the default encoding when no user encoding is present. The Quartus II software selects the encoding most suited for the inferred state machine if the State Machine Processing Settings on the **Analysis and Synthesis Settings** page of the **Settings** dialog box is set to the default value **Auto**. Therefore, it is important to use the coding style described in the *Recommended HDL Coding Styles* chapter in volume 1 of the *Quartus II Handbook* on RTL when writing finite state Machines (FSMs). This allows the Quartus II integrated synthesis and the Encounter Conformal software to infer a similar state machine for the same RTL code.

## Generating the Post-Fit Netlist Output File and the Encounter Conformal Setup Files

The following steps describe how to set up the Quartus II software environment to generate the post-fit Verilog Output netlist and the Encounter Conformal script for use in formal verification. With the exception of step 3, the steps are identical for both of the Synthesis tools:

1. Create a new Quartus II project or open an existing project.
2. On the Assignments menu, click **EDA Tool Settings**. The **Settings** dialog box appears.
3. In the **Category** list, click **EDA Tool Settings**.

If you are using the Quartus II integrated synthesis, perform the following steps:

- a. In the **Category** list, under **EDA Tool Settings**, select **Design Entry/Synthesis**. Select **<None>** from the Tool name list.
- b. In the **Category** list, under **EDA Tool Settings**, select **Formal Verification**. Select **Conformal LEC** from the Tool name list (Figure 17-3).

**Figure 17–3. Compilation Process Settings**

If you are using Synplify Pro, perform the following steps:

- a. In the **Category** list, under **EDA Tool Settings**, select **Design Entry/Synthesis**. Select **Synplify Pro** from the Tool name list.
  - b. In the **Category** list, under **EDA Tool Settings**, select **Formal Verification**. Select **Conformal LEC** from the Tool name list.
4. In the **Category** list, select **Compilation Process Settings**. Under **Compilation Process Settings**, select **Incremental Compilation**.

In the **Incremental Compilation** page, click **Full Incremental Compilation** to turn on Incremental Compilation.

*or*

Turn on Incremental Compilation by typing the following Tcl command in the Quartus II software Tcl console:

---

**Example 17–5. Tcl Command to Turn On Full Incremental Compilation**

```
set_global_assignment -name INCREMENTAL_COMPILATION \  
FULL_INCREMENTAL_COMPILATION
```

---

Altera requires that Incremental Compilation be turned **On** for Formal Verification, and that your design does not contain any user created partitions. Starting with Quartus II version 6.1 and later, the incremental compilation feature is **On** by default.

5. In the **Category** list, select **Analysis and Synthesis Settings** to expand the options list, and click **Synthesis Netlist Optimizations**. In the **Synthesis Netlist Optimizations** page, turn off **Perform gate-level register retiming** (Figure 17–4).

If **Perform gate-level register retiming** is not turned off, the Encounter Conformal script can display a different set of compare points, making the resulting netlist difficult to compare against the reference netlist file.

**Figure 17–4. Synthesis Netlist Optimizations**

6. In the **Category** list, select **Fitter Settings**, and select **Physical Synthesis Optimizations**.
  - a. Under **Physical synthesis for registers**, turn off **Perform register retiming**.
  - b. Under **Physical Synthesis for Fitting**, turn off both **Perform physical synthesis for combinational logic** and **Perform logic to memory mapping** to prevent logic from being mapped to RAMs (Figure 17–5).

Figure 17–5. Fitter Settings

Retiming a design, either during the synthesis step or during the fitting step, usually results in moving and merging registers along the critical path and is not well supported by the equivalence checking tools. Because equivalence checkers compare the cone of logic terminating at registers, do not use retiming to move the registers during optimization in the Quartus II software.

If the options **Perform gate-level register retiming** (Figure 17–4) and **Perform register retiming** (Figure 17–5) are not turned off, the Encounter Conformal script can display a different set of compare points, making the resulting netlist difficult to compare against the reference netlist file. If you use retiming in your design during compilation, then you cannot generate a netlist for formal verification.

To learn more about physical synthesis, refer to the *Netlist Optimizations and Physical Synthesis* chapter in volume 2 of the *Quartus II Handbook*.

7. Perform a full compilation of the design. On the Processing menu, click **Start Compilation**, or click the **Start Compilation** icon on the Toolbar.

If your golden netlist (VQM netlist from Synplify Pro or RTL) includes any design entity not having a corresponding formal verification model, that entity is handled as a black box whose boundary interface is preserved. There are three types of black boxes and required user actions, depending upon each circumstance. [Table 17-3](#) describes these three types of black boxes and the required user actions in detail.

<b>Table 17-3. Black Boxes and Required User Action</b>	
<b>Type of Black Box</b>	<b>Required User Action</b>
Altera library of parameterized modules (LPMs) and megafunctions (refer to <a href="#">Table 17-5</a> for a complete list).	No action required. The Quartus II software automatically black boxes the list of components and preserves the hierarchy.
Any parameterized entity other than those listed in <a href="#">Table 17-5</a> .	User must black box the wrapper that instantiates the parameterized entity.
Non parameterized entities that the user wants to black box.	User can black box the entity itself.

You can also use Tcl commands or Quartus II GUI to set the black box property on the entities, which the formal verification tool does not compare.

#### *Tcl Command*

Use the following Tcl commands to preserve the boundary interface of a black box entity: dram.

#### **Example 17-6. Tcl Command to Create a Black Box**

```
set_instance_assignment -name PRESERVE_HIERARCHICAL_BOUNDARY FIRM -to | -entity dram
set_instance_assignment -name EDA_FV_HIERARCHY BLACKBOX -to | -entity dram
```

#### *GUI*

To preserve the boundary interface of an entity using the GUI, follow these steps:

1. Make an EDA Formal Verification Hierarchy assignment to the entity with the value BLACKBOX.

2. Make a Preserve Hierarchical Boundary assignment to the entity with the value `Firm` (Figure 17-6).

**Figure 17-6. Setting the Black-Box Property on a Module**

## The Quartus II Software Generated Files, Formal Verification Scripts, and Directories

After successful compilation, the Quartus II software generates a list of files, formal verification scripts, and directories in the `<project_directory>fv/conformal/` directory (Table 17-4).

**Table 17-4. The Quartus II Software Compiler-Generated Files and Directories (Part 1 of 2)**

File or Directory	Name	Details
Verilog Output File	<code>&lt;proj_rev&gt;.vo</code>	The Quartus II software-generated netlist for formal verification.

**Table 17–4. The Quartus II Software Compiler-Generated Files and Directories (Part 2 of 2)**

File or Directory	Name	Details
Script file	<code>&lt;proj rev&gt;.ctc</code>	The <code>&lt;proj rev&gt;.ctc</code> file references <code>&lt;proj rev&gt;.clg</code> and <code>&lt;proj rev&gt;.clr</code> that read the library files and black box descriptions. The <code>&lt;proj rev&gt;.ctc</code> file also references the <code>&lt;proj rev&gt;.cmc</code> file containing information about the mapped points. (1)
	<code>&lt;proj rev&gt;.cec</code>	The <code>&lt;proj rev&gt;.cec</code> file contains the information for instance equivalences.
	<code>&lt;proj rev&gt;.cep</code>	The <code>&lt;proj rev&gt;.cep</code> file contains the information for black box pin equivalences in the design.
	<code>&lt;proj rev&gt;.cmp</code>	The <code>&lt;proj rev&gt;.cmp</code> file contains the information for the black box pin mapping between the golden and revised sides. (2)
	<code>&lt;proj rev&gt;.cmc</code>	The <code>&lt;proj rev&gt;.cmc</code> file contains information about the additional points to be mapped in addition to the points selected by the tool.
	<code>&lt;proj rev&gt;_trivial.cmc</code>	This <code>&lt;proj rev&gt;_trivial.cmc</code> file contains mapping information for all the key points in the design. (3)
	<code>&lt;proj rev&gt;.clr</code>	The <code>&lt;proj rev&gt;.clr</code> file contains information about the macros and libraries for the revised design.
	<code>&lt;proj rev&gt;.clg</code>	The <code>&lt;proj rev&gt;.clg</code> file contains information about the macros and libraries for the golden design.
<b>blackboxes</b> directory	<code>&lt;project directory&gt;/fv/conformal/&lt;project rev&gt;_blackboxes</code>	This directory contains top-level module descriptions for all the user-defined black box entities and contains modules with definitions other than Verilog or VHDL, for example, Block Design File (.bdf) in the design directory <code>&lt;project directory&gt;/fv/conformal/&lt;project rev&gt;_blackboxes</code>

**Notes to Table 17–4:**

- (1) This file is used with the Encounter Conformal software.
- (2) This file is called from the `<proj rev>.ctc` script file. By default, the line where this file is called is commented out. These files are only useful for HardCopy II device families.
- (3) In some cases, Encounter Conformal software performs incorrect key point mapping, resulting in formal verification mismatches. To overcome the verification mismatches, the Quartus II software writes out the `<proj rev>_trivial.cmc` file that contains mapping information for all the key points in the design. Reading this file during the formal verification setup can result in increased run time. Therefore, the Quartus II software writes out the top-level script file `<proj rev>.ctc` with the command to read the `<proj rev>_trivial.cmc` file commented. If the formal verification results are not acceptable, the user can uncomment the command and read the `<proj rev>_trivial.cmc` file. The command in the `<proj rev>.ctc` file is:

```
//Trivial mappings with same name registers
//read mapped points $PROJECT/fv/conformal/<proj rev>_trivial.cmc
```

The script file contains the setup and constraints information to be used with the formal verification tool. The file `<entity>.v` in the **blackboxes** directory contains the module description of entities that are not defined in the formal verification library. The file also contains entities that you

specify as black boxes. For example, if there is a reference to a black box for an instance of the `altdpram` megafunction in the design, the **blackboxes** directory does not contain a module description for the `altdpram` megafunction because it is defined in the `altdpram.v` file of the formal verification library. When a module does not have an RTL description, or the description exists only in the formal verification library and you do not want to compare the module using formal verification, a file containing only the top-level module description with port declaration is written out to the **blackboxes** directory and read into the Encounter Conformal software.

## Understanding the Formal Verification Scripts for Encounter Conformal

The Quartus II software generates scripts to use with the Encounter Conformal Logic Equivalence Check (LEC) software. This section elaborates on the details of the Encounter Conformal commands used within the scripts to help you compare the revised netlist with the golden netlist. In most cases, you do not need to add any more Encounter Conformal constraints to verify your netlists. Also, a sample script generated by the Quartus II software is provided at the end of the chapter.

### The Encounter Conformal Commands within the Quartus II Software-Generated Scripts

The value for the variable `QUARTUS` is the path to the Quartus II software installation directory:

```
setenv QUARTUS <Quartus Installation Directory>
```

The Quartus II software assigns the current working directory of the project to the `PROJECT` variable. Use this variable to change the project directory to the directory where the design files are installed when moving from a UNIX to a Windows environment, or vice versa:

```
setenv PROJECT <Quartus Project Directory>
```

The following command reads both the golden and the revised netlists, along with the appropriate library models:

```
read design <design files>
```

You must update the project location when the files are moved from the Windows environment to the UNIX environment.

The post place-and-route netlist from the Quartus II software might contain net and instance names that are slightly different from those of the golden netlist. By using the following command, the Quartus II

software defines temporary substitute string patterns enabling the Encounter Conformal software to automatically map key points when the names are not the same:

```
add renaming rule <rule>
```

The Encounter Conformal LEC software employs three name-based methods to map key points to compare the revised netlist with the golden netlist. Scripts set the correct method to get the best results.

```
set mapping method <mapping_rule>
```

The Quartus II software performs several optimizations, including optimizing the registers whose input is driven by a constant. Under these circumstances, for the formal verification software to compare the netlists properly, the command `set flatten model` is used with the option `seq_constant`.

```
set flatten model <flattening_rule>
```

When you use the command `report black_box`, verify that the following modules are listed as black boxes, along with any of the modules black boxed by the user, in both the golden and revised netlists:

- LPMs and megafunctions without the formal verification models
- Encrypted IP functions
- Entities not implemented in Verilog HDL or VHDL

Use the following command to set the same implementation on multipliers for both the golden and revised netlists:

```
set multiplier implementation <implementation_name>
```

If there are any combinational loops or instances of `LPM_LATCH`, the Quartus II software cuts the loop at the same point using the following command on both the golden and revised netlists:

```
add cut point
```

The Encounter Conformal software does not always automatically map all the keypoints, or can incorrectly map some keypoints. To help the Encounter Conformal software successfully complete the mapping process, the Quartus II software records optimizations performed on the netlist as a series of `add mapped points` in the Encounter Conformal `<file_name>.cmc` script.

```
add mapped points <key_points>
```

There are situations where the inverter in front of the register gets moved after the register. In this situation, the following command is used:

```
add mapped points <key_points> -invert
```

The following command reads in the mapped point information from the specified file:

```
read mapped points <file_name>.cmc
```

**Figure 17-7. Instance Equivalence**

During the process of optimization, the Quartus II software might merge two registers into one (Figure 17-7). The Quartus II software informs the formal verification tool that the U1 and U2 registers are equivalent to each other using the following command:

```
add instance equivalence <instance_pathname ..> [-Golden]
```

If the register duplication takes place, the following command is used:

```
add instance equivalence <instance_pathname ..>
[-revised]
```

The following command is used when the inverter is moved beyond the register along with either register duplication or merging:

```
add instance equivalences <instance_pathname>
[-invert <instance_pathname>]
```

At times, the register output is driven to a constant, either `logic 0` or `logic 1`. The Quartus II software sets the value of the register to a constraint using the `add instance constraint` command. For more information about this command, refer to “[Stuck-at Registers](#)” on page 17–7.

```
add instance constraint <constraint_value>
```

## Comparing Designs Using Encounter Conformal

This section addresses using the Encounter Conformal software to compare designs; that is, how to prove logical equivalence between two versions of the design.

### Black Boxes in the Encounter Conformal Flow

The Quartus II software usually generates a flattened netlist. However, there are some modules in the design that must be treated differently. The following is a list of some of these modules:

- LPMs and megafunctions without formal verification models
- Encrypted IP functions
- Entities not implemented in Verilog HDL or VHDL

To perform equivalence checking of a design between its version consisting of the modules listed above and its implemented version, the modules have to be treated as black boxes by the Encounter Conformal software. To facilitate the formal verification flow, the Quartus II software reconstructs the hierarchy on the black boxes with a port interface that is identical to the module on the golden side of the design.

Verilog Output netlist files written by the Quartus II software also contain the black box hierarchy when you make the following assignments for a module:

- An EDA Formal Verification Hierarchy assignment with the value `BLACKBOX`
- A Preserve Hierarchical Boundary assignment with the value `Firm` ([Figure 17–6](#))

If these two assignments are not made for a module, the Quartus II software implements that module with logic cells. When this happens, the Verilog Output netlist file no longer contains the black box hierarchy and does not preserve the port interface, resulting in a mismatch within the Encounter Conformal software.

## Running the Encounter Conformal Software

To run the Encounter Conformal software, use its GUI or a system command prompt, and use the CTC script generated by the Quartus II software.

### *Running the Encounter Conformal Software from the GUI*

To run the Encounter Conformal software from the GUI, follow these steps:

1. Open the Encounter Conformal software.
2. On the File menu, click **Do Dofile**.
3. Select the file *<path to project directory>/fv/conformal/<proj rev>.ctc*.

The Encounter Conformal software GUI displays the comparison results (Figure 17-8). The Golden window displays the original RTL description or the post synthesis VQM netlist from Synplify Pro, and the Revised window displays the information of the post-fit netlist generated by the Quartus II software. The message section at the bottom of the window reports the verification results and the number of unmapped and non-equivalent points found in the design.

**Figure 17–8. Encounter Conformal Software GUI Display of Functional Comparisons**

To investigate the verification results, click the **Mapping Manager** icon in the toolbar, or on the Tools menu, click **Mapping Manager**. The Encounter Conformal software reports the mapped, unmapped, and compared points in the Mapped Points, Unmapped Points, and Compared Points windows, respectively.

For more information about how to diagnose non-equivalent points, refer to the Encounter Conformal software user documentation.

## Running the Encounter Conformal Software From a System Command Prompt

To run the Encounter Conformal Software without using the GUI, type the command shown in Example 17-7 at a system command prompt.

---

### Example 17-7. Conformal LEC Command to Run Formal Verification

```
lec -dofile /<path to project directory>/fv/conformal/<proj rev>.ctc -nogui ←
```

---

To get a downloadable design example showing the formal verification flow with Quartus II software, go to [www.altera.com/support/examples/quartus/exm-formal-verification.html](http://www.altera.com/support/examples/quartus/exm-formal-verification.html).

To learn more about the latest debugging tips and solutions for formal verification flow between Cadence Conformal LEC tool and Quartus II software, go to [www.altera.com](http://www.altera.com) and perform an advanced search with keywords “formal verification.”

## Known Issues and Limitations

The following known issues and limitations can occur when using the formal verification flow described in this chapter:

- When a port on a black box entity drives two or more signals within the black box, the Quartus II software pushes the connections outside of the black box, and creates that many ports on the black box. This problem is only associated with Stratix II and HardCopy II designs.

The additional ports on the black box are named `_unassoc_inputs_[]` and `_unassoc_outputs_[]` (Figure 17-9). This issue is generally associated with reset and enable signals. Figure 17-9 shows an example in which the reset pin is split into two ports outside of the black box and the `_unassoc_inputs_[]` is driven by the `clkctrl` block. In such situations, the Verilog Output netlist generated by the Quartus II software has signals driving these black box ports, but golden RTL does not contain any signals to drive the `_unassoc_inputs_[]`, resulting in a formal verification mismatch of the black box. The black box module definition generated by the Quartus II software in the directory `<Quartus_project>\fv\conformal\*_blackboxes` contains these additional `_unassoc_inputs_[]` and `_unassoc_outputs_[]` ports. This black box module is read on

both the golden and revised sides of the design, which results in unconnected ports on the golden side and formal verification mismatches.

Figure 17-9 shows the creation of `_unassoc_inputs_[]` and `_unassoc_outputs_[]` for the reset signal.

**Figure 17-9. Creation of `_unassoc_inputs_[]` and `_unassoc_outputs_[]`**

Another common occurrence of this issue is in HardCopy II designs. Whenever a port drives large fan-out within the black box, the Quartus II software inserts a buffer on the net and moves the logic outside of the black box (Figure 17-10).

To fix the problem of `unassoc_input_[]` ports causing blackbox mismatches, use Cadence Conformal commands to change the type of the blackbox `unassoc_input_[]` keypoint to a primary output keypoint, and then marking the appropriate pin equivalences. Similarly, to fix the problem of register mismatches due to `unassoc_output_[]` pins from blackboxes, use Conformal commands to change the type of the blackbox `unassoc_output_[]` keypoint to a primary input, and then marking equivalent pins as such. The commands to perform these actions are written in the `<proj rev>.cep` file.

Figure 17-10 shows the creation of `_unassoc_inputs_[]` for a signal with large fan-out.

**Figure 17-10. Creation of `_unassoc_inputs_[]` for a Signal with Large Fan-out**

- In designs with combinational feedback loops, the Encounter Conformal software can insert extra cut points in the revised netlist, causing unmapped points and ultimately verification mismatches.
- For Cyclone II designs, Conformal LEC may report non-equivalent flipflops and extra cut points for the revised (post-fit) design when your HDL source code instantiates the `lpm_ff` primitive with an asynchronous load signal `aLoad` (with or without any other asynchronous control signals) and when the asynchronous clear signal `aclr` and asynchronous set signal `aset` are used together. To avoid this problem, ensure that there is a wrapper module or entity around the `lpm_ff` instantiation, and black box the module or entity that instantiates the `lpm_ff` primitive.
- For Stratix III designs, the Cadence Conformal LEC software creates cut points for the combinational loops on the golden side and may fail equivalence checking due to improper mapping. The combinational loops are due to logic around the registers emulating multiple set, resets, or both. These cut points are also reported during the mapping step in Quartus II software with Warning messages. You can manually add Cadence Conformal commands to add cut points, which result in proper mapping and formal verification.
- To perform formal verification, certain synthesis optimization options, such as register retiming, optimization through black box hierarchy boundaries, and disabling the ROM and shift register inference, are turned off, which can have an impact on the area resource and performance.
- RAM and ROM instantiations, inferences, or both are not verified using formal verification.

- Incremental Compilation for the purpose of formal verification does not support user-created design partitions.
- Formal verification does not support clear box netlist due to unconnected ports on its WYSIWYG instances.
- Formal verification does not support VHDL megafunction variations due to undriven ports on the megafunctions.
- When a black box contains bidirectional ports, the Quartus II software fails to reconstruct the hierarchy. For this reason, the black box is represented by a flat netlist, resulting in formal verification mismatches.
- ROMs in the design have to be black boxed before compilation using Quartus Integrated Synthesis, because the Quartus II software may perform some optimizations on the ROM, resulting in Formal Verification mismatches.
- Conformal may report mismatches or abort comparison of some key points when a DSP megafunction is implemented in LEs by the Quartus II software due to implicit optimizations within the DSP and the complexity of the multiplier logic in terms of LEs.
- Unused logic optimized within and around a black box by the Quartus II software can result in a black-box interface different from the interface in the synthesized VQM netlist.

## **Conclusion**

Formal verification software enables verification of the design during all stages from RTL to placement and routing. Verifying designs takes more time as designs increase in size. Formal verification is a technique that helps reduce the time needed for your design verification cycle.

## Black Box Models

The black box models are interface definitions of entities, such as primitives, atoms, LPMs, and megafunctions. These models have a parameterized interface, and do not contain any definition of behavior. They are specifically designed and tested to work with the Encounter Conformal software, which uses these models along with your design to generate black boxes for instances of the entity with varying sets of parameters in the design. [Table 17-5](#) describes the supported black box models. Besides these black box models, you can set a black box property on a specific module or entity as explained earlier in this chapter.

**Table 17-5. Supported Black Box Models (Part 1 of 3)**

Entity Type	Entity Names
Megafunctions	alt3pram, altaccumulate, altfp_mult, altsqrt, altlvds_rx, altlvds_tx, altshift_taps, sld_virtual_jtag sld_virtual_jtag_basic dcfifo, scfifo, altsyncram, altsqrt
LPMs	lpm_add_sub, lpm_divide

**Table 17–5. Supported Black Box Models (Part 2 of 3)**

Entity Type	Entity Names
Atoms (1)	Cyclone: cyclone_crcblock, cyclone_jtag, cyclone_pll, cyclone_ram_block, cyclone_asmiblock, cyclone_dll
	Stratix: stratix_crcblock, stratix_jtag, stratix_lvds_receiver, stratix_lvds_transmitter, stratix_pll, stratix_rublock, stratix_ram_block, stratix_dll
	Stratix II: stratixii_crcblock, stratixii_jtag, stratixii_lvds_receiver, stratixii_lvds_transmitter, stratixii_pll, stratixii_rublock, stratixii_ram_block, stratixii_asm_block, stratixii_dll, stratixii_termination, stratixii_asmiblock
	Stratix GX: stratixgx_crcblock, stratixgx_jtag, stratixgx_lvds_receiver, stratixgx_lvds_transmitter, stratixgx_pll, stratixgx_rublock, stratixgx_ram_block, stratixgx_dll
	Stratix II GX: stratixiigx_hssi_receiver, stratixiigx_hssi_transmitter, stratixiigx_hssi_central_management_unit, stratixiigx_hssi_cmu_pll, stratixiigx_hssi_cmu_clock_divider, stratixiigx_hssi_refclk_divider, stratixiigx_hssi_calibration_block, stratixiigx_crcblock, stratixiigx_ram_block, stratixiigx_lvds_transmitter, stratixiigx_lvds_receiver, stratixiigx_pll, stratixiigx_dll, stratixiigx_jtag, stratixiigx_asmiblock, stratixiigx_termination, stratixiigx_rublock
	Cyclone II: cycloneii_asmiblock, cycloneii_clk_delay_ctrl, cycloneii_clkctrl, cycloneii_jtag, cycloneii_pll, cycloneii_ram_block

## Introduction

Formal verification of FPGA designs is gaining momentum as multi-million System-on-a-Chip (SoC) designs are targeted at FPGAs. Use the Formality software to easily verify logic equivalency between the RTL and DC FPGA post-synthesis netlist, and between the DC FPGA post-synthesis netlist and Quartus II post-place-and-route netlist. Beginning with version 4.2, the Quartus® II software interfaces with EDA tools including the Formality and DC FPGA software from Synopsys.

This chapter discusses the following:

- [“Formal Verification”](#)
- [“Formal Verification Support”](#) on page 18–2
- [“Generating Post-Synthesis Netlist for Formal Verification”](#) on page 18–3
- [“Generating the VO File and Formality Script”](#) on page 18–4
- [“Quartus II Scripts for Formality”](#) on page 18–11
- [“Comparing Designs Using the Formality Software”](#) on page 18–11
- [“Known Issues and Limitations”](#) on page 18–12

## Formal Verification

Formal verification uses exhaustive mathematical techniques to verify design functionality. There are two types of formal verification: equivalence checking and model checking. This section discusses equivalence checking.

### Equivalence Checking

Equivalence checking compares the logical equivalence between the original design and the modified or revised design using mathematical techniques. This method reduces the verification time several-fold compared to the traditional method of performing verification using test vectors. Using a formal verification methodology provides the following key advantages:

- Faster time-to-market
- No testbenches or test vectors
- Results in hours compared to days using traditional verification methods

## Formal Verification Support

The Quartus II software supports formal verification using the Formality software for the DC FPGA Synthesis tool as shown in Figure 18–1.

Figure 18–1. Equivalence Checking in the FPGA Design Flow

### EDA Tools and Device Support

The formal verification flow using the Quartus II software and Synopsys Formality software requires the following software versions:

- Quartus II software, beginning with version 4.2
- Synopsys DC FPGA software, beginning with version W2005.03\_EA1
- Synopsys Formality software, beginning with version 2004.12

The formal verification flow, using the Quartus II and Synopsys Formality software, supports Solaris and Linux platforms, and supports Stratix series devices.

### Formal Verification Between RTL and Post-Synthesis Netlist

The first step in the FPGA design flow is to synthesize the RTL code using the DC FPGA to generate the synthesized verilog netlist. Equivalence checking using formal verification is performed between the RTL and the synthesized netlist to make sure the synthesis tool has not altered the original functionality of the design.

## Generating Post-Synthesis Netlist for Formal Verification

For more information on how to use the DC FPGA software for synthesizing Altera device designs, refer to the *Synopsys Design Compiler FPGA Support* chapter in volume 1 of the *Quartus II Handbook*.

During the synthesis process, the DC FPGA synthesis tool performs operations such as:

- Modifying the net/instance names
- Register duplication
- State machine extraction by different methods

Changes caused by these synthesis operations cause comparison point matching issues and false verification failures. In order to make sure that the Formality software is aware of the design transformations performed during the synthesis, the DC FPGA software writes out a Synopsys setup verification file (**.svf**) to be read into the Formality software. To ensure the SVF constraint file contains all the formal verification setup constraints, you need to set certain commands in the DC FPGA software before compiling the design as detailed in the following section.

### DC FPGA Software Settings

The Formality software does not support the **register merging** or **register retiming** synthesis operations, which are off by default, but it is necessary to verify that these settings are turned off during synthesis. Some of the commands necessary to turn off these options and generate a valid Verilog netlist for the formal verification purpose are described in this section.

For more information on creating the Tcl script file to perform synthesis, refer to the *DC FPGA User Guide* or the *Synopsys Design Compiler FPGA Support* chapter in volume 1 of the *Quartus II Handbook*.

To set most of the required synthesis settings to generate a valid formal verification netlist, use the following command:

```
set_fpga_defaults -formality <architecture_name>
```

For example:

```
set_fpga_defaults -formality altera_stratix
```

To view all of the settings performed by this command, add `-verbose` to this command. In addition, you will need to execute the additional commands shown in [Table 18-1](#).

<b>Command</b>	<b>Affect</b>
<code>set verilout_write_constant_nets true</code>	Add this command at the beginning of the script to allow unconnected nets to be driven by either power or ground.
<code>change_names -rule verilog -hierarchy</code>	This command must be added after the compile command to set the Verilog naming rule to the output netlist for all levels of hierarchy.
<code>set_verification_friendly_mode -filename \ &lt;top_level&gt;.svf -append -allow_override</code>	This command helps DC_FPGA to write out a SVF constraint file to be read into the Formality software.
<code>write -hier -f verilog -o \$outputdir/&lt;top_level&gt;.v</code>	This command writes out a Verilog netlist for Formal Verification.

For a sample DC FPGA script that is ready for compilation, refer to “[Tcl Sample Script](#)” on page 18-13.

Post synthesis Verilog netlist for formal verification can be generated by executing the Tcl script either in `fpga_vision` (GUI) or `fpga_shell -t` (command line).

For comparing RTL against post-synthesis netlist using the Formality software, refer to the *DC FPGA Software User Guide*.

## Generating the VO File and Formality Script

The following steps describe how to set up the Quartus II software environment to generate the place-and-route, post-place-and-route VO netlist file, and Formality script compatible for formal verification.

1. Create a new Quartus II project or open an existing project.
2. On the Assignments menu, click **Settings**. The **Settings** dialog box is shown.
3. In the Category list, select **Files**. The **Files** page is shown.
4. Highlight the input file by clicking on it, then click **Properties** and select **Verilog Quartus Mapping File**. Click **OK**.

5. In the **Category** list, select **Design entry/synthesis** under **EDA Tool Settings**.
6. In the **Tool name** list, select **Design Compiler FPGA** (Figure 18–2).

These settings can also be performed using the following Tcl commands:

```
set_global_assignment -name VQM_FILE
<verilog_file_from_dc_fpga>
```

```
set_global_assignment -name \
EDA_DESIGN_ENTRY_SYNTHESIS_TOOL "Design Compiler FPGA"
```

```
set_global_assignment -name EDA_LMF_FILE \
dc_fpga.lmf -section_id eda_design_synthesis
```

**Figure 18–2. EDA Tools Selection**

7. In the **Category** list, select **Formal verification**. In the **Tool name** list, select **Formality** (Figure 18–3).

**Figure 18–3. EDA Tools Selection**

8. Click **OK**.
9. From the Assignments menu, click **Settings**. The **Settings** dialog box is shown.
10. In the **Category** list, click the + icon to expand **Analysis and Synthesis Settings** and select **Synthesis Netlist Optimizations**. The **Synthesis Netlist Optimizations** page is shown.

- Turn off the **Perform gate-level register retiming** option (Figure 18–4).

**Figure 18–4. Synthesis Netlist Optimizations**

- In the Category list, click the + icon to expand **Fitter Settings** and select **Physical Synthesis Optimizations**. The **Physical Synthesis Optimizations** page is shown.

13. Turn off the **Perform register retiming** option (Figure 18–5).

**Figure 18–5. Setting Parameters for Netlist Optimizations**

Performing register retiming on a design usually results in moving and merging/duplicating registers along the critical path. Because equivalence checkers compare the cones of logic terminating at registers, you should not move or duplicate the registers during optimization by the Quartus II software. If the options in this section are not selected, the Formality software script could be presented with a different set of compare points, and the resulting netlist is difficult to compare against the reference netlist file.

The Quartus II software, beginning with version 4.2, supports register duplication to improve the timing by duplicating the logic.

To learn more about register duplication, refer to the *Analyzing and Optimizing the Design Floorplan* chapter in volume 2 of the *Quartus II Handbook*.

14. Perform a full compilation of the design either on the Processing menu by clicking **Start Compilation** or by clicking on the start compilation arrow icon located in the tool bar.

## Handling Black Boxes

Every design entity in the golden netlist must have a corresponding formal verification model in order to successfully run formal verification. Design entities in the golden netlist without a corresponding formal verification model are handled as black boxes whose boundary interfaces must be preserved. These design entities appear in the netlist if one of the following situations apply:

- Altera megafunctions including library of parameterized modules (LPM's)
  -  The black-box property is only applied to LPM modules that do not have a formal verification model.
- Encrypted intellectual property (IP) cores
- Entities that are defined in the design format other than Verilog HDL or VHDL

The Quartus II software has the capability of automatically identifying the black boxes and sets the property Preserve Hierarchical Boundary to Firm to preserve the boundary interfaces of the black boxes which helps the formal verification.

You can also specify the black box property on entities that should be compared by the Formality software. To do this make the following assignments either using Tcl commands or GUI for the entities in question:

### *Tcl Command*

The following two commands preserves the boundary interface of the entity: dram.

```
set_instance_assignment -name\
PRESERVE_HIERARCHICAL_BOUNDARY FIRM -to | -entity dram
set_instance_assignment -name EDA_FV_HIERARCHY\
BLACKBOX -to | -entity dram
```

## GUI

Preserving the boundary interface of an entity using GUI.

- Assign the EDA Formal Verification Hierarchy value as blackbox.
- Assign the Preserve Hierarchical Boundary assignment with a value of Firm to the entity (Figure 18–6).

**Figure 18–6. Making a Black Box Assignment to an Entity**

The Quartus II software compiler generates the following files and directories:

- VO file: *<design\_name>.vo*.
- Script file: *<design\_name>.fms* used with Formality software.
- A black-box directory: black boxes that contains all the user defined black-box entities in the design which is located in the following directory: *!<project directory>/fv/formality/blackboxes*.

The script file contains the setup constraints used along with the Formality software. The *<entity>.v* file in the black-boxes directory contains the module description of only those entities that are not defined in the formal verification library.

For a sample script containing the setup commands generated by the Quartus II software, refer to “[Tcl Sample Script](#)” on page 18–13.

## Quartus II Scripts for Formality

The Quartus II software generates scripts to use with the Formality software. This section describes the Formality software commands used within the scripts to help customers comparing the implementation and reference netlists. Table 18–2 describes the Formality software commands within Quartus II generated scripts.

**Table 18–2. Formality Software Commands within Quartus II Generated Scripts**

Command	Affect
<code>read_verilog &lt;design_files&gt;</code>	This command reads both the reference and implementation netlists in addition to the appropriate library models.
<code>set_compare_rule &lt;rule&gt;</code>	Adds a name matching rule that Formality software applies to a design before creating compare points.
<code>set_signature_analysis_matching &lt;value&gt;</code>	Use this command to specify whether or not to use signature analysis to match previously compared points.
<code>set_constant &lt;value&gt;</code>	This command allows you to set the logic state of a design object to either 0 or 1.
<code>set_hdlin_altera_generate_naming &lt;value&gt;</code>	This command directs Formality software to apply alter naming conventions for registers.
<code>Set_user_match &lt;mapping_point_name&gt;</code>	Use this command to create pairs of matched points to compare those that Formality software could not match during its matching process.

## Comparing Designs Using the Formality Software

To verify the functional equivalence between post-synthesis and post-place-and-route netlists, use the script file `<file_name>.fms` since it contains references to the macros defined in the Altera formal verification library. Some of the macros used are:

- `_ALTERA_FAMILY_IS_STRATIX_`
- `POST_FIT`
- `FORMALITY`
- `GATES_TO_GATES`

An example on the use of these macros is shown in the `read_verilog` command in the previous section. This script file `<file_name>.fms` is executed from either the GUI or using the following command:

```
%formality -file <file_name>.fms
```

For more information about using the Formality software, refer to the *Formality User Guide*.

The Formality software does not support inferred RAMs in RTL while performing RTL-to-Gates verification. Therefore, you should apply the black box property to RAM that is instantiated by the RTL code.

## Known Issues and Limitations

This section discusses known issues and limitations of the formal verification flow using the DC FPGA, Quartus II, and Formality software:

1. Formal verification of post synthesis verses post-place-and-route netlist does not support latches because latches are implemented using combinational logic with a feedback loop which poses a problem to the Formality software.
2. If an LPM or an Altera megafunction module is inferred and all the ports of the module are not used, then unused ports should be connected to default values in the post-synthesis Verilog HDL netlist.
3. The Quartus II software may optimize away logic feeding a black box, resulting in mismatches on the blackbox inputs. For example, if certain bits of a RAM output are not being used, then the Quartus II software optimizes away the logic feeding the corresponding data inputs.

## Conclusion

Formal verification enables verification of the design during all stages from RTL to place-and-route. As designs become larger, design verification using traditional methods becomes too time consuming. Thus, formal verification easily verifies that any modifications to the netlist in the physical domain have not altered from the Golden netlist. Advanced debugging capabilities within Formality software pinpoints the source of the differences between the Reference and Implementation netlists, enabling the user to easily fix the differences.

## Tcl Sample Script

This section provides an example of the DC FPGA software script to perform synthesis and an example formal verification script generated by the Quartus II software.

### DC FPGA Synthesis Script

The following example script presents the Altera recommended settings in the DC FPGA software for synthesizing the design for the Stratix architecture. The script also generates the Verilog netlist file for formal verification using the Formality software. These tasks are performed in the following five sections of the script:

- Setting up the library
- Default synthesis settings for Altera Stratix
- Analyzing the design files
- Compiling the design
- Generating the Verilog netlist for formal verification

```
# Setup file for Altera Stratix Devices
# Tcl style setup file but will work for
# original DC shell as well
# Need to define the root location of the
# libraries by changing
# the variable $dcfpga_lib_path

The Quartus® II software offers a complete software solution for system designers who design with Altera® FPGA and CPLD devices. The Quartus II Programmer is part of the Quartus II software package that allows you to program Altera CPLD and configuration devices, and configure Altera FPGA devices. This section describes how you can use the Quartus II Programmer to program or configure your device after you successfully compile your design.

This section includes the following chapter:

- [Chapter 19, Quartus II Programmer](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

The Quartus® II software offers a complete software solution for system designers who design with Altera® FPGA and CPLD devices. The Quartus II Programmer is part of the Quartus II software package that allows you to program Altera CPLD and configuration devices, and configure Altera FPGA devices. After your design successfully compiles, you can use the Quartus II Programmer to program or configure your device.

This chapter contains the following sections:

- “Programming Flow”
- “Programming and Configuration Modes” on page 19-4
- “Programmer Overview” on page 19-6
- “Hardware Setup” on page 19-12
- “Device Programming and Configuration” on page 19-14
- “Optional Programming Files” on page 19-18
- “Flash Loaders” on page 19-21
- “Other Programming Tools” on page 19-22
- “Scripting Support” on page 19-22

## Programming Flow

The programming flow begins with design compilation, in which the Quartus II Assembler generates the programming or configuration file, then proceeds with the programming or configuration file conversion for different configuration devices, or optional programming and configuration file creation. The flow ends with the configuration or programming of the FPGA, CPLD, or configuration devices with the programming or configuration file using the Quartus II Programmer.

Figure 19-1 shows the programming file generation flow. This flow covers the types of configuration and programming files that are used by the Quartus II Programmer. Refer to “Optional Programming Files” on page 19-18 for information on other optional programming files.

**Figure 19–1. Programming File Generation Flow**

Table 19–1 shows the programming and configuration file formats supported by Altera FPGAs, CPLDs, configuration devices, enhanced configuration devices, and serial configuration devices.

<b>Table 19–1. Programming and Configuration File Format</b>				
<b>File Format</b>	<b>FPGA</b>	<b>CPLD</b>	<b>Configuration Device and Enhanced Configuration Device</b>	<b>Serial Configuration Device</b>
SOF	✓	—	—	—
POF	—	✓	✓	✓
Jam	✓	✓	✓	—
JBC	✓	✓	✓	—

Figure 19-2 shows the programming flow using the Quartus II Programmer. Refer to “Generating Optional Programming Files” on page 19-20 for detailed information about converting or creating different programming files. Refer to “Device Programming and Configuration” on page 19-14 for information about programming or configuring the device.

**Figure 19-2. Programming Flow**

## Programming and Configuration Modes

The Quartus II Programmer supports the following four programming or configuration modes: JTAG, passive serial, active serial, and in-socket programming.

### JTAG Mode

You can use the Joint Test Action Group (JTAG) mode to configure FPGA devices and program CPLDs, configuration devices, or enhanced configuration devices. The JTAG mode allows multiple FPGAs, CPLDs, and configuration devices connected in a JTAG chain to be configured or programmed at the same time. JTAG programming or configuration uses four JTAG pins: TCK, TDI, TMS, and TDO. The JTAG interface also allows you to perform boundary-scan test using third-party boundary scan tools.

POF files are used for programming CPLDs, and configuration or enhanced configuration devices, while SOF files are used for configuring FPGA devices. Jam and JBC files can be used for both programming and configuration. Serial configuration devices do not support JTAG programming.

For more information about JTAG configuration or programming mode and JTAG pin connection, refer to the *Configuration Handbook*, or the device handbook or data sheet for the respective FPGA, CPLD, or configuration devices.

### Passive Serial Mode

You can use the passive serial (PS) mode to configure Altera FPGAs. PS configuration uses the DCLK, CONF\_DONE, nCONFIG, nSTATUS, and DATA0 configuration pins. Unlike the JTAG scheme, the PS configuration scheme can be used to configure the FPGA with a configuration device or enhanced configuration device, not necessarily through a download cable. If you are using the configuration device or enhanced configuration device to configure the FPGA through PS mode, you can route the configuration signals out to a header so that you can also configure the FPGA through the download cable with the Quartus II Programmer. Configuration through PS mode with a download cable is useful in the design stage. This configuration method allows you to configure your FPGA device directly from the Quartus II Programmer as you make changes to your design for debugging and testing.

PS mode supports configuration of an FPGA chain. SOF files are used for configuration through PS. Every FPGA device in the chain requires a SOF, so the number of SOF files used depends on the number of FPGA devices in the chain.

For more information about PS configuration mode and PS pin connection, refer to the *Configuration Handbook* or the chapter on configuration in the appropriate FPGA device handbook.

### Active Serial Mode

You can use the active serial (AS) mode to program serial configuration devices. After programming completes, the serial configuration device then configures the FPGA. AS programming uses the DATA, DCLK, nCS, and ASDI pins. If the download cable is connected to the nCONFIG and nCE pins of the FPGA, the download cable disables the FPGA's access to the AS interface by holding the nCE pin high and the nCONFIG pin low. Upon completion of the programming, the nCE and nCONFIG pins are released and the FPGA configuration begins.

For more information about programming the serial configuration device, configuring the FPGA with the serial configuration device through AS mode, or the AS pin connection, refer to the *Serial Configuration Data Sheet* in the *Configuration Handbook* or the chapter on configuration in the appropriate FPGA device handbook.

### In-Socket Programming Mode

The in-socket programming mode is used for programming a single device. This programming mode supports programming the MAX<sup>®</sup> 7000 and MAX 3000 CPLD families, configuration devices, enhanced configuration devices, and serial configuration devices. Instead of using a download cable, in-socket programming mode uses the Altera Programming Unit (APU) hardware together with the programming adapter for the corresponding device to program the device. The programming unit with the programming adapter has a socket for the device and the hardware powers the device for programming. In-socket programming is normally used in the production environment to pre-program devices before they are mounted on the printed circuit boards on the assembly line.

Refer to [www.altera.com](http://www.altera.com) or the Quartus II Help for a list of programming adapters available for Altera devices.

Table 19–2 shows the programming and configuration modes supported by Altera devices.

Mode	FPGA	CPLD	Configuration Device and Enhanced Configuration Device	Serial Configuration Device
JTAG	✓	✓	✓	—
PS	✓	—	—	—
AS	—	—	—	✓
In-Socket Programming	—	✓(1)	✓	✓

Note to Table 19–2:

(1) MAX II CPLDs do not support in-socket programming mode.

## Programmer Overview

The Quartus II Programmer graphical user interface (GUI) is a window in which you can add your programming and configuration files, specify the programming options and hardware, and then proceed with the programming or configuration of the device.

To open the **Programmer** window, on the Tools menu, click **Programmer**. Figure 19–3 shows the programmer GUI. The status of each operation, whether programming is successful or not, is reported in the Quartus II message window. Figure 19–4 shows a typical programming message after the programmer has successfully programmed a device.

Figure 19–3. The Programmer Window

Figure 19–4. Status Report in the Message Window

Table 19–3 describes the items available in the programmer window.

<b>Table 19–3. Programmer Window Items (Part 1 of 3)</b>	
<b>Items</b>	<b>Description</b>
<b>Hardware Setup</b>	Opens the <b>Hardware Setup</b> dialog box in the programmer and enables you to perform the following: <ul style="list-style-type: none"> <li>• add and remove hardware items from the <b>Hardware</b> list.</li> <li>• add and remove JTAG servers from the <b>JTAG Servers</b> list.</li> <li>• configure your local JTAG server.</li> <li>• specify a programming hardware or download cable for device programming and configuration.</li> </ul>
<b>Mode</b>	Specifies the programming or configuration mode (either JTAG, In-Socket Programming, Passive Serial, or Active Serial Programming).
<b>Progress</b>	Shows the progress of a specific operation.
<b>Action Buttons</b>	
<b>Start</b>	Starts the operations of the specified programming options.
<b>Stop</b>	Stops all operations in progress.
<b>Auto Detect</b>	Scans the JTAG chain to check for devices in the chain and the chain connection.
<b>Delete</b>	Removes the selected programming or configuration files from the programmer.
<b>Add File</b>	Adds programming or configuration files to the programmer.
<b>Change File</b>	Replaces the selected programming or configuration file with another file.
<b>Save File</b>	Allows you to save the data read out from CPLD or configuration devices using the “examine” process into a POF file.
<b>Add Device</b>	Adds a device into the JTAG device chain in the programmer. If no programming or configuration file is specified, the programmer will bypass this device during programming or configuration. You can also add your user-defined device into the chain.
<b>Up</b>	Moves the selection up to another programming or configuration file or device in the programmer window.
<b>Down</b>	Moves the selection down to another programming or configuration file or device in the programmer window.
<b>File or Device Chain Information</b>	
<b>File</b>	Displays the programming or configuration file name.
<b>Device</b>	The <b>Device</b> column shows: <ul style="list-style-type: none"> <li>• the target device of the file, if you add a programming or configuration file into the programmer.</li> <li>• the devices in the JTAG chain detected by the programmer, if you click <b>Auto Detect</b> in JTAG mode.</li> <li>• the device added to the programmer, if you manually add a device into the programmer.</li> </ul>

**Table 19–3. Programmer Window Items (Part 2 of 3)**

Items	Description
<b>Checksum</b>	<p>The <b>Checksum</b> column shows:</p> <ul style="list-style-type: none"> <li>• the checksum of the file, if you add a programming or configuration file into the programmer.</li> <li>• the checksum for the data read out, if you examine a device.</li> </ul> <p>The checksum is calculated by the Quartus II software. The programmer does not display the checksum for the Jam or JBC files generated for a multi-device JTAG chain.</p>
<b>Usercode</b>	<p>The <b>Usercode</b> column shows:</p> <ul style="list-style-type: none"> <li>• the usercode of the file, if you add a programming or configuration file into the programmer.</li> <li>• the usercode read out from the device, if you examine a device.</li> </ul> <p>You can specify the usercode before design compilation, or use the Auto usercode feature that uses the checksum as the usercode. The programmer does not show the usercode information in PS configuration mode or for the Jam or JBC files generated for a multi-device JTAG chain.</p>
<b>Programming Options</b>	
<b>Enable real-time ISP to allow background programming</b>	Can only be turned on if you are targeting a MAX II device, and is turned off for all other device families. When this option is turned on, you can do the real-time in-system programming (ISP) for the MAX II device. The existing design in the MAX II device functions normally during and after the real-time ISP is completed. The new design starts to function after a power cycle to the device occurs.
<b>Program or Configure</b>	Can be used for programming CPLDs, configuration devices, or configuring FPGA devices.
<b>Verify</b>	Verifies the content of the CPLD and all configuration devices against the respective programming files. This option is not available for FPGAs. Verification fails if the data in the file is different from the data in the device. Stand-alone verification for the CPLD with the programming file used for the programming will fail if the security bit is set when the device is programmed initially.
<b>Blank-Check</b>	Checks whether the CPLD or configuration device is blank or not.
<b>Examine</b>	Reads back the contents of the CPLD or configuration device. You can then save the examined data as a POF file. Examining a CPLD with the security bit set does not produce a usable POF file. MAX 7000S devices require you to add a valid MAX 7000S POF file that targets the same device before you can examine the data back from the device.
<b>Security Bits</b>	Protects the design in the CPLD from being examined. If the security bit is set when the CPLD is programmed, you cannot read the correct data out using the examine process. Security bits cannot be set for the configuration devices or FPGAs.

Items	Description
<b>Erase</b>	Erases the contents of the CPLD and all configuration devices. You can also erase the user flash memory (UFM) of the MAX II CPLD. MAX 7000S devices require you to add a valid MAX 7000S POF file that targets the same device before you can erase the device.
<b>ISP CLAMP</b>	Allows the MAX II or MAX 7000B CPLD's I/O pins to be clamped to certain states during normal programming. ISP CLAMP can only be turned on if certain pins of the device have the ISP Clamp State assignment enabled, or you have added an I/O Pin State (IPS) file in the programmer.
<b>IPS File</b>	Shows the IPS file used for ISP Clamp of the MAX II or MAX 7000B CPLDs. The <b>IPS File</b> column only appears if your programmer window has a MAX II or MAX 7000B POF file. To add in the IPS file, click once on the row of the programming file and on the Edit menu, click <b>Add IPS File</b> .

Table 19–4 shows the programming and configuration options supported by Altera devices.

Option	FPGA	CPLD	Configuration Device and Enhanced Configuration Device	Serial Configuration Device
Program or Configure	✓	✓	✓	✓
Verify	—	✓	✓	✓
Blank-Check	—	✓	✓	✓
Examine	—	✓	✓	✓
Security Bit	—	✓	—	—
Erase	—	✓	✓	✓
ISP Clamp	—	✓(1)	—	—
IPS File (2)	—	✓	—	—
Real-time ISP	—	✓(3)	—	—

**Notes to Table 19–4:**

- (1) Only MAX II and MAX 7000B CPLDs support the ISP Clamp feature.
- (2) IPS file is used for ISP Clamp.
- (3) Only MAX II CPLDs support the real-time ISP feature.

## Tools Menu

More programmer options are available from the Tools menu. On the Tools menu, click **Options** and then click **Programmer**. For descriptions of these options, refer to [Table 19–5](#).

<i>Table 19–5. Programmer Options</i>	
<b>Option</b>	<b>Description</b>
<b>Show checksum without usercode</b>	Determines whether the checksum values displayed in the programmer are calculated with or without JTAG usercodes. This option allows you to have multiple versions of a programming or configuration file with different user codes, but share the same checksum.
<b>Initiate configuration after programming</b>	Specifies that configuration devices configure attached FPGA devices automatically after the programmer completes programming the configuration devices.
<b>Display message when programming finishes</b>	Displays a message when programming or other operation such as examining or blank-checking is complete.
<b>Enable real-time ISP to allow background programming (for MAX II devices)</b>	Can only be turned on if you are targeting a MAX II device. This option is turned off for all other device families. When this option is turned on, you can do the real-time in-system programming (ISP) for the MAX II device. The existing design in the MAX II device functions normally during and after the real-time ISP is completed. The new design starts to function after a power cycle to the device occurs. This option is also available in the programmer window.
<b>Halt on-chip configuration controller</b>	<p>Halts the on-chip auto-configuration controller of the FPGA device for AS configuration, or the configuration device for PS or Fast Passive Parallel (FPP) configuration to allow JTAG configuration through a download cable. If you want to configure your FPGA through JTAG while the FPGA MSEL pins are set to AS mode, you should halt the on-chip configuration controller if any of the following occurs:</p> <ul style="list-style-type: none"> <li>● the active serial configuration device connected to your FPGA is blank</li> <li>● the active serial configuration device is not present</li> <li>● an error occurs during AS configuration prior to JTAG configuration</li> </ul> <p>If the MSEL pins are set to PS or FPP mode, halt the configuration controller of the configuration device if an error occurs during PS or FPP configuration prior to JTAG configuration. The FPGA pulls the nSTATUS pin (which is connected to the OE pin of the configuration device) low to disable the configuration device.</p>
<b>Automatically check the Program/Configure checkbox when adding SOF</b>	Automatically enables the program or configuration operation when adding an SRAM Object File (.sof) to the file list in the programmer window.

## Hardware Setup

The Quartus II Programmer provides the flexibility to choose the download cable or programming hardware. Before you can program or configure your device, you must have the correct hardware setup.

### Hardware Settings

Click **Hardware Setup** to bring up the **Hardware Setup** dialog box. On the **Hardware Settings** tab (Figure 19–5), you can select a download cable or programming hardware available from the **Currently selected hardware** list. If the download cable or programming hardware you require is not displayed, click **Add Hardware** and specify the download cable or programming hardware. Make sure that you have installed the download cable driver before adding the hardware.

 You do not need to manually add the USB-Blaster™ download cable to the list. After installing the driver, simply connect the download cable to the PC before opening the **Hardware Setup** dialog box. The USB-Blaster appears automatically in the list when the dialog box is opened.

*Figure 19–5. Hardware Settings*

More information about programming hardware driver installation is available in the Design Software section under **Support** on the Altera website ([www.altera.com/support](http://www.altera.com/support)).

## JTAG Settings

The JTAG server allows programs such as the Quartus II Programmer to access the JTAG hardware. This application software is installed together with the Quartus II software. You can also access the JTAG download cable or programming hardware connected to a remote computer through the JTAG server of that computer. With the JTAG server, you can control the programming or configuration of devices from a single computer through other computers at remote locations. The JTAG server uses the TCP/IP communications protocol.

Click **Hardware Setup** to bring up the **Hardware Setup** dialog box. On the **JTAG Settings** tab (Figure 19–6), you can add or remove JTAG servers from the list. By default, you have only the local JTAG server (which is on your computer) in the list. By adding a remote JTAG server, you can access the JTAG hardware in that remote computer from your computer. You need the password of the remote JTAG server to add the server to your list. Click **Add Server**, then enter the IP address of that computer in the **Server name** field and the password in the **Server password** field.

Figure 19–6. JTAG Settings

You can also allow remote clients to access the JTAG server on your computer and program or configure devices connected to your computer through the JTAG interface of your computer. Click **Configure Local JTAG Server** to enable the server and then enter the password that the remote clients require to access your JTAG server.

# Device Programming and Configuration

The Quartus II Programmer supports single- or multi-device programming and configuration. This section describes the steps required to program or configure Altera devices, as well as how to bypass Altera and non-Altera devices in a JTAG chain.

## Single Device Programming and Configuration

To program or configure a single device with the Quartus II Programmer, perform the following steps:

1. On the Tools menu, click **Programmer** to open the **Programmer** window.
2. Click **Hardware Setup** and select the programming hardware or download cable. If you are using JTAG mode, you can specify the correct JTAG settings for programming or configuration involving remote JTAG servers. Click **Close**.
3. From the **Mode** list, select the programming or configuration mode.
4. Click **Add File** to add the POF or SOF file to the programmer (you can omit this step if the file is already displayed). To change the file, select it and click **Change File**. To remove the file from the programmer, select it and click **Delete**.

If you are using JTAG, AS, or in-socket programming mode, after the file has been added to the programmer, select the programming or configuration option by turning on the corresponding check box in the programmer.

5. Click **Start**.

## Multi-Device Programming and Configuration

JTAG and PS modes allow you to program or configure a device chain. A JTAG chain can consist of a combination of FPGA, CPLD, and configuration devices that support JTAG mode. A PS chain consists of FPGAs that support PS mode. The steps for programming or configuring a device chain is similar to the steps for programming or configuring a single device. One exception is that in a device chain you must specify all the programming or configuration files for the devices you want to program or configure. JTAG mode allows you to bypass some of the devices in the JTAG chain while programming or configuring the rest of the devices. PS mode does not allow you to bypass devices in the FPGA chain.

### *Bypassing an Altera Device*

If you have the programming or configuration file for the Altera device you want to bypass, in the programmer, turn off all the options in the row for that device before you program or configure other devices. If you do not have the programming or configuration file for that device, click **Add Device** to specify the device.

### *Bypassing a Non-Altera Device*

The JTAG chain of the device you want to program or configure may contain non-Altera devices. To program or configure your Altera device in the JTAG chain, you must bypass those non-Altera devices. The non-Altera devices are not in the list of devices that you can select when you click **Add Device** in the programmer.

To bypass the devices, you must manually define these devices. Click **Add Device** to open the **Select Device** dialog box. Click **New** to define a device. In the **New Device** dialog box (Figure 19–7), enter the name of the device and the JTAG instruction register length of the device. You can find the JTAG instruction register length in the device’s data sheet. You can also specify the JTAG ID code for the device by clicking **Add JTAG ID**. This is optional and you can turn on **Allow none** to set the ID code to all 0s. If you do not specify the JTAG ID code, the default value is all 0s.

**Figure 19–7. New Device Dialog Box**

After defining the device, the device appears in the device list (Figure 19–8). Click **Export** to save the information in a Quartus User-Defined Device (QUD) file. This file saves the information for the user-defined devices that appear under **Device name** in the dialog box and can be used by other Quartus II projects as well. To obtain information on the user-defined devices from the QUD file, click **Import** and the devices are listed under **Device name**.

**Figure 19–8. Select Devices**

Figure 19–9 shows the programmer window for a JTAG chain.

Figure 19–9. Multi-Device JTAG Chain

### Chain Description File

All the information in the Quartus II Programmer, including the programming or configuration mode, programming or configuration files used, device chain information, and the programming options specified can be saved in a chain description file (CDF). You do not have to specify the information each time you program the device chain. Simply open the CDF in the Quartus II software and information appears in the Quartus II Programmer GUI.

### Design Security Key Programming

The Quartus II Programmer supports the generation of encryption key programming files and encrypted configuration files for Altera FPGAs that support the design security feature. You can also use the Quartus II Programmer to program the encryption key into the FPGA.

Refer to *AN 341: Using the Design Security Feature in Stratix II Devices* for more information about using the design security feature with the Quartus II software.

## Optional Programming Files

The Quartus II software is able to generate optional programming or configuration files in various formats to be used with programming tools other than the Quartus II Programmer. In addition, you can convert the FPGA configuration files to programming files for configuration devices.

### Types of Programming and Configuration Files

The Quartus II software generates programming files of various formats for use with different programming tools. Table 19–6 shows the programming and configuration files generated by the Quartus II software.

File Format	Generated by the Quartus II Software	Supported by the Quartus II Programmer	Description
SOF	✓	✓	This configuration data file is used for configuring FPGA devices. The Quartus II Assembler generates this file when you compile your FPGA design.
POF	✓	✓	This programming data file is used for programming CPLDs and configuration devices. The Quartus II Assembler generates the CPLD POF file when you compile your CPLD design. The configuration device POF file is converted from the FPGA SOF file.
Jam	✓	✓	This ASCII-format file is used for configuring or programming one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The Jam file includes both programming algorithm and data. Apart from the Quartus II Programmer, you can use Altera's Jam Standard Test and Programming Language (STAPL) player, the <b>quartus_jli</b> executable, or other third-party programming tools together with the Jam file. The Jam file is also suitable for embedded processor-type programming environments.
JBC	✓	✓	Similar to the Jam file, this binary-format file is used for configuring or programming one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The JBC file includes both the programming algorithm and data, and the size is smaller than the Jam file. In addition to the Quartus II Programmer, you can use Altera's Jam Byte-Code player, the <b>quartus_jli</b> executable, or other third-party programming tools together with the JBC file. The JBC file is also suitable for embedded processor-type programming environments.

**Table 19–6. Types of Programming and Configuration Files (Part 2 of 2)**

File Format	Generated by the Quartus II Software	Supported by the Quartus II Programmer	Description
SVF	✓	—	This ASCII-format file is used for configuring, programming, blank-checking, and verifying one or more FPGAs, CPLDs, and configuration devices in a JTAG chain. The SVF file, which includes programming algorithm and data, is suitable for an automated test equipment (ATE) environment that requires a fixed programming algorithm.
ISC	✓	—	This data file is used with the IEEE 1532 BSDL file for programming a single device that supports IEEE 1532 programming. The Quartus II software supports generating the ISC file for MAX 7000AE, MAX 7000B, and MAX 3000A CPLDs.
Hexout	✓	—	The Hexout file is used for programming FPGA configuration data into enhanced configuration devices or other storage devices. For enhanced configuration devices, use the enhanced configuration device POF to generate the Hexout file. Use the FPGA SOF file to generate the Hexout file for other storage devices (for example, the flash or EEPROM devices). You can use a microcontroller to read back the data from the storage device and configure the FPGA. To program the enhanced configuration device or other storage devices with the Hexout file, you can use other third-party programming tools.
RBF	✓	—	This binary file contains configuration data for one or more FPGAs. You can use Altera's JRunner software to configure your FPGA device with the RBF file. The RBF file is also suitable for embedded processor configuration environments.
TTF	✓	—	This ASCII file contains configuration data for one or more FPGAs. The TTF file is used for embedded processor-type configuration.
RPD	✓	—	This binary file is used for programming serial configuration devices. Use the serial configuration device POF file to generate this file. You can use Altera's SRunner software to program your serial configuration device with the RPD file.
JIC	✓	✓	The JIC file is used for programming serial configuration devices through JTAG with the Quartus II Programmer and Altera FPGAs that support AS configuration mode.

Refer to the Quartus II Help or the *Configuration File Formats* chapter of the *Configuration Handbook* for more information about the programming and configuration file formats.

Refer to *AN 425: Using Command-Line Jam STAPL Solution for Device Programming* for more information about using the Jam and JBC programming files with the Jam STAPL Player, Jam STAPL Byte-Code Player, and the `quartus_jli` command-line executable.

## Generating Optional Programming Files

When you compile your design, the Quartus II Assembler generates the SOF file for an FPGA or a POF file for a CPLD. With the SOF or POF for your design, you can then create other optional programming or configuration files, or convert the SOF to target a particular configuration device.

### *Create Programming Files*

The Quartus II software allows you to create optional Jam, JBC, SVF, or ISC programming or configuration files. In addition, you can create Jam, JBC, and SVF files for a JTAG chain that consists of more than one device.

To create the files, open the Quartus II Programmer, set the programming or configuration mode to JTAG, and then add the programming or configuration files or devices to the programmer. On the File menu, click **Create/Update** and then click **Create JAM, SVF, or ISC File**. Select the file format and name the file accordingly.

For SVF files, you can create an SVF file for programming or verification only. In addition, you can specify whether or not to do the optional blank-check operation with the SVF file.

### *Convert Programming Files*

To store the FPGA data into configuration devices, you can convert the SOF data to another format and program the configuration device. The Quartus II software supports converting the data into POF, Hexout, RBF, TTF, RPD, or JIC format.

For more information about converting programming files with the Quartus II software, refer to the *Configuration File Formats* chapter of the *Configuration Handbook*.

### *Generating Optional Programming or Configuration Files During Compilation*

The Quartus II software can generate optional programming or configuration files automatically when you compile your design. To select the format of the optional programming or configuration files to be generated during compilation, on the Assignments menu, click **Settings**. Under **Device**, click **Device and Pin Options**.

You can select the configuration device from the **Configuration** tab for the configuration device POF generation. For other optional programming and configuration file generation, you can select the file format under the **Programming Files** tab.

## Flash Loaders

Serial configuration devices and the common flash interface (CFI) flash devices do not support JTAG interface and cannot be programmed directly through the normal JTAG programming. Flash loaders allow the programming of the serial configuration device and the CFI flash from the Quartus II Programmer through JTAG.

### Parallel Flash Loader

The parallel flash loader (PFL) performs two functions:

- Allows the programming of the CFI flash through the JTAG interface
- Acts as the configuration controller that reads the configuration data from the CFI flash and configures the FPGA

To program the CFI flash, the PFL uses the MAX II device as a bridge between the JTAG interface of the Quartus II Programmer and the CFI of the CFI flash device. You can program FPGA configuration data and user data into the flash with a flash POF generated by the Quartus II software. After the flash is programmed with the FPGA configuration data, the PFL is then used to read the configuration data back from the CFI flash to configure the FPGA.

Refer to *AN 386: Using the MAX II Parallel Flash Loader with the Quartus II Software* for more information about PFL.

### Serial Flash Loader

The serial flash loader (SFL) allows programming of the serial configuration devices through JTAG. The SFL uses the FPGA device that supports AS configuration mode as a bridge between the active serial memory interface (ASMI) of the serial configuration device and the JTAG

interface of the programmer. The Quartus II Programmer uses the JIC file converted from the FPGA SOF file to program the serial configuration device through JTAG.

Refer to *AN 370: Using the Serial Flash Loader with the Quartus II Software* for more information about SFL.

## Other Programming Tools

This section covers other programming tools that are related to the Quartus II Programmer and can be used for programming or debugging programming problems.

### Quartus II Stand-Alone Programmer

If you do not have the full version of the Quartus II software, Altera offers the free Quartus II Stand-Alone Programmer. This stand-alone programmer has the full function of the normal Quartus II Programmer, and enables you to create or convert programming files from the SOF or POF of your design. You can download the Quartus II Stand-Alone Programmer from the **Download Center** page found through the **Support** page on the Altera website at [www.altera.com](http://www.altera.com).

### jtagconfig Debugging Tool

The **jtagconfig** command-line utility is included with the Quartus II software. You can use this utility (which is similar to the auto detect operation in the Quartus II Programmer) to check the devices in a JTAG chain and the user-defined devices.

For more information about the **jtagconfig** utility, type one of the following commands at the command prompt:

```
jtagconfig -h ←  
jtagconfig --help ←
```

## Scripting Support

Apart from the Quartus II Programmer GUI, you can perform programming with the Quartus II command-line programmer (**quartus\_pgm**). This **quartus\_pgm** command-line programmer comes with the Quartus II Programmer. You can run this programmer separately from the Quartus II software. You can also run the procedures for the programmer in a Tcl script. The programmer accepts the POF, SOF, and JIC programming or configuration files. You can also use the CDF.

For more information about the command-line syntax, type one of the following commands at the command prompt:

```
quartus_pgm -h ↵
quartus_pgm --help ↵
```

For more information about a specific programmer option or topic, type the following command at the command prompt:

```
quartus_pgm --help=<option|topic> ↵
```

The following is an example of a command that programs a device:

```
quartus_pgm -c byteblasterII -m jtag -o bpv;design.pof ↵
```

where:

- c byteblasterII specifies the ByteBlaster II download cable
- m jtag specifies the JTAG programming mode
- o bpv represents the blank-check, program, and verify operations
- design.pof represents the POF file used for the programming

The programmer automatically executes the erase operation before programming the device.

For detailed information about scripting command options, you can also refer to the Quartus II Command-Line and Tcl API Help browser. To run the Help browser, type the following command at the command prompt:

```
quartus_sh --qhelp ↵
```

The *Scripting Reference Manual* includes the same information in PDF format.

For more information about Tcl scripting, refer to the *Tcl Scripting* chapter in volume 2 of the *Quartus II Handbook*. Refer to the *Quartus II Settings File Reference Manual* for information on all settings and constraints in the Quartus II software. Refer to the *Command-Line Scripting* chapter in volume 2 of the *Quartus II Handbook* for more information about command-line scripting.

## Conclusion

The Quartus II Programmer offers you a wide variety of options to program and configure your Altera devices. With the Quartus II Programmer, the Quartus II software provides you with a complete solution for your FPGA or CPLD design prototyping, which can even be performed in the production environment.

## Section I. SOPC Builder Features

### Chapter 1. Introduction to SOPC Builder

Overview .....	1-1
Architecture of SOPC Builder Systems .....	1-2
SOPC Builder Components .....	1-2
Example System .....	1-3
Custom Components .....	1-4
System Interconnect Fabric .....	1-5
Functions of SOPC Builder .....	1-5
Defining and Generating the System Hardware .....	1-5
Creating a Memory Map for Software Development .....	1-6
Creating a Simulation Model and Test Bench .....	1-6
Getting Started .....	1-7
Referenced Documents .....	1-7
Document Revision History .....	1-8

### Chapter 2. System Interconnect Fabric for Memory-Mapped Interfaces

Introduction .....	2-1
High-Level Description .....	2-1
Fundamentals of Implementation .....	2-4
Functions of System Interconnect Fabric .....	2-4
Address Decoding .....	2-5
Datapath Multiplexing .....	2-6
Wait-State Insertion .....	2-7
Pipeline Read Transfers .....	2-8
Native Address Alignment and Dynamic Bus Sizing .....	2-9
Dynamic Bus Sizing .....	2-9
Wider Master .....	2-10
Narrower Master .....	2-10
Native Address Alignment .....	2-11
Arbitration for Multimaster Systems .....	2-12

Traditional Shared Bus Architectures .....	2-12
Slave-Side Arbitration .....	2-13
Arbiter Details .....	2-14
Arbitration Rules .....	2-15
Setting Arbitration Parameters in SOPC Builder .....	2-15
Fairness-Based Shares .....	2-16
Round-Robin Scheduling .....	2-17
Burst Transfers .....	2-17
Minimum Share Value .....	2-17
Burst Management .....	2-18
Clock Domain Crossing .....	2-19
Description of Clock Domain-Crossing Logic .....	2-19
Location of Clock Domain Crossing Logic .....	2-21
Duration of Transfers Crossing Clock Domains .....	2-22
Implementing Multiple Clock Domains in SOPC Builder .....	2-22
Component Overview .....	2-23
Functional Description .....	2-23
Interfaces .....	2-24
Clock Domain Crossing Logic and FIFOs .....	2-24
Burst Support .....	2-25
Example System with Avalon-MM Clock-Crossing Bridges .....	2-26
Instantiating the Avalon-MM Clock-Crossing Bridge in SOPC Builder .....	2-28
Interrupts .....	2-29
Software Priority .....	2-29
Hardware Priority .....	2-30
Assigning IRQs in SOPC Builder .....	2-30
Reset Distribution .....	2-31
Referenced Documents .....	2-31
Document Revision History .....	2-32

### Chapter 3. System Interconnect Fabric for Streaming Interfaces

Introduction .....	3-1
High-Level Description .....	3-1
Avalon Streaming and Avalon Memory-Mapped Interfaces .....	3-2
Adapters .....	3-3
Data Format Adapter .....	3-4
Timing Adapter .....	3-4
Channel Adapter .....	3-5
Multiplexer Examples .....	3-5
Example to Double Clock Frequency .....	3-5
Example to Double Data Width and Maintain Frequency .....	3-6
Example to Boost the Frequency .....	3-6
Referenced Documents .....	3-7
Document Revision History .....	3-7

### Chapter 4. SOPC Builder Components

Introduction .....	4-1
--------------------	-----

New Component Structure in v7.1 of the Quartus II Software .....	4-1
Component Providers .....	4-2
Component Hardware Structure .....	4-2
Components That Include Logic Inside the System Module .....	4-3
Components That Interface to Logic Outside the System Module .....	4-4
List of Available Components in SOPC Builder .....	4-4
Tcl Components .....	4-5
Component Description File (_hw.tcl) .....	4-5
Component File Organization .....	4-5
Referenced Document .....	4-6
Document Revision History .....	4-6
<b>Chapter 5. Component Editor</b>	
Introduction .....	5-1
Component Hardware Structure .....	5-2
Starting the Component Editor .....	5-2
HDL Files Tab .....	5-2
Signals Tab .....	5-3
Naming Signals for Automatic Type and Interface Recognition .....	5-4
Templates for Interfaces to External Logic .....	5-5
Interfaces Tab .....	5-6
Component Wizard Tab .....	5-6
Identifying Information .....	5-6
Parameters .....	5-7
Saving a Component .....	5-7
Editing a Component .....	5-8
Referenced Documents .....	5-8
Document Revision History .....	5-9
<b>Chapter 6. Building a Component Interface with Tcl Scripting Commands</b>	
Organization of a Component Tcl File .....	6-2
Set and Add Commands .....	6-3
Module Properties .....	6-4
Clock Interface .....	6-4
Avalon-MM Master Interface .....	6-5
Avalon-MM Slave Interface .....	6-5
Avalon-ST Source Interface .....	6-6
Avalon-ST Sink Interface .....	6-7
Avalon-MM Tristate Interface .....	6-7
Nios II Custom Instruction Interface .....	6-8
Interrupt Interface .....	6-9
Conduit Interface .....	6-10
Document Revision History .....	6-10
<b>Chapter 7. Archiving SOPC Builder Projects</b>	
Introduction .....	7-1
Scope .....	7-1

Required Files .....	7-2
SOPC Builder Design Files .....	7-3
Nios II Application Software Project Files .....	7-3
Nios II System Library Project .....	7-4
File Write Permissions .....	7-4
Referenced Documents .....	7-4
Document Revision History .....	7-5

## Section II. Building Systems with SOPC Builder

### Chapter 8. Building Memory Subsystems Using SOPC Builder

Introduction .....	8-1
Example Design .....	8-2
Example Design Structure .....	8-2
Example Design Starting Point .....	8-4
Hardware and Software Requirements .....	8-5
Design Flow .....	8-5
Component-Level Design in SOPC Builder .....	8-6
SOPC Builder System-Level Design .....	8-6
Simulation .....	8-7
Quartus II Project-Level Design .....	8-7
Board-Level Design .....	8-7
Simulation Considerations .....	8-7
Generic Memory Models .....	8-7
Vendor-Specific Memory Models .....	8-8
On-Chip RAM and ROM .....	8-8
Component-Level Design for On-Chip Memory .....	8-8
Memory Type .....	8-8
Size .....	8-9
Read Latency .....	8-9
Non-Default Memory Initialization .....	8-9
Enable In-System Memory Content Editor Feature .....	8-10
SOPC Builder System-Level Design for On-Chip Memory .....	8-10
Simulation for On-Chip Memory .....	8-10
Quartus II Project-Level Design for On-Chip Memory .....	8-10
Board-Level Design for On-Chip Memory .....	8-11
Example Design with On-Chip Memory .....	8-11
EPCS Serial Configuration Device .....	8-12
Component-Level Design for an EPCS Device .....	8-12
SOPC Builder System-Level Design for an EPCS Device .....	8-12
Simulation for an EPCS Device .....	8-13

## Chapter 9. Developing Components for SOPC Builder

Introduction .....	9-1
SOPC Builder Components and the Component Editor .....	9-1
Prerequisites .....	9-2
Hardware and Software Requirements .....	9-2
Component Development Flow .....	9-3
Typical Design Steps .....	9-3
Hardware Design .....	9-4
Software Design .....	9-6
Verifying the Component .....	9-8
Unit Verification .....	9-8
System-Level Verification .....	9-8
Design Example: Checksum Master .....	9-9
Install the Design Files .....	9-9
Review the Example Design Specifications .....	9-10
Checksum Design Files .....	9-11
Master Task Logic .....	9-11

Register File .....	9–12
Avalon-MM Clock Interface .....	9–12
Avalon-MM Master Interface .....	9–13
Avalon-MM Slave Interface .....	9–13
Software API .....	9–14
Create an SOPC Builder component .....	9–14
Open the Quartus II Project and Start the Component Editor .....	9–14
HDL Files Tab .....	9–15
Signals Tab .....	9–15
Interfaces Tab .....	9–18
Component Wizard Tab .....	9–23
Save the Component .....	9–23
Instantiate the Component in Hardware .....	9–24
Add the checksum Master Component to the SOPC Builder System .....	9–24
Compile the Hardware Design and Download to the Target Board .....	9–25
Exercise the Hardware Using Nios II Software .....	9–25
Start the Nios II IDE and Create a New IDE Project .....	9–26
Compile the Software Project and Run on the Target Board .....	9–28
Sharing Components .....	9–29
Referenced Documents .....	9–31
Document Revision History .....	9–31

## Section III. Interconnect Components

### Chapter 10. Avalon Memory-Mapped Bridges

Introduction to Bridges .....	10–1
Structure of a Bridge .....	10–1
Reasons for Using a Bridge .....	10–3
Address Mapping for Systems with Avalon-MM Bridges .....	10–7
Tools for Visualizing the Address Map .....	10–8
Differences between Avalon-MM Bridges and Avalon-MM Tristate Bridges .....	10–8
Avalon-MM Pipeline Bridge .....	10–9
Component Overview .....	10–9
Functional Description .....	10–10
The following sections describe the component’s hardware functionality. ....	10–11
Interfaces .....	10–11
Pipeline Stages and Effects on Latency .....	10–11
Burst Support .....	10–12
Example System with Avalon-MM Pipeline Bridges .....	10–12
Instantiating the Avalon-MM Pipeline Bridge in SOPC Builder .....	10–13
Device Support .....	10–14
Installation and Licensing .....	10–14
Hardware Simulation Considerations .....	10–15
Software Programming Model .....	10–15
Referenced Documents .....	10–15

Document Revision History ..... 10–15

**Chapter 11. Avalon Streaming Interconnect Components**

Introduction to Interconnect Components ..... 11–1

    Interconnect Component Usage ..... 11–1

    Address Mapping ..... 11–3

Timing Adapter ..... 11–3

    Resource Usage and Performance ..... 11–4

Instantiating the Timing Adapter in SOPC Builder ..... 11–5

    Input Interface Parameters ..... 11–5

    Output Interface Parameters ..... 11–5

    Common to Input and Output Interfaces ..... 11–5

        Channel Signal Width (Bits) ..... 11–6

        Max Channel ..... 11–6

        Bits Per Symbol ..... 11–6

        Symbols Per Beat ..... 11–6

        Include Packet Support ..... 11–6

        Error Signal Width (Bits) ..... 11–6

Data Format Adapter ..... 11–6

    Resource Usage and Performance ..... 11–7

    Instantiating the Data Format Adapter in SOPC Builder ..... 11–9

    Input Interface Parameters ..... 11–9

        Data Symbols Per Beat ..... 11–9

    Output Interface Parameters ..... 11–9

        Data Symbols Per Beat ..... 11–9

    Common to Input and Output ..... 11–9

        Support Backpressure with the Ready Signal ..... 11–9

        Data Bits Per Symbol ..... 11–9

        Channel Signal Width (Bits) ..... 11–9

        Max Channel ..... 11–9

        Include Packet Support ..... 11–10

        Error Signal Width (Bits) ..... 11–10

Channel Adapter ..... 11–10

    Resource Usage and Performance ..... 11–10

    Instantiating the Channel Adapter in SOPC Builder ..... 11–11

    Input Interface Parameters ..... 11–11

        Channel Signal Width (Bits) ..... 11–11

        Max Channel ..... 11–11

    Output Interface Parameters ..... 11–11

        Channel Signal Width (Bits) ..... 11–11

        Max Channel ..... 11–11

    Common to Input and Output Interfaces ..... 11–11

        Data Bits Per Symbol ..... 11–11

        Symbols Per Beat ..... 11–12

        Include Packet Support ..... 11–12

        Error Signal Width (Bits) ..... 11–12

Device Support ..... 11–12

Installation and Licensing .....	11-13
Hardware Simulation Considerations .....	11-13
Software Programming Model .....	11-13
Referenced Documents .....	11-13
Document Revision History .....	11-13

# Chapter Revision Dates

The chapters in this book, *Quartus II Handbook, Volume 4*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

- Chapter 1. Introduction to SOPC Builder  
Revised: *October 2007*  
Part number: *QII54001-7.2.0*
  
- Chapter 2. System Interconnect Fabric for Memory-Mapped Interfaces  
Revised: *October 2007*  
Part number: *QII54003-7.2.0*
  
- Chapter 3. System Interconnect Fabric for Streaming Interfaces  
Revised: *October 2007*  
Part number: *QII54019-7.2.0*
  
- Chapter 4. SOPC Builder Components  
Revised: *October 2007*  
Part number: *QII54004-7.2.0*
  
- Chapter 5. Component Editor  
Revised: *October 2007*  
Part number: *QII54005-7.2.0*
  
- Chapter 6. Building a Component Interface with Tcl Scripting Commands  
Revised: *October 2007*  
Part number: *QII54022-7.2.0*
  
- Chapter 7. Archiving SOPC Builder Projects  
Revised: *October 2007*  
Part number: *QII54017-7.2.0*
  
- Chapter 8. Building Memory Subsystems Using SOPC Builder  
Revised: *October 2007*  
Part number: *QII54006-7.2.0*
  
- Chapter 9. Developing Components for SOPC Builder  
Revised: *October 2007*  
Part number: *QII54007-7.2.1*

Chapter 10. Avalon Memory-Mapped Bridges

Revised: *October 2007*

Part number: *QII54020-7.2.0*

Chapter 11. Avalon Streaming Interconnect Components

Revised: *October 2007*

Part number: *QII54021-7.2.0*

# About this Handbook

This handbook provides comprehensive information about the Altera® SOPC Builder tool.

## How to Contact Altera

For the most up-to-date information about Altera products, refer to the following table.

Information Type	USA and Canada
Technical support	<a href="http://www.altera.com/mysupport/">www.altera.com/mysupport/</a>
Technical training	<a href="http://www.altera.com/training/custrain@altera.com">www.altera.com/training/custrain@altera.com</a>
Product literature	<a href="http://www.altera.com/literature">www.altera.com/literature</a>
Altera literature services	<a href="mailto:literature@altera.com">literature@altera.com</a>
FTP site	<a href="ftp.altera.com">ftp.altera.com</a>

## Typographic Conventions

This document uses the typographic conventions shown below.

Visual Cue	Meaning
<b>Bold Type with Initial Capital Letters</b>	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: <b>Save As</b> dialog box.
<b>bold type</b>	External timing parameters, directory names, project names, disk drive names, filenames, filename extensions, and software utility names are shown in bold type. Examples: <b>f<sub>MAX</sub></b> , <b>lqdesigns</b> directory, <b>d:</b> drive, <b>chiptrip.gdf</b> file.
<i>Italic Type with Initial Capital Letters</i>	Document titles are shown in italic type with initial capital letters. Example: <i>AN 75: High-Speed Board Design</i> .
<i>Italic type</i>	Internal timing parameters and variables are shown in italic type. Examples: <i>t<sub>PIA</sub></i> , <i>n + 1</i> .  Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: <file name>, <project name>.pdf file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
"Subheading Title"	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: "Typographic Conventions."

Visual Cue	Meaning
Courier type	<p>Signal and port names are shown in lowercase Courier type. Examples: <code>data1</code>, <code>tdi</code>, <code>input</code>. Active-low signals are denoted by suffix <code>n</code>, e.g., <code>resetn</code>.</p> <p>Anything that must be typed exactly as it appears is shown in Courier type. For example: <code>c:\qdesigns\tutorial\chiptrip.gdf</code>. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword <code>SUBDESIGN</code>), as well as logic function names (e.g., <code>TRI</code>) are shown in Courier.</p>
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
	Bullets are used in a list of items when the sequence of the items is not important.
	The checkmark indicates a procedure that consists of one step only.
	The hand points to information that requires special attention.
	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
	A warning calls attention to a condition or possible situation that can cause injury to the user.
	The angled arrow indicates you should press the Enter key.
	The feet direct you to more information on a particular topic.

---

Section I of this volume introduces the SOPC Builder system integration tool, and describes the main features of the SOPC Builder tool. Chapters in this section serve to answer the following questions:

- What is SOPC Builder?
- What features does SOPC Builder provide?

This section includes the following chapters:

- Chapter 1, Introduction to SOPC Builder
- Chapter 2, System Interconnect Fabric for Memory-Mapped Interfaces
- Chapter 3, System Interconnect Fabric for Streaming Interfaces
- Chapter 4, SOPC Builder Components
- Chapter 5, Component Editor
- Chapter 6, Building a Component Interface with Tcl Scripting Commands
- Chapter 7, Archiving SOPC Builder Projects

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Overview

SOPC Builder is a powerful system development tool for creating systems including processors, peripherals, and memories. SOPC Builder enables you to define and generate a complete system-on-a-programmable-chip (SOPC) in much less time than using traditional, manual integration methods. SOPC Builder is included in the Quartus® II software.

Many designers already know SOPC Builder as the tool for creating systems based on the Nios® II processor. However, SOPC Builder is more than a Nios II system builder; it is a general-purpose tool for creating systems that may or may not contain a processor.

SOPC Builder automates the task of integrating hardware components into a larger system. Using traditional system-on-chip (SOC) design methods, you must manually write top-level HDL files that wire together the pieces of the system. Using SOPC Builder, you specify the system components in a GUI, and SOPC Builder generates the interconnect logic automatically. SOPC Builder outputs HDL files that define all components of the system, and a top-level HDL design file that connects all the components together. SOPC Builder generates both Verilog HDL and VHDL equally, and does not favor one over the other. This chapter includes the following sections:

- [“Architecture of SOPC Builder Systems” on page 1-2](#)
- [“Functions of SOPC Builder” on page 1-5](#)
- [“Getting Started” on page 1-7](#)

In addition to its role as a system generation tool, SOPC Builder provides features to ease writing software and to accelerate system simulation.

This chapter introduces you to the architectural structure of systems built with SOPC Builder, and describes the primary functions of SOPC Builder.

## Architecture of SOPC Builder Systems

This section describes the fundamental architecture of an SOPC Builder system.

An SOPC Builder component is a design module that SOPC Builder recognizes and can automatically integrate into a system. You can also define and add custom components. SOPC Builder connects multiple components together to create a top-level HDL file called the system module. SOPC Builder generates system interconnect fabric that contains logic to manage the connectivity of all components in the system.

### SOPC Builder Components

SOPC Builder components are the building blocks for creating an SOPC Builder system. SOPC Builder components use Avalon® interfaces for the physical connection of components, and you can use SOPC Builder to connect any logical device (either on-chip or off-chip) that has an Avalon interface. There are two different Avalon interfaces:

- The Avalon® Memory-Mapped (Avalon-MM) interface uses an address-mapped read/write protocol that enables flexible topologies for connecting master components to read and/or write any slave components.
- The Avalon Streaming (Avalon-ST) interface is a high-speed, unidirectional, system interconnect that enables point-to-point connections between streaming components that send and receive data using source and sink ports.

SOPC builder components can use either Avalon-MM or Avalon-ST interfaces or both.

For details on the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification* chapter in volume 4 of the *Quartus II Handbook*. For details about the Avalon-ST interface, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook*. For details about the Avalon-ST interface protocol, refer to *Avalon Streaming Interface Specification*. All are available at [www.altera.com](http://www.altera.com).

### Example System

Figure 1-1 shows an FPGA design including an SOPC Builder system module and custom logic modules. You can integrate custom logic inside or outside the system module. In this example, the custom component inside the system module is an SOPC Builder component that communicates with other modules through an Avalon-MM master interface. The custom logic outside of the system module is connected to the system module through a PIO interface. The system module includes two SOPC Builder components with Avalon-ST source and sink interfaces. The system interconnect fabric connects all of the SOPC Builder components using the Avalon-MM or Avalon-ST system interconnect as appropriate.

**Figure 1-1. Example of an FPGA with a System Module Generated by SOPC Builder**

A component can be a logical device that is entirely contained within the system module, such as the processor component shown in [Figure 1-1](#). Alternately, a component can act as an interface to an off-chip device, such as the DDR2 interface component in [Figure 1-1](#). In addition to the Avalon interface, a component can have other signals that connect to logic outside the system module. Non-Avalon signals can provide a special-purpose interface to the system module, such as the PIO in [Figure 1-1](#). A component can be instantiated more than once per design.

Altera and third-party developers provide ready-to-use SOPC Builder components, including:

- Microprocessors, such as the Nios II processor
- Microcontroller peripherals, such as a scatter-gather DMA controller
- Timers
- Serial communication interfaces, such as a UART and a serial peripheral interface (SPI)
- General purpose I/O
- Digital signal processing (DSP) functions
- Communications peripherals, such as a 10/100/1000 Ethernet MAC
- Interfaces to off-chip devices, such as:
  - Buses and bridges
  - Application-specific standard products (ASSP)
  - Application-specific integrated circuits (ASIC)
  - Processors

### *Custom Components*

SOPC Builder provides an easy method for you to develop and connect your own components. Your components can use either the Avalon-MM or Avalon-ST interfaces, or both. With the Avalon-MM interface, custom logic need only adhere to a simple interface based on address, data, read-enable, and write-enable signals. With the Avalon-ST interface, custom logic follows the configurable Avalon-ST interface protocol.

You use the following design flow to integrate custom logic into an SOPC Builder system:

1. Define the interface to the custom component.
2. Write HDL files describing the component in either Verilog HDL or VHDL.
3. Use the SOPC Builder component editor wizard to specify the interface and optionally package your HDL files into an SOPC Builder component.

4. Instantiate your component in the same manner as other SOPC Builder components.

Once you have created an SOPC Builder component, you can reuse the component in other SOPC Builder systems, and share the component with other design teams.

For instructions on developing a custom SOPC Builder component, refer to the *Developing SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*. For complete details about the file structure of a component, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*. For details about the SOPC Builder component editor, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

### System Interconnect Fabric

The system interconnect fabric connects the components in SOPC Builder-generated systems. For Avalon-MM components, the system interconnect fabric is the collection of signals and logic that connects master and slave components, including address decoding, data-path multiplexing, wait-state generation, arbitration, interrupt controller, and data-width matching. For Avalon-ST components, the system interconnect fabric creates point-to-point connections between streaming components that send and receive data using source and sink ports.

For further details, refer to the *System Interconnect Fabric for Memory-Mapped Interfaces* and *System Interconnect Fabric for Streaming Interfaces* chapters in volume 4 of the *Quartus II Handbook*.

## Functions of SOPC Builder

This section describes the fundamental functions of SOPC Builder.

### Defining and Generating the System Hardware

The purpose of SOPC Builder is to allow you to easily define the structure of a hardware system, and then generate the system. The GUI allows you to add components to a system, configure the components, and specify how they connect together.

After you add all components and system parameters, SOPC Builder generates the system interconnect fabric and output HDL files. During system generation, SOPC Builder outputs the following items:

- An HDL file for the top-level system module and for each component in the system
- A Block Symbol File (.bsf) representation of the top-level system module for use in Quartus II Block Diagram Files (.bdf)
- Software files for embedded software development, such as a memory-map header file and component driver
- (Optional) Testbench for the system module and ModelSim® simulation project files

After you generate the system module, you can compile it with the Quartus II software, or you can instantiate it in a larger FPGA design.

### **Creating a Memory Map for Software Development**

When connected to the Nios II processor, SOPC Builder generates a header file that defines the address of each Avalon-MM slave component. In addition, each slave component can provide software drivers and other software functions and libraries for the processor.

How you write software for the system depends heavily on the nature of the processor in the system. For example, Nios II processor systems use Nios II processor-specific software development tools. These tools are separate from SOPC Builder, but they do use the output of SOPC Builder as the foundation for software development.

### **Creating a Simulation Model and Test Bench**

You can simulate your custom systems with minimal effort immediately after generating the system with SOPC Builder. During system generation, SOPC Builder optionally outputs a push-button simulation environment that eases the system simulation effort. SOPC Builder generates both a simulation model and a testbench for the entire system. The testbench includes the following functionality:

- Instantiates the system module
- Drives all clocks and resets appropriately
- Optionally instantiates simulation models for off-chip devices

## Getting Started

One of the easiest ways to get started using SOPC Builder is to read the *Nios II Hardware Development Tutorial* which guides you step by step in building a microprocessor system, including CPU, memory, and peripherals. This tutorial and other SOPC Builder example designs are included in the Nios II Embedded Design Suite (EDS). You can download this design suite for free from the Altera Download Center at [www.altera.com/download](http://www.altera.com/download).

## Document Revision History

Table 1–1 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007, v7.2.0	<ul style="list-style-type: none"> <li>Updated with new 7.2 functionality and terminology. Deleted unneeded description of SOPC Builder Ready Components.</li> </ul>	—
May 2007, v7.1.0	<ul style="list-style-type: none"> <li>Updated Avalon terminology because of changes to Avalon technologies. Changed old “Avalon switch fabric” term to “system interconnect fabric.” Changed old “Avalon interface” terms to “Avalon Memory-Mapped interface.”</li> <li>Added new information on Avalon Streaming (Avalon-ST) interface.</li> <li>Revised system module block diagram</li> <li>Added Referenced Documents section.</li> </ul>	This chapter was revised to introduce the Avalon streaming interface in addition to the Avalon Memory-Mapped interface. The block diagram was made more comprehensive.
March 2007, v7.0.0	No change from previous release	—
November 2007, v6.1.0	No change from previous release.	—
May 2006, v6.0.0	No change from previous release.	—
October 2005, v5.1.0	No change from previous release.	—
May 2005, v5.0.0	No change from previous release.	—
February 2005, v1.0	Initial release.	—

### Introduction

System interconnect fabric for memory-mapped interfaces is a high-bandwidth interconnect structure for connecting components that use the Avalon® Memory-Mapped (Avalon-MM) interface. System interconnect fabric consumes minimal logic resources and provides greater flexibility than a typical shared system bus. This is a cross-connect fabric and not a tristated or time-sliced shared medium. This chapter describes the functions of system interconnect fabric for memory-mapped interfaces and the implementation of those functions.

### High-Level Description

System interconnect fabric is the collection of interconnect and logic resources that connects Avalon-MM master and slave ports on components in a system. SOPC Builder generates system interconnect fabric to match the needs of the specific components in a system. System interconnect fabric encapsulates the connection details of a system. It guarantees that signals travel correctly between master and slave ports, as long as the ports adhere to the rules of the Avalon Memory-Mapped interface specification. This chapter provides information on the following topics:

- “Address Decoding” on page 2-5
- “Datapath Multiplexing” on page 2-6
- “Wait-State Insertion” on page 2-7
- “Pipeline Read Transfers” on page 2-8
- “Native Address Alignment and Dynamic Bus Sizing” on page 2-9
- “Arbitration for Multimaster Systems” on page 2-12
- “Burst Management” on page 2-18
- “Clock Domain Crossing” on page 2-19
- “Interrupts” on page 2-29
- “Reset Distribution” on page 2-31

For details about the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification*

System interconnect fabric for memory-mapped interfaces supports:

- Any number of master and slave components. The master-to-slave relationship can be one-to-one, one-to-many, many-to-one, or many-to-many.
- On-chip components

- Interfaces to off-chip devices
- Master and slave ports of differing data widths
- Big-endian or little-endian components
- Components operating in different clock domains
- Components using multiple Avalon-MM ports

Figure 2-1 shows a simplified diagram of the system interconnect fabric in an example memory-mapped system with multiple masters.

All figures in this chapter are simplified to show only the particular function being discussed. In a complete system, the system interconnect fabric might alter the address, data, and control paths beyond what is shown in any one particular figure.

Figure 2-1. System Interconnect Fabric—Example System

SOPC Builder supports components with multiple Avalon-MM ports, such as the processor component shown in Figure 2-1. Because SOPC Builder can create system interconnect fabric to connect components with multiple ports, you can create complex interfaces that provide more functionality than a single Avalon-MM port. For example, you can create a component with two different Avalon-MM slaves, each with an associated interrupt interface.

System interconnect fabric can connect any topology of component connections, as long as each port conforms to the Avalon interface specification. It can, for example, connect a system comprised of only two components with unidirectional dataflow between them. Avalon-MM interfaces are suitable for random addressable transactions, such as to memories or embedded peripherals. Avalon-ST interfaces are suitable for dataflow interconnection, as found in packet processing or DSP pipelines.

For more information, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook* and the *Avalon Streaming Interface Specification*.

Generating system interconnect fabric is SOPC Builder's primary purpose. SOPC Builder can be used to manage and edit your design. Because SOPC Builder automatically generates system interconnect fabric, you may not be required to interact directly with it or the HDL that describes it; however, a basic understanding of how it works can help you optimize your components and systems. For example, knowledge of the arbitration mechanism can help designers of multimaster systems minimize the impact of arbitration on the system throughput.

## Fundamentals of Implementation

System interconnect fabric for memory-mapped interfaces implements a switched interconnect structure that provides concurrent paths between master and slave ports. System interconnect fabric consists of synchronous logic and routing resources inside the FPGA.

For each port interface on components, system interconnect fabric manages Avalon-MM transfers, interacting with and responding to signals on the connected component. The signals that appear on the master port and corresponding slave port of a master-slave pair can be different. In the path between master and slave ports, the system interconnect fabric might introduce registers for timing synchronization, finite state machines for event sequencing, or nothing at all, depending on the services required by the specific ports.

## Functions of System Interconnect Fabric

System interconnect fabric logic provides the following functions:

- [“Address Decoding” on page 2-5](#)
- [“Datapath Multiplexing” on page 2-6](#)
- [“Wait-State Insertion” on page 2-7](#)
- [“Pipeline Read Transfers” on page 2-8](#)
- [“Native Address Alignment and Dynamic Bus Sizing” on page 2-9](#)
- [“Arbitration for Multimaster Systems” on page 2-12](#)

- “Burst Management” on page 2-18
- “Clock Domain Crossing” on page 2-19
- “Interrupts” on page 2-29
- “Reset Distribution” on page 2-31

The behavior of these functions in a specific SOPC Builder system depends on the design of the components in the system and the settings made in SOPC Builder. The remaining sections of this chapter describe how SOPC Builder implements each function.

## Address Decoding

Address decoding logic in the system interconnect fabric distributes an appropriate address and produces a `chipselect` signal for each slave port. Address decoding logic simplifies component design in the following ways:

- The system interconnect fabric selects a slave port whenever it is being addressed by a master. Slave components do not need to decode the address to determine when they are selected.
- Slave port addresses are properly aligned for the slave port.
- SOPC Builder automatically generates address decoding logic to implement the memory map specified in the GUI. Therefore, changing the system memory map does not involve manually editing HDL.

Figure 2-2 shows a block diagram of the address-decoding logic for one master and two slave ports. Separate address-decoding logic is generated for every master port in a system.

As shown in Figure 2-2, the address decoding logic handles the difference between the master address width ( $M$ ) and the individual slave address widths ( $S$  and  $T$ ). It also maps only the necessary master address bits to access words in each slave port’s address space.

**Figure 2-2. Block Diagram of Address Decoding Logic**

In SOPC Builder, the user-configurable aspects of address decoding logic are controlled by the **Base** setting in the list of active components on the **System Contents** tab, as shown in [Figure 2-3](#).

**Figure 2-3. Base Settings in SOPC Builder Control Address Decoding**

Module Name	Description	Base	End	IRQ

high_res_timer	Interval timer	0x02120820	0x0212083F	3

## Datapath Multiplexing

Datapath multiplexing logic in the system interconnect fabric drives the writedata from the granted master to the selected slave, and from the readdata from the selected slave back to the requesting master.

[Figure 2-4](#) shows a block diagram of the datapath multiplexing logic for one master and two slave ports. SOPC Builder generates separate datapath multiplexing logic for every master port in the system.

**Figure 2-4. Block Diagram of Datapath Multiplexing Logic**

In SOPC Builder, the generation of datapath multiplexing logic is specified using the connections panel on the **System Contents** page, as shown in [Figure 2-5](#).

**Figure 2-5. Connection Panel Settings in SOPC Builder Control Datapath Multiplexing**

## Wait-State Insertion

Wait states extend the duration of a transfer by one or more cycles. Wait-state insertion logic accommodates the timing needs of each slave port, and coordinates the master port to wait until the slave can proceed. System interconnect fabric inserts wait states into a transfer when the target slave port cannot respond in a single clock cycle. System interconnect fabric also inserts wait states in cases when slave read-enable and write-enable signals have setup or hold time requirements.

Wait-state insertion logic is a small finite-state machine that translates control signal sequencing between the slave side and the master side. [Figure 2-6](#) shows a block diagram of the wait-state insertion logic between one master and one slave.

**Figure 2-6. Block Diagram of Wait-State Insertion Logic**

System interconnect fabric can force a master port to wait for several reasons in addition to the wait state needs of a slave port. For example, arbitration logic in a multimaster system can force a master port to wait until it is granted access to a slave port.

SOPC Builder generates wait-state insertion logic based on the properties of all slave ports in the system.

## Pipeline Read Transfers

The Avalon-MM interface supports pipelined read transfers, allowing a pipelined master port to start multiple read transfers in succession without waiting for the prior transfers to complete. Pipelined transfers allow master-slave pairs to achieve higher throughput, even though the slave port might require one or more cycles of latency to return data for each transfer.

SOPC Builder generates system interconnect fabric with pipeline management logic to take advantage of pipelined components wherever possible, based on the pipeline properties of each master-slave pair in the system. Regardless of the pipeline latency of a target slave port, SOPC Builder guarantees that read data arrives at each master port in the order requested. Because master and slave ports often have mismatched pipeline latency, system interconnect fabric often contains logic to reconcile the differences. Many cases are possible, as shown in [Table 2-1](#).

Master Port	Slave Port	Pipeline Management Logic Structure
No Pipeline	No Pipeline	The system interconnect fabric does not instantiate logic to handle pipeline latency.
No Pipeline	Pipelined with Fixed or Variable Latency	The system interconnect fabric forces the master port to wait through any slave-side latency cycles. This master-slave pair gains no benefits of pipelining, because the master port is not pipelined and therefore waits for each transfer to complete before beginning a new transfer. However, while the master port is waiting, the slave port can accept transfers from a different master port.
Pipelined	No Pipeline	The system interconnect fabric carries out the transfer as if neither port were pipelined, forcing the master port to wait until the slave port returns data.
Pipelined	Pipelined with Fixed Latency	The system interconnect fabric coordinates the master port to capture data at the exact clock cycle when data is valid on the slave port. This case enables this master-slave pair to achieve maximum throughput performance.
Pipelined	Pipelined with Variable Latency	This is the simplest pipelined case, in which the slave port asserts a signal when its readdata is valid, and the master port captures the data. This case enables this master-slave pair to achieve maximum throughput performance.

SOPC Builder generates logic to handle pipeline latency based on the properties of the master and slave ports in the system. When configuring a system in SOPC Builder, there are no settings that directly control the pipeline management logic in the system interconnect fabric.

## Native Address Alignment and Dynamic Bus Sizing

SOPC Builder generates system interconnect fabric to accommodate master and slave ports with unmatched data widths. Address alignment affects how slave data is aligned in a master port's address space, in the case that the master and slave data widths are different. Address alignment is a property of each slave port, and can be different for each slave port in a system. A slave port can declare itself to use one of the following:

- Native address alignment
- Dynamic bus sizing

Table 2–2 demonstrates native address alignment and dynamic bus sizing for a 32-bit master port connected to a 16-bit slave port (a 2:1 ratio). In this example, the slave port is mapped to base address *BASE* in the master port's address space. In Table 2–2, *OFFSET* refers to the offset into the 16-bit slave address space.

32-bit Master Address	Data with Native Alignment	Data with Dynamic Bus Sizing
<i>BASE</i> + 0x0 (word 0)	0x0000 : <i>OFFSET</i> [0]	<i>OFFSET</i> [1] : <i>OFFSET</i> [0]
<i>BASE</i> + 0x4 (word 1)	0x0000 : <i>OFFSET</i> [1]	<i>OFFSET</i> [3] : <i>OFFSET</i> [2]
<i>BASE</i> + 0x8 (word 2)	0x0000 : <i>OFFSET</i> [2]	<i>OFFSET</i> [5] : <i>OFFSET</i> [4]
<i>BASE</i> + 0xC (word 3)	0x0000 : <i>OFFSET</i> [3]	<i>OFFSET</i> [7] : <i>OFFSET</i> [6]
...	...	...
<i>BASE</i> + 4 <i>N</i> (word <i>N</i> )	0x0000 : <i>OFFSET</i> [ <i>N</i> ]	<i>OFFSET</i> [2 <i>N</i> +1] : <i>OFFSET</i> [2 <i>N</i> ]

SOPC Builder generates appropriate address-alignment logic based on the properties of the master and slave ports in the system. When configuring a system in SOPC Builder, there are no settings that directly control the address alignment in the system interconnect fabric.

### Dynamic Bus Sizing

Dynamic bus sizing hides the details of interfacing a narrow component device to a wider master port, and vice versa. When an *N*-bit master port accesses a slave port with dynamic bus sizing, the master port operates exclusively on full *N*-bit words of data, without awareness of the slave data width.

When using dynamic bus sizing, the slave data width with units of bytes must be a power of two.

Dynamic bus sizing provides the following benefits:

- Eliminates the need to create address-alignment hardware manually.
- Reduces design complexity of the master component.
- Enables any master port to access any memory device, regardless of the data width.

In the case of dynamic bus sizing, the system interconnect fabric includes a small finite state machine that reconciles the difference between master and slave data widths. The behavior is different depending on whether the master data width is wider or narrower than the slave.

### *Wider Master*

In the case of a wider master, the dynamic bus-sizing logic accepts a single, wide transfer on the master side, and then performs multiple narrow transfers on the slave side. For a data-width ratio of  $N:1$ , the dynamic bus-sizing logic generates up to  $N$  slave transfers for each master transfer. The master port waits while multiple slave-side transfers complete; the master transfer ends when all slave-side transfers end.

Dynamic bus-sizing logic uses the master-side byte-enable signals to generate appropriate slave transfers. The dynamic bus-sizing logic performs as many slave-side transfers as necessary to write or read the specified byte lanes.

### *Narrower Master*

In the case of a narrower master, one transfer on the master side generates one transfer on the slave side. In this case, multiple master word addresses map to a single offset in the slave memory space. The dynamic bus-sizing logic maps each master address to a subset of byte lanes in the appropriate slave offset. All bytes of the slave memory are accessible in the master address space.

Table 2-3 demonstrates the case of a 32-bit master port accessing a 64-bit slave port with dynamic bus sizing. In the table, offset refers to the offset into the slave port memory space.

<b>Table 2-3. 32-Bit Master View of 64-Bit Slave with Dynamic Bus Sizing (Part 1 of 2)</b>	
<b>32-bit Address</b>	<b>Data</b>
0x00000000 (word 0)	OFFSET [0] <sub>31..0</sub>
0x00000004 (word 1)	OFFSET [0] <sub>63..32</sub>

**Table 2–3. 32-Bit Master View of 64-Bit Slave with Dynamic Bus Sizing (Part 2 of 2)**

32-bit Address	Data
0x00000008 (word 2)	OFFSET [1] <sub>31..0</sub>
0x0000000C (word 3)	OFFSET [1] <sub>63..32</sub>

In the case of a read transfer, the dynamic bus-sizing logic multiplexes the appropriate byte lanes of the slave data to the narrow master port. In the case of a write transfer, the dynamic bus-sizing logic uses slave-side byte-enable signals to write only to the appropriate byte lanes.

## Native Address Alignment

Slave ports that access address-mapped registers inside the component generally use native address alignment. The defining properties of native address alignment are:

- Each slave offset (that is, word) maps to exactly one master word, regardless of the data width of the ports.
- One transfer on the master port generates exactly one transfer on the slave port.

In the case of native address alignment, system interconnect fabric maps all slave data bits to the lower bits of the master data, and fills any remaining upper bits with zero. System interconnect fabric performs simple wire-mapping in the datapath, but nothing else.

Native address alignment is only valid if the master data width is equal to or wider than the slave data width. If an  $N$ -bit master port is connected to a wider slave with native alignment, then the master port can access only the lower  $N$  data bits at each offset in the slave.

Native address alignment prevents use of the slave with narrow masters and some bridge implementations, and is not recommended for new components.

## Arbitration for Multimaster Systems

System interconnect fabric supports systems with multiple master components. In a system with multiple master ports, such as the system pictured in [Figure 2–1 on page 2–3](#), the system interconnect fabric provides shared access to slave ports using a technique called slave-side arbitration. Slave-side arbitration determines which master port gains access to a specific slave port in the event that multiple master ports attempt to access the same slave port at the same time.

The multimaster architecture used by system interconnect fabric offers the following benefits:

- Eliminates the need to create arbitration hardware manually.
- Allows multiple master ports to transfer data simultaneously. Unlike traditional host-side arbitration architectures in which each master must wait until it is granted access to the shared bus, multiple Avalon-MM masters can simultaneously perform transfers with independent slaves. Arbitration logic stalls a master port only when multiple master ports attempt to access the same slave port during the same cycle.
- Eliminates unnecessary master-slave connections. The connection between a master port and a slave port exists only if it is specified in SOPC Builder. If a master port never initiates transfers to a specific slave port, no connection is necessary, and therefore SOPC Builder does not waste logic resources to connect the two ports.
- Provides configurable arbitration settings, and arbitration for each slave port is specified independently. For example, you can grant one master port the most access to a particular slave port, while other master ports have more access to other slave ports.
- Simplifies master component design. The details of arbitration are encapsulated inside the system interconnect fabric. Each Avalon-MM master port connects to the system interconnect fabric as if it is the only master port in the system. As a result, you can reuse a component in single-master and multimaster systems without requiring design changes to the component.

This section discusses the architecture of the system interconnect fabric generated by SOPC Builder for multimaster systems.

### Traditional Shared Bus Architectures

As a frame of reference for the discussion of multiple masters and arbitration, this section describes traditional bus architectures.

In traditional bus architectures, one or more bus masters and bus slaves connect to a shared bus, consisting of wires on a printed circuit board. A single arbiter controls the bus (that is, the path between bus masters and bus slaves), so that multiple bus masters do not simultaneously drive the

bus. Each bus master requests control of the bus from the arbiter, and the arbiter grants access to a single master at a time. Once a master has control of the bus, the master performs transfers with a bus slave. If multiple masters attempt to access the bus at the same time, the arbiter allocates the bus resources to a single master based on fixed arbitration rules, forcing all other masters to wait. For example, the priority arbitration scheme—in which the arbiter always grants control to the master with the highest priority—is used in many existing bus architectures.

Figure 2–7 illustrates the bus architecture for a traditional processor system. Access to the shared system bus becomes the bottleneck for throughput: only one master has access to the bus at a time, which means that other masters are forced to wait and only one slave can transfer data at a time.

**Figure 2–7. Bus Architecture in a Traditional Microprocessor System**

## Slave-Side Arbitration

The multimaster architecture used by system interconnect fabric eliminates the bottleneck for access to a shared bus, because the system does not have shared bus signals. Avalon-MM master-slave pairs are connected by dedicated paths. A master port never waits to access a slave port, unless a different master port attempts to access the same slave port at the same time. As a result, multiple master ports can be active at the same time, simultaneously transferring data with independent slave ports.

A multimaster Avalon-MM system requires arbitration, but only when two masters contend for the same slave port. This arbitration is called slave-side arbitration, because it is implemented at the point where two (or more) master ports connect to a single slave. Master ports contend for individual slave ports, not for a shared bus resource.

For example, [Figure 2-1 on page 2-3](#) demonstrates a system with two master ports (a CPU and a DMA controller) sharing a slave port (an SDRAM controller). Arbitration is performed at the SDRAM slave port; the arbiter dictates which master port gains access to the slave port if both master ports initiate a transfer with the slave port in the same cycle.

[Figure 2-8](#) focuses on the two master ports and the shared slave port, and shows additional detail of the data, address, and control paths. The arbiter logic multiplexes all address, data, and control signals from a master port to a shared slave port.

**Figure 2-8. Detailed View of Multimaster Connections**

## Arbiter Details

SOPC Builder generates an arbiter for every slave port, based on arbitration parameters specified in SOPC Builder. The arbiter logic performs the following functions for its slave port:

- Evaluates the address and control signals from each master port and determines which master port, if any, gains access to the slave next.
- Grants access to the chosen master port and forces all other requesting master ports to wait.
- Uses multiplexers to connect address, control, and datapaths between the multiple master ports and the slave port.

Figure 2–9 shows the arbiter logic in an example multimaster system with two master ports, each connected to two slave ports.

Figure 2–9. Block Diagram of Arbiter Logic

### Arbitration Rules

This section describes the rules by which the arbiter grants access to master ports when they contend.

#### Setting Arbitration Parameters in SOPC Builder

You specify the arbitration shares for each master using the connection panel on the **System Contents** tab of SOPC Builder, as shown in Figure 2–10.

Figure 2–10. Arbitration Settings on the System Contents Tab

Module Name	Description	Clock
cpu	Nios II Processor - Alte...	clk
instruction_master	Master port	
data_master	Master port	
1 jtag_debug_module	Slave port	
1 sys_clk_timer	Interval timer	clk
1 ext_ram_bus	Avalon Tri-State Bridge	clk
ext_flash	Flash Memory (Commo...	
ext_ram	IDT71V416 SRAM	
1 epcs_controller	EPCS Serial Flash Cont...	clk
lan91c111	LAN91c111 Interface (...)	
1 jtag_uart	JTAG UART	clk

The arbitration settings are hidden by default. To see them, on the View menu, click **Show Arbitration**.

### *Fairness-Based Shares*

Arbiter logic uses a fairness-based arbitration scheme. In a fairness-based arbitration scheme, each master port pair has an integer value of *transfer shares* with respect to a slave port. One share represents permission to perform one transfer.

For example, assume that two master ports continuously attempt to perform back-to-back transfers to a slave port. Master 1 is assigned three shares and Master 2 is assigned four shares. In this case, the arbiter grants Master 1 access for three transfers, then Master 2 for four transfers. This cycle repeats indefinitely. [Figure 2-11](#) demonstrates this case, showing each master port's transfer request output, wait request input (which is driven by the arbiter logic), and the current master with control of the slave.

**Figure 2-11. Arbitration of Continuous Transfer Requests from Two Master Ports**

If a master stops requesting transfers before it exhausts its shares, it forfeits all its remaining shares, and the arbiter grants access to another requesting master. See [Figure 2-12](#). After completing one transfer, Master 2 stops requesting for one clock cycle. As a result, the arbiter grants access back to Master 1, which gets a replenished supply of shares.

**Figure 2-12. Arbitration of Two Masters with a Gap in Transfer Requests**

### *Round-Robin Scheduling*

When multiple master ports contend for access to a slave port, the arbiter grants shares in round-robin manner. Round-robin scheduling drives a request interface according to space available and data available credit interfaces. At every slave transfer, only requesting master ports are included in the arbitration.

### *Burst Transfers*

Avalon-MM burst transfers grant a master port uninterrupted access to a slave port for a specified number of transfers. The master port specifies the number of transfers when it initiates the burst. Once a burst begins between a master-slave pair, arbiter logic does not allow any other master port to access the slave port until the burst completes. For further information, refer to [“Burst Management” on page 2–18](#).

### *Minimum Share Value*

A component design can declare the minimum number of shares in each round-robin cycle, which affects how the arbiter grants access. For example, if a slave port has a minimum share value of ten, then the arbiter will grant at least ten shares to any master port when it begins a sequence of transfer requests. The arbiter might grant more shares, if the master port is assigned more shares in SOPC Builder.

By declaring a minimum share value of  $N$ , a slave port declares that it is more efficient at handling continuous sequential transfers of length  $N$ . Accessing the slave port in sequences less than  $N$  incurs performance penalties that might prevent the slave port from achieving higher performance. By nature, continuous back-to-back master transfers tend to access sequential addresses. However, there is no requirement that the master port perform transfers to sequential addresses.

Burst transfers provide even higher performance for continuous transfers when they are guaranteed to access sequential addresses. The minimum share value does not apply to slave ports that support bursts; the burst length takes precedence over minimum share value. Refer to [“Burst Management” on page 2–18](#) for information.

You specify the arbitration shares for each master using the connection panel on the **System Contents** tab of SOPC Builder, as shown in [Figure 2–13](#).

## Burst Management

System interconnect fabric provides burst management logic to accommodate the burst capabilities of each port in the system, including ports that do not support burst transfers. Burst management logic is a finite state machine that translates the sequencing of address and control signals between the slave side and the master side.

The maximum burst length for each port is determined by the component design and is independent of other ports in the system. Therefore, a particular master port might be capable of initiating a burst longer than a slave port's maximum supported burst length. In this case, the burst management logic translates the master burst into smaller slave bursts, or into individual slave transfers if the slave port does not support bursts. Until the master port completes the burst, the arbiter logic prevents other master ports from accessing the target slave port.

For example, if a master port initiates a burst of 16 transfers to a slave port with maximum burst length of 8, the burst management logic initiates two bursts of length 8 to the slave port. If a master port initiates a burst of 16 transfers to a slave port that does not support bursts, the burst management logic initiates 16 separate transfers to the slave port.

## Clock Domain Crossing

SOPC Builder generates clock-domain crossing (CDC) logic that hides the details of interfacing components operating in asynchronous clock domains. The system interconnect fabric upholds the Avalon-MM protocol with each port independently, and therefore each Avalon-MM port need only be aware of its own clock domain. The system interconnect fabric logic propagates transfers across clock domain boundaries automatically.

The CDC logic in system interconnect fabric provides the following benefits that simplify system design efforts:

- Allows component interfaces to operate at a different clock frequency than system logic.
- Eliminates the need to design CDC hardware manually.
- Each Avalon-MM port operates in only one clock domain, which reduces design complexity of components.
- Enables master ports to access any slave port without communication with the slave clock domain.
- Allows you to focus performance optimization efforts only on components that require fast clock speed.

### Description of Clock Domain-Crossing Logic

The CDC logic consists of two finite state machines (FSM), one in each clock domain, that use a simple hand-shaking protocol to propagate transfer control signals (read request, write request, and the master wait-request signals) across the clock boundary. [Figure 2-14](#) shows a block diagram of the clock domain crossing logic between one master and one slave port.

**Figure 2–14. Block Diagram of Clock Domain-Crossing Logic**

The Synchronizer blocks in [Figure 2–14](#) use multiple stages of flip-flops to eliminate the propagation of metastable events on the control signals that enter the handshake FSMs.

The CDC logic works with any clock ratio. Altera® tests the CDC logic extensively on a variety of system architectures, both in simulation and in hardware, to ensure that the logic functions correctly.

The typical sequence of events for a transfer across the CDC logic is described below:

1. Master port asserts address, data, and control signals.
2. The master handshake FSM captures the control signals, and immediately forces the master port to wait.

The FSM uses only the control signals, not address and data. For example, the master port simply holds the address signal constant until the slave side has safely captured it.

3. Master handshake FSM initiates a transfer request to the slave handshake FSM.
4. The transfer request is synchronized to the slave clock domain.
5. The slave handshake FSM processes the request, performing the requested transfer with the slave port.
6. When the slave transfer completes, the slave handshake FSM sends an acknowledge back to the master handshake FSM.
7. The acknowledge is synchronized back to the master clock domain.
8. The master handshake FSM completes the transaction by releasing the master port from the wait condition.

Transfers proceed as normal on the slave and the master side, without a special protocol to handle crossing clock domains. From the perspective of a slave port, there is nothing different about a transfer initiated by a master port in a different clock domain. From the perspective of a master port, a transfer across clock domains simply requires extra clock cycles. Similar to other transfer delay cases (for example, arbitration delay or wait states on the slave side), the system interconnect fabric simply forces the master port to wait until the transfer terminates. As a result, latency-aware master ports do not benefit from pipelining when performing transfers to a different clock domain.

### Location of Clock Domain Crossing Logic

SOPC Builder automatically determines where to insert the CDC logic, based on the system contents and the connections between components. SOPC Builder places CDC logic to maintain the highest transfer rate for all components. SOPC Builder evaluates the need for CDC logic on each slave port independently, and generates CDC logic wherever necessary.

## Duration of Transfers Crossing Clock Domains

CDC logic extends the duration of master transfers across clock domain boundaries. In the worst case, each transfer is extended by five master clock cycles and five slave clock cycles. The components of this delay are the following:

- Four additional master clock cycles, due to the master-side clock synchronizer
- Four additional slave clock cycles, due to the slave-side clock synchronizer
- One additional clock in each direction, due to potential metastable events as the control signals cross clock domains

Systems that require higher performance clock crossing logic should use the Avalon-MM clock crossing bridge instead of the automatically inserted CDC logic. The clock-crossing bridge includes a buffering mechanism, so that multiple reads and writes can be pipelined. After paying the initial penalty for the first read or write, there is no additional latency penalty for pending reads and writes, increasing throughput by up to four times, at the expense of added logic resources.

For more information, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook*.

## Implementing Multiple Clock Domains in SOPC Builder

You specify the clock domains used by your system on the **System Contents** tab of SOPC Builder. You define the input clocks to the system with the **Clock Settings** table, shown in [Figure 2–15](#). Clock sources can be driven by external input signals to the system module, or by PLLs inside the system module. Clock domains are differentiated based on the name of the clock. It is possible to create multiple asynchronous clocks with the same frequency.

**Figure 2–15. Clock Settings on the System Contents Tab**

Clock	Source	MHz	Pipeline
clk_85	External	85.0	<input type="checkbox"/>
clk_233	c0 from pll	233.75	<input checked="" type="checkbox"/>
click to add...			<input type="checkbox"/>

You specify which clock drives which components using the table of active components after you define the system clocks, as shown in [Figure 2-16](#).

**Figure 2-16. Assigning Clocks to Components**

Module Name	Description	Clock	Base	End	IRQ
<b>high_res_timer</b>	Interval timer	clk	0x02120820	0x0212083F	3
<b>seven_seg_pio</b>	PIO (Parallel I/O)	clk	0x02120890	0x0212089F	
<b>reconfig_request_pio</b>	PIO (Parallel I/O)	fastclk	0x021208A0	0x021208AF

<b>write_buffer</b>	On-Chip Memory (RAM ...)	fastclk	0x00802000	0x00802FFF	

Alternatively, the clock patch panel can be used.

This section describes the hardware structure and functionality of the Avalon-MM clock-crossing bridge component.

## Component Overview

The Avalon-MM clock-crossing bridge allows you to connect Avalon-MM master and slave ports that operate in different clock domains. Without a bridge, SOPC Builder automatically includes generic CDC logic in the system interconnect fabric, but it does not provide optimal performance for high-throughput applications. The CDC logic uses a four-way handshake mechanism so that each read and write takes multiple cycles in each direction. Because the clock-crossing bridge includes a buffering mechanism, you can pipeline multiple reads and writes. After an initial penalty for the first read or write, there is no additional latency penalty for pending reads and writes, increasing throughput by up to four times, at the expense of additional logic resources. The clock-crossing bridge has parameterizable FIFOs for master-to-slave and slave-to-master signals, which allows burst transfers across clock domains.

The Avalon-MM clock-crossing bridge component is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system.

## Functional Description

[Figure 2-17](#) shows a block diagram of the Avalon-MM clock-crossing bridge component. The following sections describe the component's hardware functionality.

**Figure 2-17. Avalon-MM Clock-Crossing Bridge Block Diagram**

### Interfaces

The bridge interface comprises an Avalon-MM slave port and an Avalon-MM master port. The data width of the ports is configurable, which affects the size of the bridge hardware and how SOPC Builder generates dynamic bus sizing logic in the system interconnect fabric. Both ports support Avalon-MM pipelined transfers with variable latency. Both ports optionally support bursts of user-configurable length.

### Clock Domain Crossing Logic and FIFOs

Two FIFOs in the bridge transport address, data, and control signals across the clock-domains. One FIFO captures data traveling in the master-to-slave direction, and the other FIFO captures data in the slave-to-master direction. CDC logic surrounding the FIFOs coordinates the details of passing data across the clock-domain boundaries and ensures that the FIFOs do not overflow or underflow.

The signals that pass through the master-to-slave FIFO include:

- `writedata`
- `address`
- `read`
- `write`
- `nativeaddress`
- `byteenable`
- `burstcount`, when bursts are allowed.

The signals that pass through the slave-to-master FIFO include:

- `readdata`
- `readdatavalid`
- `endofpacket`

The depth of each FIFO is configurable. Because there are more signals traveling in the master-to-slave direction, changing the depth of the master-to-slave FIFO has a greater impact on the memory utilization of the bridge.

For read transfers across the bridge, the FIFOs in both directions incur latency for data to return from the slave. To avoid paying a latency penalty for each transfer, the master can issue multiple reads which are queued in the FIFO. The slave of the bridge asserts `readdatavalid` when it drives valid data and asserts `waitrequest` when it is not ready to accept more reads.

For write transfers, the master-to-slave FIFO causes a delay between the master-to-bridge transfers and the corresponding bridge-to-slave transfers. Because Avalon-MM write transfers do not require an acknowledge from the slave, multiple write transfers from master-to-bridge might complete by the time the bridge initiates the corresponding bridge-to-slave transfers.

### *Burst Support*

The bridge can optionally support bursts with configurable maximum burst length. When configured to support bursts, the bridge propagates bursts between master-slave pairs, up to the maximum burst length. Not having burst support is equivalent to a maximum burst length of one. In this case, the system interconnect fabric automatically deconstructs master-to-bridge bursts into a sequence of individual transfers.

When the bridge is configured to support bursts, the slave-to-master FIFO depth must be configured deeply enough to capture all burst read data without overflowing. The master ports connected to the bridge could potentially fill the master-to-slave FIFO with read burst requests; therefore, the minimum slave-to-master FIFO depth is described in the following equation:

(1)      *No Bursts:*  
             *minimum depth = master-to-slave FIFO depth + max slave latency;*

*With Bursts:*  
             *minimum depth*  
                   = (master-to-slave FIFO depth + max slave latency) \* (max burst size);

In both cases, the minimum depth is rounded up to the nearest power of two.

### *Example System with Avalon-MM Clock-Crossing Bridges*

Figure 2-18 uses Avalon-MM clocking crossing bridges to separate slave components into two groups. The low-performance slave components are placed behind a single bridge and clocked at a low speed. The high performance components are placed behind a second bridge and clocked at a higher speed. By inserting clock-crossing bridges in the system, you optimize the interconnect fabric and allow the Quartus II Fitter to expend effort optimizing paths that require minimal propagation delay.

Figure 2-18. One Avalon-MM Master with Two Groups of Avalon-MM Slaves

## Instantiating the Avalon-MM Clock-Crossing Bridge in SOPC Builder

You use the Avalon-MM Clock-Crossing Bridge MegaWizard® interface in SOPC Builder to specify the hardware features. This section describes the options available on the **Parameter Settings** page of the Megawizard interface.

- **Master-to-Slave FIFO**—These options specify the size and structure of the master-to-slave FIFO.
  - **FIFO Depth**—Determines the depth of the FIFO.
  - **Construct FIFO from registers**—When this option is on, the FIFO uses registers as storage instead of embedded memory blocks. Turning on this option can considerably increase the size of the bridge hardware and lower the  $f_{MAX}$ .
- **Slave-to-Master FIFO**—These options specify the size and structure of the slave-to-master FIFO.
  - **FIFO Depth**—Determines the depth of the FIFO.
  - **Construct FIFO from registers**—When this option is on, the FIFO uses registers as storage instead of embedded memory blocks. Turning on this option can considerably increase the size of the bridge hardware.
- **Data Width**—Determines the data width of the master and slave ports on the bridge, and affects the size of both FIFOs.

For the highest bandwidth, set **Data Width** to be as wide as the widest master port connected to the bridge.

- **Allow Bursts**—Includes logic for the bridge's master and slave ports to support bursts. This option restricts the minimum depth for the slave-to-master FIFO.
- **Maximum Burst Size**—Determines the maximum length of bursts for the bridge to support, when **Allow Bursts** is turned on.

# Interrupts

In systems with slave ports that generate interrupt requests (IRQs), the system interconnect fabric includes interrupt controller logic. A separate interrupt controller is generated for each master port that accepts interrupts. The interrupt controller aggregates IRQ signals from all slave ports, and maps slave IRQ outputs to user-specified values on the master IRQ inputs.

## Software Priority

In the software priority configuration, the system interconnect fabric passes IRQs directly from slave to master port, without making any assumptions about IRQ priority. In the event that multiple slave ports assert their IRQs simultaneously, the master logic (presumably under software control) determines which IRQ has highest priority, then responds appropriately.

Using software priority, the interrupt controller can handle up to 32 slave IRQ inputs. The interrupt controller generates a 32-bit signal `irq[31..0]` to the master port, and simply maps slave IRQ signals to the bits of `irq[31..0]`. Any unassigned bits of `irq[31..0]` are permanently disabled. [Figure 2-19](#) shows an example of the interrupt controller mapping the IRQs on four slave ports to `irq[31..0]` on a master port.

**Figure 2-19. IRQ Mapping Using Software Priority**

## Hardware Priority

In the hardware priority configuration, in the event that multiple slaves assert their IRQs simultaneously, the system interconnect fabric (that is, hardware logic) identifies the IRQ of highest priority and passes only that IRQ number to the master port. An IRQ of lesser priority is undetectable until a master port clears all IRQs of higher priority.

Using hardware priority, the interrupt controller can handle up to 64 slave IRQ signals. The interrupt controller generates a 1-bit `irq` signal to the master port, signifying that one or more slave ports have generated an IRQ. The controller also generates a 6-bit `irqnumber` signal, which outputs the encoded value of the highest pending IRQ. See [Figure 2–20](#).

**Figure 2–20. IRQ Mapping Using Hardware Priority**

## Assigning IRQs in SOPC Builder

You specify IRQ settings on the **System Contents** tab of SOPC Builder. After adding all components to the system, you make IRQ settings for all slave ports that can generate IRQs, with respect to each master port. For

each slave port, you can either specify an IRQ number, or specify not to connect the IRQ. Figure 2–21 shows the IRQ settings for multiple slave IRQs that drive the master component named `cpu`.

Figure 2–21. Assigning IRQs in SOPC Builder

## Reset Distribution

The system interconnect fabric generates and distributes a system-wide reset pulse to all logic in the system module. The system interconnect fabric distributes the reset signal conditioned for each clock domain. The duration of the reset signal is at least one clock period.

The system interconnect fabric asserts the system-wide reset in the following conditions:

- The global reset input to the system module is asserted.
- Any slave port asserts its `resetrequest` signal.

All components must enter a well-defined reset state whenever the system interconnect fabric asserts the system-wide reset. The timing of the reset signal is asynchronous to the operation of transfers. Resets are asserted asynchronously and deasserted synchronously to the associated clock.

### Introduction

Avalon® Streaming interconnect fabric connects high-bandwidth, low latency components that use the Avalon Streaming (Avalon-ST) interface. It creates datapaths for unidirectional traffic including multichannel streams, packets, and DSP data. This chapter describes the Avalon-ST interconnect fabric and its use in connecting components with Avalon-ST interfaces. Descriptions of specific adapters and their use in streaming systems can be found in the following sections:

- “Adapters” on page 3-3
- “Multiplexer Examples” on page 3-5

### High-Level Description

Avalon-ST interconnect fabric is logic generated by SOPC Builder. Using SOPC Builder, you specify how Avalon-ST source and sink ports connect. SOPC Builder creates a high performance point-to-point interconnect between the two components. The Avalon-ST interconnect is flexible and can be used to implement on-chip interfaces for industry standard telecommunications and data communications cores, such as Ethernet IEEE 802.3 MAC and SPI 4.2. In all cases, bus widths, packets, and error conditions are custom-defined.

Figure 3-1 illustrates the simplest system example that generates an interconnect between the source and sink. This source-sink pair includes only the data and valid signals.

**Figure 3-1. Interconnect for a Simple Avalon Streaming Source-Sink Pair**

Figure 3-2 illustrates a more extensive interface that includes signals indicating the start and end of packets, channel numbers, error conditions, and back pressure.

**Figure 3–2. Avalon Streaming Interface for Packet Data**

All data transfers using Avalon-ST interconnect occur synchronously to the rising edge of the associated clock interface. All outputs from the source interface, including the data, channel, and error signals, must be registered on the rising edge of the clock. Registers are not required for inputs at the sink interface. Registering signals at the source provides for high frequency operation while eliminating back-to-back registration with no intervening logic. There is no inherent maximum performance of the interconnect. Throughput for a system depends on the components and how they are connected.

Although you do not have to register signals in the sink-to-source direction, register such signals if more than a trivial amount of logic is needed to generate them. Registering signals at both ends of the source-to-sink connection can increase the  $f_{\text{MAX}}$  at which the system can run.

For details about the Avalon-ST interface protocol, refer to the *Avalon Streaming Interface Specification* available at [www.altera.com](http://www.altera.com).

## Avalon Streaming and Avalon Memory-Mapped Interfaces

The Avalon-ST and Avalon Memory-Mapped (Avalon-MM) interfaces are complimentary. High bandwidth components with streaming data typically use Avalon-ST interfaces for the high throughput datapath. These components can also use Avalon Memory-Mapped interfaces to provide an access point for control. In contrast to the Avalon-MM interconnect, which can be used to create a wide variety of topologies, the Avalon-ST interconnect fabric always creates a point-to-point between a single data source and data sink, as [Figure 3–3](#) illustrates. There are two connection pairs in this figure:

- The Data Source in the RX Interface transfers data to the Data Sink in the FIFO.

- The Data Source in the FIFO transfers data to the TX Interface Data Sink.

In [Figure 3–3](#), the Avalon-MM interface allows a processor to access the data source, FIFO, or data sink to provide system control.

**Figure 3–3. Use of the Avalon Memory-Mapped and Streaming Interfaces**

## Adapters

Adapters are configurable SOPC Builder components that are part of streaming interconnect fabric. They are used to connect source and sink interfaces that are not exactly the same without affecting the semantics of the data. SOPC Builder includes the following three adapters:

- Data Format Adapter
- Timing Adapter
- Channel Adapter

The Insert Avalon-ST Adapters command on the System menu allows you to insert an adapter so that you can connect a data source to a data sink of differing byte sizes in the SOPC Builder system.

For complete information about these adapters, refer to the *Avalon Streaming Interconnect Components* chapter in volume 4 of the *Quartus II Handbook*.

The following sections provide an overview of these adapters.

## Data Format Adapter

The data format adapter allows you to connect interfaces that have different values for the parameters defining the data signal. One of the most common uses of this adapter is to convert buses of different widths. [Figure 3-4](#) shows an adapter that allows a connection between a 128-bit input bus and three 32-bit output buses.

**Figure 3-4. Avalon Streaming Interconnect Fabric with Data Format Adapter**

## Timing Adapter

The timing adapter allows you to connect component interfaces that require a different number of cycles before driving or receiving data. This adapter inserts a FIFO between the source and sink to buffer data or pipeline stages to delay the backpressure signals. The timing adapter can also be used to connect interfaces that support the `ready` signal and those that do not.

### Channel Adapter

The channel adapter provides adaptations between interfaces that have different support for the channel signal or channel-related parameters. For example, if the source channel is narrower than the sink channel, you can use this adapter to connect them. The high-order bits of the sink channel are connected to zero. You can also use this adapter to connect a source with a wider channel to a sink with a narrower channel; however, this usage produces a warning that data may be lost.

## Multiplexer Examples

You can combine the three adapters referenced above with streaming components to create datapaths whose input and output streams have different properties. The following sections provide three examples of datapaths constructed using SOPC Builder whose output stream is higher performance than the input stream:

- The first example shows an output with double the throughput of each interface with a corresponding doubling of the clock frequency.
- The second example doubles the data width.
- The third boosts the frequency of a stream by 10% multiplexing input data from 2 sources.

### Example to Double Clock Frequency

Figure 3-5 illustrates a datapath that uses the dual clock version of the on-chip FIFO memory and Avalon-ST channel multiplexer to merge the 100 MHz input from two streaming data sources into a single 200 MHz streaming output. As Figure 3-5 illustrates, this example increases throughput by increasing the frequency and combining inputs.

Figure 3-5. Datapath that Doubles the Clock Frequency

### Example to Double Data Width and Maintain Frequency

Figure 3-6 illustrates a datapath that uses the data format adapter and Avalon-ST channel multiplexer to convert two, 8-bit inputs running at 100 MHz to a single 16-bit output at 100 MHz.

Figure 3-6. Datapath to Double Data Width and Maintain Original Frequency

### Example to Boost the Frequency

Figure 3-7 illustrates a datapath that uses the dual clock version of the on-chip FIFO memory to boost the frequency of input data from 100 MHz to 110 MHz by sampling two input streams at differential rates. In this example, the on-chip FIFO memory has an input clock frequency of 100 MHz and an output clock frequency of 110 MHz. The channel multiplexer runs at 110 MHz and samples one input stream 27.3 percent of the time and the second 72.7 percent of the time.

Figure 3-7. Datapath to Boost the Clock Frequency

## Document Revision History

Table 3–1 shows the revision history for this chapter.

<i>Table 3–1. Document Revision History</i>		
<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007, v7.2.0	No changes for this release.	—
May 2007, v7.1.0	Initial release.	The Avalon-ST Data Format Adapter, Timing Adapter and Channel Adapter are new components provided in the Quartus II software v7.1 release.

### Introduction

An SOPC Builder *component* is a hardware design block available within SOPC Builder that can be instantiated in an SOPC Builder system. This chapter defines SOPC Builder components, with emphasis on the structure of custom components.

A component includes the following:

- The HDL description of the component's hardware
- A description of the interface to the component hardware, such as the names and types of I/O signals.
- A description of any parameters that specify the structure of the component logic and component.
- A GUI for configuring an instance of the component in SOPC Builder.
- Scripts and other information SOPC Builder needs to generate the hardware description language (HDL) files for the component and integrate the component instance into the system module.
- Other component-related information, such as reference to software drivers, necessary for development steps downstream of SOPC Builder.

This chapter discusses the design flow for new and legacy custom-defined SOPC Builder components, in the following sections:

- [“Component Providers” on page 4-2](#)
- [“Component Hardware Structure” on page 4-2](#)
- [“List of Available Components in SOPC Builder” on page 4-4](#)
- [“Tcl Components” on page 4-5](#)

### New Component Structure in v7.1 of the Quartus II Software

Version 7.1 of the Quartus® II software provided a new mechanism for storing and finding component files located on your computer.

If you use components created with a previous version of the Quartus II software, read through this chapter to familiarize yourself with the differences. This document uses the term “legacy components” to refer to components created with a previous version of the Quartus II software.

Legacy components are compatible with newer versions of SOPC Builder, with the following caveats:

- Legacy components that use a **More Options** tab in SOPC Builder, such as complex IP components provided by third-party IP developers, cannot be instantiated or used in version 7.1 and beyond. If your component has a “bind” program, you cannot use the component.
- To edit a legacy component using the component editor in version 7.1 and beyond, you must first upgrade the component to the new component editor flow. The process is automatic. However, the result is not backward compatible with previous versions.

## Component Providers

SOPC Builder components can be installed on your computer by several possible providers, including the following:

- The Quartus II software, which includes SOPC Builder, can install components as part of the fundamental functionality of the software.
- The Altera® MegaCore IP Library provides several intellectual property (IP) design blocks that are SOPC Builder ready.
- Third-party IP developers can provide IP blocks as SOPC Builder ready components, including software drivers and documentation.
- Altera development kits, such as the Nios® II Development Kit, can provide SOPC Builder components as features.
- The SOPC Builder component editor can turn your own HDL files into custom components.

## Component Hardware Structure

There are two types of components, based on where the associated component logic resides:

- Components that include their associated logic inside the system module
- Components that interface to logic outside the system module

Figure 4–1 shows an example of both types of components.

**Figure 4–1. Component Logic Inside and Outside the System Module**

### Components That Include Logic Inside the System Module

For components that include logic inside the system module, the component provides a full description of its hardware by specifying an HDL file. During system generation, SOPC Builder instantiates the component in the system and connects it to the rest of the system. The component can include export signals, which become ports on the system itself, so that you can manually connect them to logic outside the system module.

In general, components connect to the system interconnect fabric using either the Avalon<sup>®</sup> Memory-Mapped (Avalon-MM) interface or the Avalon Streaming (Avalon-ST) interface. A single component can provide more than one Avalon port. For example, a component might provide an Avalon-ST source port for high-throughput data, in addition to an Avalon-MM slave port for control.

## Components That Interface to Logic Outside the System Module

For components that interface to logic outside the system module, the component files describe only the interface to the external logic. During system generation, SOPC Builder only exports an interface for the component to the top-level system module. You must manually connect the interface to the component outside the system.

### List of Available Components in SOPC Builder

Each time SOPC Builder starts, it searches for component files. The components that SOPC Builder finds are displayed in the list of available components on the SOPC Builder **System Contents** tab. There are several mechanisms that SOPC Builder uses to populate the list of available components:

- SOPC Builder automatically searches the **/ip** subdirectory of your Quartus II project directory. Adding a component to a project is as easy as copying it to a subdirectory here. This mechanism is recommended for all project-specific components.
- SOPC Builder searches all of the paths entered in **SOPC Builder/Tools/Options/IP Search Path** to support a global library of components. This mechanism is recommended for all global components.
- Quartus II project directory and user library paths—SOPC Builder identifies component files stored in the current Quartus II project directory and user library paths.
- Legacy component search paths—SOPC Builder searches the paths where previous versions of SOPC Builder expected to find component files.

The rest of this section focuses on Tcl components.

## Tcl Components

Tcl components are components where interaction with SOPC Builder is defined with a simple text file written in the Tcl scripting language. This section describes the structure of Tcl components and how they are stored.

For details on the SOPC Builder component editor, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

### Component Description File (`_hw.tcl`)

At a minimum, a Tcl component consists of the following files:

- A Verilog, HDL, or VHDL file that defines the top-level module of the custom component (optional).
- A component description file, which is a Tcl file with file name of the form `<entity name>_hw.tcl`.

The `_hw.tcl` file defines everything that SOPC Builder requires about the name and location of component design files.

The SOPC component editor can generate components without Verilog HDL or VHDL files.

### Component File Organization

A typical component uses the following directory structure. The names of the directories are not significant.

- `component_library/`
  - `hdl/`—a directory that contains the component HDL design files and the `_hw.tcl` file
    - `<component name>_hw.tcl`—the component description file
    - `<component name>.v` or `.vhd`—the HDL file that contains the top-level module
  - There is no expectation of an HDL folder, even for components that are created with the component editor. If you want to bundle your component in a directory, the basic structure is as follows:
    - `component_dir/`
    - `<name>_hw.tcl`
    - `<name>.v` or `.vhd`
    - `<name>_sw.tcl`
- `software/`—a directory that contains software drivers or libraries related to the component, if any

The component directory will often include a `_sw.tcl` file and the software definitions and drivers it refers to. Refer to the component software specification for further details.

### Introduction

This chapter describes the SOPC Builder component editor. The component editor provides a GUI to support the creation and editing of the `_hw.tcl` file that describes a component to SOPC Builder. You use the component editor to do the following:

- Specify a hardware description language (HDL) file that describes the modules that compose your component hardware.
- Define the interfaces on the component and provide information about how the interface functions.
- Specify the hardware interface or interfaces to the component, and define the behavior of each interface signal. Assign module signals to interfaces and determine signal roles.
- Specify relationships between interfaces, such as determining which clock interface is used by a slave interface.
- Declare any parameters that alter the component structure or functionality, and define a user interface to let users parameterize instances of the component.

For information on the use of the component editor, see the following sections:

- To start the component editor, refer to [“Starting the Component Editor” on page 5-2](#).
- For information about specifying HDL files that describe a component, refer to [“HDL Files Tab” on page 5-2](#).
- For information about specifying interface signals, refer to [“Signals Tab” on page 5-3](#).
- For information about specifying the Avalon-MM type of interface signals, refer to [“Interfaces Tab” on page 5-6](#).
- For information about specifying parameters, refer to [“Component Wizard Tab” on page 5-6](#).
- To save a component, refer to [“Saving a Component” on page 5-7](#).
- For information about changing a component after it has been saved, refer to [“Editing a Component” on page 5-8](#).

For more information about components, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*. For more information about the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification*.

## Component Hardware Structure

The component editor creates components with the following hardware characteristics:

- A component has one or more interfaces. Typically, an *interface* means an Avalon-MM master port or slave port. The component editor lets you build a component with any combination of Avalon-MM master or slave ports. You can also specify component signals that must appear at the top-level of the SOPC Builder system module, which you can manually connect to the logic outside the system module. Interfaces include:
  - Avalon-MM master/slave
  - Avalon Streaming source/sink
  - Interrupt sender/receiver
  - Clock input and output
  - Nios II Custom Instruction Conduit (for export only)
- Each interface is comprised of one or more signals.
- The component can represent a component that is instantiated inside the SOPC Builder system, and can represent a component outside the system with an interface to it on the generated system.

## Starting the Component Editor

To start the component editor in SOPC Builder, on the File menu, click **New Component**. When the component editor starts, the **Introduction** tab displays, which describes how to use the component editor.

The component editor presents several tabs that group related settings. A message window at the bottom of the component editor displays warning and error messages.

Each tab in the component editor provides on-screen information that describes how to use the tab. Click the triangle labeled **About** at the top-left of each tab to view these instructions. You can also refer to Quartus® II Online Help for additional information about the component editor.

You navigate through the tabs from left to right as you progress through the component creation process.

## HDL Files Tab

The first row of the table on the **HDL Files** tab must include the file with the top-level module and must specify all the HDL files. You use the **HDL Files** tab to specify an existing Verilog HDL, or VHDL file that describes the interface to the component hardware. If your component is an interface to external logic, then do not specify an HDL file.

You can also use the component editor to define logic interfaces to external logic. In this case, you do not provide HDL files, and instead you use the component editor to manually define the hardware interface.

After you specify an HDL file, the component editor immediately analyzes the file by invoking the Quartus II Analysis and Elaboration module. The component editor analyzes signals and parameters declared for all modules in the specified files. If the file is successfully analyzed, the component editor's **Signals** tab lists all design modules in the **Top Level Module** list. If your HDL contains more than one module, you must select the appropriate top-level module from the **Top Level Module** list.

If your design requires extra simulation files, you can specify them in the **Simulation Files** table. All files used in the simulation must be specified, even those already included for synthesis. SOPC Builder includes these files in the system test bench so they can provide special functionality during simulation. The simulation files do not affect the generated system hardware.

When the top-level module is changed, the component editor performs best-effort signal matching against the existing port definitions. If a port is absent from the module, it is removed from the port list.

## Signals Tab

You use the **Signals** tab to specify the purpose of each signal on the top-level component module. If you specified a file on the **HDL Files** tab, the signals on the top-level module appear on the **Signals** tab.

If the component is an interface to external logic, you must manually add the signals that comprise the interface to the external logic. The **Interface** list also allows creation of a new interface.

Each signal must belong to an interface and be assigned a signal type. The signal type for new signals that have not been assigned a signal type is `Export`, which means that SOPC Builder does not connect the signal internally to the system module, and instead exposes the signal on the top-level system module.

You assign each signal to an interface using the **Interface** list. In addition to Avalon Memory-Mapped and Streaming interfaces, components typically have a conduit interface for exported signals.

## Naming Signals for Automatic Type and Interface Recognition

The component editor recognizes signal types and interfaces based on the names of signals in the source HDL file, if they follow naming conventions. [Table 5-1](#) lists the signal naming conventions.

Type of Signal	Name Convention
Signal associated with a specific interface	<code>&lt;interface type&gt;_&lt;interface name&gt;_&lt;signal type&gt;[_n]</code>

For any value of Interface Name the component editor automatically creates an interface by that name, if necessary, and assigns the signal to it. The *Signal Type* must match one of the valid signal types for the type of interface. You can append `_n` to indicate an active-low signal. [Table 5-2](#) lists the valid values for Interface Type.

Value	Meaning
avs	Avalon-MM slave
avm	Avalon-MM master
ats	Avalon-MM tristate slave
atm	Avalon-MM Tristate Master
aso	Avalon-ST Source
asi	Avalon-ST Sink
cso	Clock Output
csi	Clock Input
inr	Interrupt Receiver
ins	Interrupt Sender
cos	Conduit Start
coe	Conduit End
ncm	Nios II Custom Instruction Master
ncs	Nios II Custom Instruction Slave
csi_clockreset_clk	Clock Reset
csi_clockreset_reset_n	Clock Reset N

[Example 5-1](#) shows a Verilog HDL module declaration with signal names that infer two Avalon-MM slave ports.

---

**Example 5–1. Verilog Module With Automatically Recognized Signal Names**

```
module my_multiport_component (
    // Signals for Avalon-MM slave port "s1"
    avs_s1_clk,
    avs_s1_reset_n,
    avs_s1_address,
    avs_s1_read,
    avs_s1_write,
    avs_s1_writedata,
    avs_s1_readdata,
    avs_s1_export_dac_output,

    // Signals for Avalon-MM slave port "s2"
    avs_s2_address,
    avs_s2_read,
    avs_s2_readdata,
    avs_s2_export_dac_output,

    // Clock/Reset Interface csi_clockreset_clk
);
```

---

### Templates for Interfaces to External Logic

If you are creating an interface to external logic, you can use the Templates menu in the component editor to add a set of signals, such as the following:

- Avalon-MM Slave
- Avalon-MM Slave with Interrupt
- Avalon-MM Master
- Avalon-MM Master with Interrupt
- Avalon-ST Source
- Avalon-ST Sink

After adding a template, you can add or delete signals to customize the interface to meet your needs.

## Interfaces Tab

The **Interfaces** tab allows you to configure the interfaces on your component, and specify a name for each interface. The interface name identifies the interface, and also appears in the SOPC Builder connection panel. The interface name is also used to uniquely identify any signals that are exposed on the top-level system module.

The **Interfaces** tab also allows you to configure the type and properties of each interface. For example, an Avalon-MM slave interface has timing parameters which you must set appropriately.

If you convert an older Avalon-MM slave to the new model, you may require three interfaces: a clock input, the Avalon slave, and an interrupt sender. A parameter in the interrupt sender must be set to reference the Avalon slave.

## Component Wizard Tab

The **Component Wizard** tab provides options that affect the presentation of your new component.

### Identifying Information

You can specify information that identifies the component as follows:

- **Folder**—Specifies the location of the component, determined by the location of the top-level HDL file.
- **Component Display Name**—Specifies the internal name of the component. The internal name is used when saving a system containing an instance of this component, and is the name use for the component type when you create a system using a script..
- **Component Version**—Specifies which version of the component you are using.
- **Component Group**—Specifies which group in SOPC Builder displays your component in the list of available components. If you enter a previously unused group name, SOPC Builder creates a new group by that name.
- **Description**—Allows you to describe the component (optional).
- **Created By**—Allows you to specify the author of the component (optional).
- **Icon**—Allows you to associate the component with a file path relative to the component. The icon can be a **.jpg**, **.gif**, or **.png** file (optional).
- **Parameters**—Allows you to specify the parameters for creating the component. See further description below.

The component editor assigns the class name to be the same name as the top-level HDL module. The class name is the name SOPC Builder uses to identify the component.

## Parameters

The **Parameters** table allows you to specify the user-configurable parameters for the component.

If the top-level module of the component HDL declares any parameters (*parameters* for Verilog, HDL, or *generics* for VHDL), those parameters appear in the **Parameters** table. These parameters are presented to you when you create or edit an instance of your component. Using the **Parameters** table, you can specify whether or not each parameter is user-editable.

The following rules apply to HDL parameters exposed via the component GUI:

- Editable parameters cannot contain computed expressions.
- If a parameter  $N$  defines the width of a signal, the signal width must be of the form  $N-1..0$ .
- When a VHDL component is used in a Verilog HDL system module, or vice versa, numeric parameters must be 32-bit decimal integers. Passing other numeric parameter types might fail.

Click **Preview the Wizard** at any time to see how the component GUI will appear.

## Saving a Component

You can save the component by clicking **Finish** on any of the tabs, or by clicking **Save** on the File menu. Based on the settings you specify in the component editor, the component editor creates a component description file with the file name *<name of top-level module>\_hw.tcl*. The component editor saves the file in the same directory as the HDL file that describes the component's hardware interface. If you did not specify an HDL file, you can save the component description file to any location you choose.

You can relocate component files later. For example, you could move component files into a subdirectory and store it in a central network location so that other users can instantiate the component in their systems.

# Editing a Component

After you save a component and exit the component editor, you can edit it in SOPC Builder. To edit a component, right-click it in the list of available components on the **System Contents** tab and click **Edit Component**.

You cannot edit components that were created outside of the component editor, such as Altera®-provided components.

If you edit the HDL for a component and change the interface to the top-level module, you need to edit the component with the component editor to reflect the changes you made to the HDL.

This chapter describes the Tcl scripting commands that you can use to define custom components for use in an SOPC Builder system. You can also use the scripting interface to declare and set parameter values for your components.

The Tcl scripting commands provide a programmatic interface that you might prefer to the graphical user interface (GUI) of the component editor. If you need to make global updates to multiple components, Tcl scripts allow you to make the changes without accessing each component through the GUI.

You can use the Tcl scripting commands or the component editor to create a component description file with the file name *<name of top-level module>\_hw.tcl*. This file is stored in the same directory as the HDL file that provides the top-level description of the component. You can edit this file using the text editor of your choice.

You can download sample \*\_hw.tcl files from the Altera website by clicking the Design Example hyperlink located under this chapter, *Building a Component Interface with Tcl Scripting Commands*.

The remainder of this chapter describes the commands and properties you can use to describe components, component interfaces and parameters. These include:

- “Organization of a Component Tcl File” on page 6-2
- “Set and Add Commands” on page 6-3
- “Module Properties” on page 6-4
- “Clock Interface” on page 6-4
- “Avalon-MM Master Interface” on page 6-5
- “Avalon-MM Slave Interface” on page 6-5
- “Avalon-MM Tristate Interface” on page 6-7
- “Nios II Custom Instruction Interface” on page 6-8
- “Interrupt Interface” on page 6-9
- “Conduit Interface” on page 6-10

## Organization of a Component Tcl File

The following steps describe how to organize a component Tcl file.

1. Start the component definition with the `set_source` command, followed by the `set_module` command. The name of the module must match the component's top-level Verilog or VHDL entity name.

---

### Example 6–1. Example of Set Module Command

```
set_module "my_module"
```

---

2. Define the module properties, which are pieces of static information about a module. The following example illustrates some of the `set` command and `module` properties. See [Table 6–5](#).

---

### Example 6–2. The Set Command and Module Properties

```
set_source_file "./my_component.v"
set_module_description "My Component"
set_module_property version "1.0"
set_module_property group "My Components"
set_module_property simulationFiles [ list "./my_component.v" ]
```

---

3. Define the module parameters, which are settings that the user of the component makes when parameterizing it. The following example illustrates how to define module parameters.

---

### Example 6–3. Example of Parameters

```
# Module parameters
add_parameter "DWIDTH" "integer" "32" ""
add_parameter "AWIDTH" "integer" "32" ""
```

---

4. Add interfaces. For each interface, first add the interface, then set its properties and define its ports. Refer to the Avalon-MM specification for port types. The following example defines an Avalon-MM slave interface using only the required properties.

---

### Example 6–4. Avalon-MM Slave Interface

```
# Interface my_slave
# all interfaces must specify an associated clock interface
add_interface "my_slave" "avalon" "slave" "my_clock_interface"

set_interface_property "my_slave" "timingUnits" "cycles"
```

```

set_interface_property "my_slave" "writeWaitTime" "0"
set_interface_property "my_slave" "readLatency" "0"
set_interface_property "my_slave" "holdTime" "0"
set_interface_property "my_slave" "readWaitTime" "0"
set_interface_property "my_slave" "setupTime" "0"

# Ports in interface my_slave
add_port_to_interface "my_slave" "my_slave_write" "write"
add_port_to_interface "my_slave" "my_slave_writedata" "writedata"
add_port_to_interface "my_slave" "my_slave_waitrequest" "waitrequest"

```

## Set and Add Commands

The set and add commands establish basic information about a component.

**Table 6–1. Set and Add Commands**

Command	Arguments
set_module	<name of the module> (1)
set_source_file	<path to HDL file> (2)
set_module_description	<description of the module>
set_module_property	<name of property> <value of property>
add_interface	<name of interface> <type of interface> <direction> <associated clock> (3)
set_interface_property	<name of interface> <name of property> <value of property>
add_port_to_interface	<name of interface> <port name> <type of port>
set_port_direction_and_width	<name of port> <direction> <width>

**Notes to Table 6–1:**

- (1) Declares a new module. Must match the top-level Verilog HDL module or VHDL entity.
- (2) If the component is not based on HDL, set\_source\_file should be used with an empty string, such as "set\_source\_file".
- (3) This command is only required when a source file is not set. If a source file is set, the Quartus II software analyzes the file and determines the port widths and directions.

## Module Properties

The module properties are the arguments to the `set_module_property` command. Table 6–2 lists the module properties.

Name	Legal Values	Description
<code>version</code>	dotted integers	A version string, for example: 1.2.3
<code>group</code>	string	A string that represents the category under which the component should be listed.
<code>simulationFiles</code>	list of strings	The name of HDL files for use in simulation. This parameter is required even if the same file is used for synthesis and simulation. All files required for simulation must be specified, not just the top-level file.
<code>synthesisFiles</code>	list of strings	The name of HDL files for use in synthesis.
<code>author</code>	string	Name of the component author.
<code>iconPath</code>	string	Path to an image file, which contains an icon to show in the default editor. When referring to local files, they are relative to the Tcl File (.tcl).
<code>datasheetURL</code>	string	URL pointing to the component datasheet. Can be local or on a network. When referring to local files, they are relative to the TCL file.

## Clock Interface

There are no special properties for clock interfaces. A clock interface should not specify an associated clock interface. Clock interface directions are “source” and “input”. The following example defines a clock interface.

### Example 6–5. Clock Interface

```
# Clock Interface <my_clk_interface>
add_interface "my_clk_interface" "clock" "input"
set_interface_property "clock" "externallyDriven" "false"
set_interface_property "clock" "clockRateKnown" "false"
set_interface_property "clock" "clockRate" "0"
# Ports in interface clock
add_port_to_interface "clock" "clk" "clk"
add_port_to_interface "clock" "reset_n" "reset_n"
```

## Avalon-MM Master Interface

Table 6–3 describes the properties that characterize an Avalon-MM master interface. The direction of an Avalon-MM master interface is “master”.

**Table 6–3. Avalon-MM Master Interface Properties**

Name	Default Value	Legal Values	Description
doStreamReads	false	(true,false)	Specifies whether the master supports Avalon flow control read accesses. (This property is optional).
doStreamWrites	false	(true,false)	Specifies whether the master supports Avalon flow control write accesses. (This property is optional).—
burstOnBurstBoundaries Only	false	(true,false)	If true, bursts are aligned on burst size. (This property is optional.)

## Avalon-MM Slave Interface

Table 6–4 describes the properties that characterize an Avalon-MM slave interface. The direction of an Avalon-MM slave interface is “slave”.

**Table 6–4. Avalon-MM Slave Interface Properties (Part 1 of 2)**

Name	Default Value	Legal Values	Description
readLatency	0	[0 - 63]	Read latency for fixed-latent slaves.
timingUnits	cycles	(cycles, nanoseconds)	Specifies the unit for writeWaitTime, readWaitTime.
writeWaitTime	0	[1000 - 0]	Specifies additional time in units of timeUnits for write to be asserted.
holdTime	0	-	Specifies time in timeUnits between deassertion of read/write and deassertion of chipselect, address and data.
readWaitTime	1	[1000 - 0]	Specifies additional time in units of timeUnits for read to be asserted.
setUpTime	0	[1000 - 0]	Specifies time in timeUnits between assertion of chipselect, address and data and assertion of read/write.
maximumPendingReadTransactions	0	position	The maximum number of pending read accesses which can be queued up by the slave.
burstOnBurstBoundaries Only	false	(true,false)	If true, bursts are aligned on burst size.

**Table 6–4. Avalon-MM Slave Interface Properties (Part 2 of 2)**

Name	Default Value	Legal Values	Description
<code>isNonVolatileStorage</code>	false	(true,false)	For software environment purposes. Indicates if the memory is a non-volatile storage device.
<code>printableDevice</code>	false	(true,false)	For software environment purposes. Indicates if the memory is a non-volatile storage device.
<code>isMemoryDevice</code>	false	(true,false)	For software environment purposes. States that the slave is a reasonable target for code and data.

## Avalon-ST Source Interface

Table 6–5 lists the properties that characterize an Avalon-ST source interface. Refer to the Avalon-ST specification for port types. The direction of an Avalon-ST source interface is “source”.

**Table 6–5. Avalon-ST Source Interface Properties**

Name	Default Value	Legal Values	Description
<code>symbolsPerBeat</code>	1	[1-512]	The number of symbols that are transferred on every valid cycle.
<code>dataBitsPerSymbol</code>	8	[1-512]	Defines the number of bits per symbol. Most interfaces are byte-oriented so that a symbol is 8 bits.
<code>readyLatency</code>	0	[8-0]	Defines the relationship between assertion/deassertion of the <code>ready</code> signal, and cycles which are considered to be <code>ready</code> for data transfer, separately for each interface.
<code>maxChannel</code>	0	[low-high]	The maximum number of channels that a data interface can support.

## Avalon-ST Sink Interface

Table 6–6 lists the properties that characterize an Avalon-ST sink interface. Refer to the Avalon-ST specification for port types. The direction of an Avalon-ST sink interface is “sink”.

**Table 6–6. Avalon-ST Sink Interface Properties**

Name	Default Value	Legal Values	Description
<code>symbolsPerBeat</code>	1	[512-1]	The number of symbols that are transferred on every valid cycle.
<code>dataBitsPerSymbol</code>	8	[512-1]	Defines the number of bits per symbol. Most interfaces are byte-oriented so that a symbol is 8 bits.
<code>readyLatency</code>	0	[8-0]	Defines the relationship between assertion/deassertion of the <code>ready</code> signal, and cycles which are considered to be ready for data transfer, separately for each interface.
<code>maxChannel</code>	0	[255-0]	The maximum number of channels that a data interface can support.

## Avalon-MM Tristate Interface

Table 6–7 lists the properties that characterize an Avalon-MM tristate interface. The Avalon-MM tristate interface properties include all the properties that define the Avalon-MM slave interface, plus two additional properties: `activeCSThroughReadLatency` and `maximumPendingReadTransactions`.

Note that `maximumPendingReadTransactions` is not tristate specific. This property can also be assigned to an Avalon State.

The direction of an Avalon-MM tristate interface is “slave”.

**Table 6–7. Avalon-MM Tristate Interface Properties (Part 1 of 2)**

Name	Default Value	Legal Values	Description
<code>readLatency</code>	0	<code>num_cycles</code>	Read latency for fixed-latency slaves.
<code>writeLatency</code>	0	<code>num_cycles</code>	Delay in cycles between acceptance of a write access and acceptance of valid <code>writedata</code> .
<code>timingUnits</code>	<code>cycles</code>	( <code>cycles</code> , <code>nanoseconds</code> )	Specifies the unit for <code>writeWaitTime</code> and <code>readWaitTime</code> .
<code>writeWaitTime</code>	0	[1000-0]	Specifies additional time in units of <code>timeUnits</code> for write to be asserted.

**Table 6–7. Avalon-MM Tristate Interface Properties (Part 2 of 2)**

Name	Default Value	Legal Values	Description
holdTime	0	—	Specifies time in <code>timeUnits</code> between deassertion of <code>read/write</code> and deassertion of <code>chipselct</code> , <code>address</code> and <code>data</code> .
readWaitTime	1	[1000-0]	Specifies additional time in units of <code>timeUnits</code> for read to be asserted.
setupTime	0	—	Specifies time in <code>timeUnits</code> between assertion of <code>chipselct</code> , <code>address</code> , and <code>data</code> and assertion of <code>read/write</code> .
activeCSThroughRead Latency	false	(true,false)	If true, assert <code>chipselct</code> while <code>readdata</code> is pending.
maximumPendingRead Transactions	false	—	States the maximum number of pending read transactions.
minimumUninterrupted RunLength	1	an integer	Specifies a minimum arbitration share value.
isNonVolatileStorage	false	(true,false)	For software environment purposes. True for flash memories.
printableDevice	false	(true,false)	For software environment purposes. States that the slave is a reasonable sink for <code>printf()</code> data.
isMemoryDevice	false	(true,false)	For software environment purposes. States that the slave is a reasonable target for code and data.

## Nios II Custom Instruction Interface

Table 6–8 lists all the properties that characterize Nios II custom instructions.

**Table 6–8. Nios II Custom Instruction Interface**

Name	Default Value	Legal Values	Description
operands	0	[2-0]	Number of operands used by the custom instruction module.
clockCycle	0	—	Number of clock cycles the custom instruction requires before a valid result is returned—used by multicycle custom instructions.

The following example illustrates all the properties for a custom instruction.

**Example 6–6. Custom Instruction Example**

```

set_source_file "custominstruction.v"
set_module "custominstruction"
set_module_description "A custom instruction"
set_module_property version "1.0"
set_module_property group "User Logic"

# Module parameters
# Interface nios_custom_instruction_slave_0
add_interface "nios_custom_instruction_slave_0" "nios_custom_instruction" "slave"
"asynchronous"
set_interface_property "nios_custom_instruction_slave_0" "operands" "2"
set_interface_property "nios_custom_instruction_slave_0" "clockCycle" "2"

# Ports in interface nios_custom_instruction_slave_0
add_port_to_interface "nios_custom_instruction_slave_0" "clk" "clk"
add_port_to_interface "nios_custom_instruction_slave_0" "reset" "reset"
add_port_to_interface "nios_custom_instruction_slave_0" "clk_en" "clk_en"
add_port_to_interface "nios_custom_instruction_slave_0" "start" "start"
add_port_to_interface "nios_custom_instruction_slave_0" "n" "n"
add_port_to_interface "nios_custom_instruction_slave_0" "dataaa" "dataaa"
add_port_to_interface "nios_custom_instruction_slave_0" "datab" "datab"
add_port_to_interface "nios_custom_instruction_slave_0" "a" "a"
add_port_to_interface "nios_custom_instruction_slave_0" "b" "b"
add_port_to_interface "nios_custom_instruction_slave_0" "c" "c"
add_port_to_interface "nios_custom_instruction_slave_0" "readra" "readra"
add_port_to_interface "nios_custom_instruction_slave_0" "readrb" "readrb"
add_port_to_interface "nios_custom_instruction_slave_0" "writerc" "writerc"
add_port_to_interface "nios_custom_instruction_slave_0" "result" "result"
add_port_to_interface "nios_custom_instruction_slave_0" "done" "done"

```

**Interrupt Interface**

Slave components in an SOPC Builder system typically generate interrupts. A processor typically clears the interrupt bits in the slave's control and status registers after servicing the interrupt. [Table 6–9](#) lists the properties that characterize interrupts. The direction of an interrupt interface is “sender” and “receiver”.

**Table 6–9. Interrupt Interface Properties**

Name	Default Value	Legal Values	Description
associatedAddressablePoint	—	an interface name	This parameter takes the name of the component interface that provides access to the registers that should be cleared after the interrupt is serviced.

The following example defines an interrupt interface.

**Example 6–7. Interrupt Interface**

```
# IRQ Interface my_slave_irq
# legal values for the third parameter <direction> are sender and receiver
add_interface my_slave_irq "interrupt" "sender" "global_signals_clock"

set_interface_property "my_slave_irq" "associatedAddressablePoint" "my_slave"

# Ports in interface my_slave_irq
# Generally there is only one signal of type interrupt
add_port_to_interface "my_slave_irq" "my_irq" "irq"
```

---

## Conduit Interface

A conduit interface is used to export arbitrary input and output signals outside of an SOPC Builder system. There are no special properties associated with conduit interfaces.

The following example illustrates the conduit interface.

**Example 6–8. Conduit interface**

```
# Wire Interface global_signals_export
add_interface "global_signals_export" "conduit" "output" "my_clk_interface"

# Ports in interface global_signals_export
add_port_to_interface "global_signals_export" "prbs_test_error" "export"
add_port_to_interface "global_signals_export" "prbs_test_done" "export"
```

---

## Document Revision History

Table 6–10 shows the revision history for this chapter.

<i>Table 6–10. Document Revision History</i>		
Date and Document Version	Changes Made	Summary of Changes
October 2007, v7.2.0	Major reorganization of chapter to better reflect work flow when using tcl scripting. Includes new commands, properties, and parameters.	—
May 2007, v7.1.0	Initial release.	—

## Introduction

This chapter helps you identify the files you must include when archiving an SOPC Builder project. With this information, you can archive:

- The SOPC Builder system module
- The associated Nios<sup>®</sup> II software project, if any
- The associated Nios II system library project, if any

You may want to archive your SOPC Builder system for one of the following reasons:

- To place an SOPC Builder design under source control
- To create a backup
- To bundle a design for transfer to another location

To use this information, you must decide what source control or archiving tool to use, and you must know how to use it. This chapter does not provide step-by-step instructions. It does cover the following information:

- How to find and identify the files that you must include in an archived SOPC Builder design, refer to [“Required Files” on page 7-2.](#)
- Which files must have write permission to allow the design to be generated and the software projects compiled, refer to [“File Write Permissions” on page 7-4.](#)

## Scope

This chapter provides information about archiving SOPC Builder system modules, including their Nios II software applications, if any. If your SOPC Builder system does not contain a Nios II processor, you can disregard information about Nios II software applications.

This chapter does not cover archiving SOPC Builder components, for two reasons:

- SOPC Builder components can be recovered, if necessary, from the original Quartus<sup>®</sup> II and Nios II installations.
- If your SOPC Builder system was developed with an earlier version of the Quartus II software and Nios II Embedded Design Suite (EDS), when you restore it for use with the current version, you normally use the current, installed components.

If your SOPC Builder system was developed with an earlier version of the Quartus II and Nios II development software and you restore it for use with the current version, the regenerated system is functionally identical to the original system. However, there might be differences in details such as Quartus II timing, component implementation, or HAL implementation.

For details of version changes, refer to the release notes for the Quartus II software and the Nios II EDS.

To ensure that you can regenerate your exact original design, maintain a record of the tool and IP version(s) originally used to develop the design. Retain the original installation files or media in a safe place.

The archival process addressed by this chapter is different than Quartus II project archiving. A Quartus II project archive contains the complete Quartus II project, including the SOPC Builder module, but not including any Nios II software. Quartus II adds all HDL files to the archive, including HDL files generated by SOPC Builder, although these files are not strictly necessary.

This chapter is only concerned with archiving the SOPC Builder system, without the generated HDL files, but with all files needed to regenerate them and rebuild the Nios II software (if any).

For more details about archiving Quartus II projects, refer to volume 2 of the *Quartus II Handbook*.

## Required Files

This section describes the files required by an SOPC Builder system and its associated Nios II software projects (if any). This is the minimum set of files needed to completely recompile an archived system, both the SRAM Object File (**.sof**) and the executable software (**.elf**).

If you have Nios II software projects, archive them together with the SOPC Builder system on which they are based. You cannot rebuild a Nios II software project without its associated SOPC Builder system.

## SOPC Builder Design Files

The files listed in [Table 7-1](#) are located in the Quartus II project directory.

File description	File name	Write permission required? (1)
SOPC Builder system description	<socp_builder_system>.sopc	Yes
SOPC Builder legacy system description (2)	<socp_builder_system>.ptf	Yes
All non-generated HDL source files (3)	for example: <b>top_level_schematic.bdf,</b> <b>customlogic.v</b>	No
Quartus II project file	<project_name>.qpf	No
Quartus II settings file	<project_name>.qsf	No

### Notes to [Table 7-1](#):

- (1) For further information about write permissions, refer to “File Write Permissions” on page 7-4.
- (2) The <socp\_builder\_system>.ptf file is only required if you intend to edit or view the system in a version of SOPC Builder prior to version 7.1.
- (3) Include all HDL source files not generated by SOPC Builder. This includes HDL source files you create or copy from elsewhere. To identify a file generated by SOPC Builder, open the file and look for the following header:  
Legal Notice: (C)2007 Altera Corporation. All rights reserved.

## Nios II Application Software Project Files

The files listed in [Table 7-2](#) are located in the Nios II software project directory.

For more information about Nios II software projects, refer to the *Nios II Software Developer's Handbook*.

File Description	File Name	Write Permission Required? (1)
All source files	for example: <b>app.c, header.h,</b> <b>assembly.s, lookuptable.dat</b>	No
Eclipse project file	<b>.project</b>	No
C/C++ Development Toolkit project file	<b>.cdtproject</b>	Yes
C/C++ Development Toolkit option file	<b>.cdtbuild</b>	No
Software configuration file	<b>application.stf</b>	No

### Note to [Table 7-2](#):

- (1) For further information about write permissions, refer to “File Write Permissions” on page 7-4.

## Nios II System Library Project

The files listed in [Table 7-3](#) are located in the Nios II system library project directory.

For more information about Nios II system libraries, refer to the *Nios II Software Developer's Handbook*.

<b>Table 7-3. Files Required for a Nios II System Library Project</b>		
<b>File description</b>	<b>File name</b>	<b>Write permission required? (1)</b>
Eclipse project file	<b>.project</b>	Yes
C/C++ Development Toolkit project file	<b>.cdtproject</b>	Yes
C/C++ Development Toolkit option file	<b>.cdtbuild</b>	No
System software configuration file	<b>system.stf</b>	Yes

**Note to Table 7-3:**

(1) For further information about write permissions, see “File Write Permissions” on page 7-4.

Archiving for projects that use Tcl scripting and java to create a Board Support Package (BSP) is covered in chapter 3 of the *Nios II Software Developer's Handbook, Common BSP Tasks*.

## File Write Permissions

You must have write permission for certain files. The tools write to these files as part of the generation and compilation process. If the files are not writable, the toolchain fails.

Many source control tools mark local files read-only by default. In this case, you must override this behavior. You do not have to check the files out of source control unless you are modifying the SOPC Builder design or Nios II software project.

## Referenced Documents

This chapter references the following documents:

- [The Quartus II Handbook, Volume 2](#)
- [Nios II Software Developer's Handbook, Common BSP Tasks](#)

## Document Revision History

Table 7-4 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007, v7.2.0	<ul style="list-style-type: none"> <li>• No change from previous release.</li> </ul>	—
May 2007, v7.1.0	<ul style="list-style-type: none"> <li>• Chapter 7 was previously chapter 6</li> <li>• Added information about new <b>.sopc</b> file type to <a href="#">Table 7-1</a></li> <li>• Added information about legacy <b>.ptf</b> file type to <a href="#">Table 7-1</a></li> <li>• Added Referenced Documents section</li> <li>• Added reference to new Common BSP Tasks chapter for archiving of Tcl projects</li> </ul>	Updates to this chapter include replacing the legacy <b>.ptf</b> file type with the new <b>.sopc</b> file type.
March 2007, v7.0.0	<ul style="list-style-type: none"> <li>• No change from previous release</li> </ul>	—
November 2007, v6.1.0	<ul style="list-style-type: none"> <li>• No change from previous release</li> </ul>	—
May 2006, v6.0.0	Initial release.	—

This section provides instructions on how to use SOPC Builder to achieve specific goals. Chapters in this section serve to answer the question, "How do I use SOPC Builder?" Many chapters in this handbook provide design examples that you can download free from [www.altera.com](http://www.altera.com). Design file hyperlinks are located with individual chapters linked from the Altera web site.

This section includes the following chapters:

- [Chapter 8, Building Memory Subsystems Using SOPC Builder](#)
- [Chapter 9, Developing Components for SOPC Builder](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction

Most systems generated with SOPC Builder require memory. For example, embedded processor systems require memory for software code, while digital signal processing (DSP) systems require memory for data buffers. Many systems use multiple types of memories. For example, a processor-based DSP system can use off-chip SDRAM to store software code, and on-chip RAM for fast access to data buffers. You can use SOPC Builder to integrate almost any type of memory into your system.

This chapter describes how to build a memory subsystem as part of a larger system created with SOPC Builder. This chapter focuses on the following kinds of memory most commonly used in SOPC Builder systems for:

- “On-Chip RAM and ROM” on page 8–8
- “EPCS Serial Configuration Device” on page 8–12
- “SDRAM” on page 8–14
- “Off-Chip SRAM and Flash Memory” on page 8–19

This chapter assumes that you are familiar with the following:

- Creating FPGA designs and making pin assignments with the Quartus® II software. For details, refer to the *Introduction to the Quartus II Software* manual.
- Building simple systems with SOPC Builder. For details, refer to the *Introduction to SOPC Builder* in volume 4 of the *Quartus II Handbook*.
- SOPC Builder components. For details, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*.
- Basic concepts of the Avalon® interfaces. You do not need extensive knowledge of the Avalon interfaces, such as transfer types or signal timing. However, to create your own custom memory subsystem with external memories, you need to understand the Avalon® Memory-Mapped (Avalon-MM) interface. For details, refer to the *System Interconnect Fabric for Memory-Mapped Interfaces* chapter in volume 4 of the *Quartus II Handbook* and the *Avalon Memory-Mapped Interface Specification*.

## Example Design

This chapter demonstrates the process for building a system that contains one of each type memory as shown in [Figure 8-1](#). Each section of the chapter builds on previous sections, culminating in a complete system.

By following the example design in this chapter, you will learn how to create a complete customized memory subsystem for your system or design. The memory components in the example design are independent. For a custom system, you can instantiate exactly the memories you need, and skip the memories you do not need. Furthermore, you can create multiple instantiations of the same type of memory, limited only by on-chip memory resources or FPGA pins to interface with off-chip memory devices.

### *Example Design Structure*

[Figure 8-1](#) shows a block diagram of the example system.

Figure 8–1. Example Design Block Diagram

In Figure 8–1, all blocks shown below the system interconnect fabric comprise the memory subsystem. For demonstration purposes, this system uses a Nios® II processor core to master the memory devices, and a JTAG UART core to communicate with the processor. However, the memory subsystem could be connected to any master component, either on-chip or off-chip.

### Example Design Starting Point

The example design consists of the following elements:

- A Quartus II project named **quartus2\_project**. A Block Design File (.bdf) named **toplevel\_design**. **toplevel\_design** is the top-level design file for **quartus2\_project**. **toplevel\_design** instantiates the SOPC Builder system module, as well as other pins and modules required to complete the design.
- An SOPC Builder system named **sopc\_memory\_system**. **sopc\_memory\_system** is a subdesign of **toplevel\_design**. **sopc\_memory\_system** instantiates the memory components and other SOPC Builder components required for a functioning system module.

The starting point for this chapter assumes that the **quartus2\_project** already exists, **sopc\_memory\_system** has been started in SOPC Builder, and the Nios II core and the JTAG UART core are already instantiated. This example design uses the default settings for the Nios II/s core and the JTAG UART core; these settings do not affect the rest of the memory subsystem. [Figure 8-2](#) shows the starting point in the SOPC Builder.

**Figure 8-2. Starting Point for the Example Design**

All sections in this chapter build on this starting point.

## Hardware and Software Requirements

To build a memory subsystem similar to the example design in this chapter, you need the following:

- Quartus II Software version 5.0 or higher—Both Quartus II Web Edition and the fully licensed version support this design flow.
- Nios II Embedded Design Suite (EDS) version 5.0 or higher—Both the evaluation edition and the fully licensed version support this design flow. The Nios II EDS provides the SOPC Builder memory components described in this chapter. It also provides several complete example designs which demonstrate a variety of memory components instantiated in working systems.

The Quartus II Web Edition software and the Nios II EDS, Evaluation Edition are available free for download from the Altera® website. Visit [www.altera.com/download](http://www.altera.com/download).

This chapter does not describe downloading and verifying a working system in hardware. Therefore, there are no hardware requirements for the completion of this chapter. However, the example memory subsystem has been tested in hardware.

## Design Flow

This section describes the design flow for building memory subsystems with SOPC Builder.

The design flow for building a memory subsystem is similar to other SOPC Builder designs. After starting a Quartus II project and an SOPC Builder system, there are five steps to completing the system, as shown in [Figure 8-3](#):

1. Component-level design in SOPC Builder
2. SOPC Builder system-level design
3. Simulation
4. Quartus II project-level design
5. Board-level design

Figure 8–3. Design Flow

## Component-Level Design in SOPC Builder

In this step, you specify which memory components to use and configure each component to meet the needs of the system. All memory components are available from the **Memory and Memory Controllers** category in the SOPC Builder list of available components.

## SOPC Builder System-Level Design

In this step, you connect components together and configure the SOPC Builder system as a whole. Similar to the process of adding non-memory SOPC Builder components, you use the SOPC Builder **System Contents** tab to do the following:

- Rename the component instance (optional).
- Connect the memory component to master ports in the system. Each memory component must be connected to at least one master port.
- Assign a base address.
- Assign a clock domain. A memory component can operate on the same or different clock domain as the master port(s) that access it.

## Simulation

In this step, you verify the functionality of the SOPC Builder system module. For systems with memories, this step depends on simulation models for each of the memory components, in addition to the system test bench generated by SOPC Builder. Refer to “[Simulation Considerations](#)” for more information.

## Quartus II Project-Level Design

In this step, you integrate the SOPC Builder system module with the rest of the Quartus II project. This step includes wiring the system module to FPGA pins, and wiring the system module to other design blocks (such as other HDL modules) in the Quartus II project.

In the example design in this chapter, the SOPC Builder system module comprises the entire FPGA design. There are no other design blocks in the Quartus II project.

## Board-Level Design

In this step, you connect the physical FPGA pins to memory devices on the board. If the SOPC Builder system interfaces with off-chip memory devices, you must make board-level design choices.

## Simulation Considerations

SOPC Builder can automatically generate a test bench for register transfer level (RTL) simulation of the system. This test bench instantiates the system module and can also instantiate memory models for external memory components. The test bench is plain text HDL, located at the bottom of the top-level system module HDL design file. To explore the contents of the auto-generated test bench, open the top-level HDL file and search on keyword `test_bench`.

### *Generic Memory Models*

The memory components described in this chapter, except for the SRAM, provide generic simulation models. Therefore, it is very easy to simulate an SOPC Builder system with memory components immediately after generating the system.

The generic memory models store memory initialization files, such as Data [file name extension] (**.dat**) and Hexadecimal (**.hex**) files, in a directory named `<Quartus II project directory>/<SOPC Builder system`

*name>\_sim*. When generating a new system, SOPC Builder creates empty initialization files. You can manually edit these files to provide custom memory initialization contents for simulation.

For Nios II processor designs, the Nios II integrated development environment (IDE) generates initialization contents automatically.

### *Vendor-Specific Memory Models*

You can also manually connect vendor-specific memory models to the system module. In this case, you must manually edit the testbench and connect the vendor memory model. You might also need to edit the vendor memory model slightly for time delays. The SOPC Builder testbench assumes zero delay.

## On-Chip RAM and ROM

Altera FPGAs include on-chip memory blocks that can be used as RAM or ROM in SOPC Builder systems. On-chip memory has the following benefits for SOPC Builder systems:

- On-chip memory has fast access time, compared to off-chip memory.
- SOPC Builder automatically instantiates on-chip memory inside the system module, so you do not have to make any manual connections.
- Certain memory blocks can have initialized contents when the FPGA powers up. This feature is useful, for example, for storing data constants or processor boot code.

FPGAs have limited on-chip memory resources, which limits the maximum practical size of an on-chip memory to approximately one megabyte in the largest FPGA family.

### Component-Level Design for On-Chip Memory

In SOPC Builder you instantiate on-chip memory by clicking the **On-chip Memory (RAM or ROM)** in the component. The configuration wizard for the **On-chip Memory (RAM or ROM)** component has the following options: **Memory Type**, **Size**, and **Read Latency**.

#### *Memory Type*

The **Memory Type** options define the structure of the on-chip memory:

- **RAM (writable)**—This setting creates a readable and writable memory.
- **ROM (read only)**—This setting creates a read-only memory.

- **Dual-port access**—Turning on this setting creates a memory component with two slave ports, which allows two master ports to access the memory simultaneously.
- **Block type**—This setting directs the Quartus II software to use a specific type of memory block when fitting the on-chip memory in the FPGA. The following choices are available:
  - **Auto**—This setting allows the Quartus II software to choose the most appropriate memory resource.
  - **M512**—This setting directs the Quartus II software to use M512 blocks.
  - **M4K**—This setting directs the Quartus II software to use M4K blocks.
  - **M-RAM**—This setting directs the Quartus II software to use M-RAM blocks. The 64 Kbit M-RAM blocks are appropriate for larger RAM data buffers. However, M-RAM blocks do not allow pre-initialized contents at power up.

### *Size*

The **Size** options define the size and width of the memory.

- **Data width**—This setting determines the data width of the memory. The available choices are **8, 16, 32, 64, 128, 256, 512, or 1024** bits. Assign **Data width** to match the width of the master port that accesses this memory the most frequently or has the most critical timing requirements.
- **Total memory size**—This setting determines the total size of the on-chip memory block. The total memory size must be less than the available memory in the target FPGA.

### *Read Latency*

On-chip memory components use synchronous, pipelined Avalon-MM slave ports. Pipelined access improves  $f_{MAX}$  performance, but also adds latency cycles when reading the memory. The **Read latency** option allows you to specify the number of read latency cycles required to access data. If the **Dual-port access** setting is turned on, you can specify a different read latency for each slave port.

### *Non-Default Memory Initialization*

For ROM memories, you can specify your own initialization file by selecting **Enable non-default initialization file**. If this option is selected, the file you specify will be used to initialize the ROM in place of the default initialization file created by SOPC Builder.

### *Enable In-System Memory Content Editor Feature*

Allows you to enable the In-System Memory Content Editor, which allows you to read data from and write data to in-system memory in a device while the device is running at speed and independently of system clocks with a JTAG interface.

## **SOPC Builder System-Level Design for On-Chip Memory**

There are few SOPC Builder system-level design considerations for on-chip memories. See [“SOPC Builder System-Level Design” on page 8–6](#).

When generating a new system, SOPC Builder creates a blank initialization file in the Quartus II project directory for each on-chip memory that can power up with initialized contents. The name of this file is *<name of memory component>.hex*.

## **Simulation for On-Chip Memory**

At system generation time, SOPC Builder generates a simulation model for the on-chip memory. This model is embedded inside the system module, and there are no user-configurable options for the simulation testbench.

You can provide memory initialization contents for simulation in the file *<Quartus II project directory>/<SOPC Builder system name>\_sim/<Memory component name>.dat*.

## **Quartus II Project-Level Design for On-Chip Memory**

The on-chip memory is embedded inside the SOPC Builder system module, and therefore there are no signals to connect to the Quartus II project.

To provide memory initialization contents, you must fill in the file *<name of memory component>.hex*. The Quartus II software recognizes this file during design compilation and incorporates the contents into the configuration files for the FPGA.

For Nios II processor users, the Nios II integrated development environment (IDE) generates the memory initialization file automatically.

## Board-Level Design for On-Chip Memory

The on-chip memory is embedded inside the SOPC Builder system module, and therefore there is nothing to connect at the board level.

## Example Design with On-Chip Memory

This section demonstrates adding a 4 Kbyte on-chip RAM to the example design. This memory uses a single slave port with read latency of one cycle.

Figure 8–4 shows the SOPC Builder system after adding an instance of the on-chip memory component, renaming it to `onchip_ram`, and assigning it a base address.

**Figure 8–4. SOPC Builder System with On-Chip Memory**

Module Name	Description	Clock	Base	End	IRQ
<input type="checkbox"/> <b>cpu</b>	Nios II Processor - Altera C...	clk			
<input type="checkbox"/> instruction_master	Master port				
<input type="checkbox"/> data_master	Master port				
<input type="checkbox"/> jtag_debug_module	Slave port		0x00000000	0x000007FF	IRQ 0
<input type="checkbox"/> jtag_uart	JTAG UART	clk	0x00008000	0x0000807F	1
<input type="checkbox"/> <b>onchip_ram</b>	On-Chip Memory (RAM or R...	clk	0x00001000	0x00001FFF	

For demonstration purposes, Figure 8–5 shows the result of generating the system module at this stage. (In a normal design flow, you generate the system only after adding all system components.)

**Figure 8–5. System Module with On-Chip Memory**

Because the on-chip memory is contained entirely within the system module, `sopc_memory_system` has no I/O signals associated with `onchip_ram`. Therefore, you do not need to make any Quartus II project connections or assignments for the on-chip RAM, and there are no board-level considerations.

## EPCS Serial Configuration Device

Many systems use an Altera EPCS serial configuration device to configure the FPGA. Altera provides the EPCS device controller core, which allows SOPC Builder systems to access the memory contents of the EPCS device. This feature provides flexible design options:

- The FPGA design can reprogram its own configuration memory, providing a mechanism for in-field upgrades.
- The FPGA design can use leftover space in the EPCS as nonvolatile storage.

Physically, the EPCS device is a serial flash memory device, which has slow access time. Altera provides software drivers to control the EPCS core for the Nios II processor only. Therefore, EPCS controller core features are available only to SOPC Builder systems that include a Nios II processor.

For further details about the features and usage of the EPCS device controller core, refer to the *EPCS Device Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

### Component-Level Design for an EPCS Device

In SOPC Builder you instantiate an EPCS controller core by adding an **EPCS Serial Flash Controller** component. There are no settings for this component.

For details, refer to the *Nios II Flash Programmer User Guide*.

### SOPC Builder System-Level Design for an EPCS Device

There are not many SOPC Builder system-level design considerations for EPCS devices:

- Assign a base address.
- Set the IRQ connection to NC (disconnected). The EPCS controller hardware is capable of generating an IRQ. However, the Nios II driver software does not use this IRQ, and therefore you can leave the IRQ signal disconnected.

There can only be one EPCS controller core per FPGA, and the instance of the core is always named `epcs_controller`.

## Simulation for an EPCS Device

The EPCS controller core provides a limited simulation model:

- Functional simulation does not include the FPGA configuration process, and therefore the EPCS controller does not model the configuration features.
- The simulation model does not support read and write operations to the flash region of the EPCS device.
- A Nios II processor can boot from the EPCS device in simulation. However, the boot loader code is different during simulation. The EPCS controller boot loader code assumes that all other memory simulation models are pre-initialized, and therefore the boot load process is unnecessary. During simulation, the boot loader simply forces the Nios II processor to jump to start, skipping the boot load process.

Verification in the hardware is the best way to test features related to the EPCS device.

## Quartus II Project-Level Design for an EPCS Device

The Quartus II software automatically connects the EPCS controller core in the SOPC Builder system to the dedicated configuration pins on the FPGA. This connection is invisible to the user. Therefore, there are no EPCS-related signals to connect in the Quartus II project.

## Board-Level Design for an EPCS Device

You must connect the EPCS device to the FPGA as described in the *Altera Configuration Handbook*. No other connections are necessary.

## Example Design with an EPCS Device

This section demonstrates adding an EPCS device controller core to the example design.

**Figure 8–6** shows the SOPC Builder system after adding an instance of the EPCS controller core and assigning it a base address.

**Figure 8–6. SOPC Builder System with EPCS Device**

Module Name	Description	Clock	Base	End	IRQ
cpu	Nios II Processor - Altera C...	clk			
instruction_master	Master port				
data_master	Master port				
jtag_debug_module	Slave port				
jtag_uart	JTAG UART	clk	0x00000800	0x00000807	1
onchip_ram	On-Chip Memory (RAM or ...)	clk	0x00001000	0x00001FFF	
epcs_controller	EPCS Serial Flash Controller	clk	0x00002000	0x000027FF	10C
epcs_control_port	Slave port				

For demonstration purposes only, [Figure 8–7](#) shows the result of generating the system module at this stage.

**Figure 8–7. System Module with EPCS Device**

Because the Quartus II software automatically connects the EPCS controller core to the FPGA pins, the system module has no I/O signals associated with **epcs\_controller**. Therefore, you do not need to make any Quartus II project connections or assignments for the EPCS controller core.

This chapter does not cover the details of configuration using the EPCS device. For further information, refer to Altera’s *Configuration Handbook*.

## SDRAM

Altera provides a free SDRAM controller core, which allows you to use inexpensive SDRAM as bulk RAM in your FPGA designs. The SDRAM controller core is necessary, because Avalon-MM signals cannot describe the complex interface on an SDRAM device. The SDRAM controller acts as a bridge between the system interconnect fabric and the pins on an SDRAM device. The SDRAM controller can operate in excess of 100 MHz.

For further details about the features and usage of the SDRAM controller core, refer to the *SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

## Component-Level Design for SDRAM

The choice of SDRAM device(s) and the configuration of the device(s) on the board heavily influence the component-level design for the SDRAM controller. Typically, the component-level design task involves parameterizing the SDRAM controller core to match the SDRAM device(s) on the board. You must specify the structure (address width, data width, number of devices, number of banks, and so on) and the timing specifications of the device(s) on the board.

For complete details about configuration options for the SDRAM controller core, refer to the *SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

## SOPC Builder System-Level Design for SDRAM

In the SOPC Builder **System Contents** tab, the SDRAM controller looks like any other memory component. Similar to on-chip memory, there are few SOPC Builder system-level design considerations for SDRAM. See [“SOPC Builder System-Level Design” on page 8–6](#).

## Simulation for SDRAM

At system generation time, SOPC Builder can generate a generic SDRAM simulation model and include the model in the system testbench. To use the generic SDRAM simulation model, you must turn on a setting in the SDRAM controller configuration wizard. You can provide memory initialization contents for simulation in the file `<Quartus II project directory>/<SOPC Builder system name>_sim/<Memory component name>.dat`.

Alternately, you can provide a specific vendor memory model for the SDRAM. In this case, you must manually wire up the vendor memory model in the system testbench.

For further details, refer to [“Simulation Considerations” on page 8–7](#) and the *SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

## Quartus II Project-Level Design for SDRAM

SOPC Builder generates a system module with top-level I/O signals associated with the SDRAM controller. In the Quartus II project, you must connect these I/O signals to FPGA pins, which connect to the SDRAM device on the board. In addition, you might have to accommodate clock skew issues.

### *Connecting and Assigning the SDRAM-Related Pins*

After generating the system with SOPC Builder, you can find the names and directions of the I/O signals in the top-level HDL file for the SOPC Builder system module. The file has the name *<Quartus II project directory>/<SOPC Builder system name>.v* or *<Quartus II project directory>/<SOPC Builder system name>.vhd*. You must connect these signals in the top-level Quartus II design file.

You must assign a pin location for each I/O signal in the top-level Quartus II design to match the target board. Depending on the performance requirements for the design, you might have to assign FPGA pins carefully to achieve performance.

### *Accommodating Clock Skew*

As SDRAM frequency increases, so does the possibility that you must accommodate skew between the SDRAM clock and I/O signals. This issue affects all synchronous memory devices, including SDRAM. To accommodate clock skew, you can instantiate an *altpll* megafunction in the top-level Quartus II design to create a phase-locked loop (PLL) clock output. You use a phase-shifted PLL output to drive the SDRAM clock and reduce clock-skew issues. The exact settings for the *altpll* megafunction depend on your target hardware; you must experiment to tune the phase shift to match the board.

For details, refer to the *altpll Megafunction User Guide*.

## **Board-Level Design for SDRAM**

Memory requirements largely dictate the board-level configuration of the SDRAM device(s). The SDRAM controller core can accommodate various configurations of SDRAM on the board, including multiple banks and multiple devices.

For further details, refer to the *SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

## **Example Design with SDRAM**

This section demonstrates adding a 16-Mbyte SDRAM device to the example design. This SDRAM is a single device with 32-bit data. [Figure 8–8](#) shows the **SDRAM Controller** configuration wizard settings for the example design.

**Figure 8–8. SDRAM Controller Configuration Wizard**

Figure 8–9 shows the SOPC Builder system after adding an instance of the SDRAM controller, renaming it to **sdram**, and assigning it a base address.

**Figure 8–9. SOPC Builder System with SDRAM**

Module Name	Description	Clock	Base	End	IRQ
cpu	Nios II Processor - Altera Corp...	clk			
instruction_master	Master port				
data_master	Master port				
jtag_debug_module	Slave port				
jtag_uart	JTAG UART	clk	0x00000800	0x00000807	1
onchip_ram	On-Chip Memory (RAM or ROM)	clk	0x00001000	0x00001FFF	
epcs_controller	EPCS Serial Flash Controller	clk	0x00002000	0x000027FF	NC
sdram	SDRAM Controller	clk	0x01000000	0x01FFFFFF	
s1	Slave port				

For demonstration purposes, Figure 8–10 shows the result of generating the system module at this stage, and connecting it in **toplevel\_design.bdf**.

Figure 8–10. *toplevel\_design.bdf* with SDRAM

After generating the system, the top-level system module file `socp_memory_system.v` contains the list of SDRAM-related I/O signals which must be connected to FPGA pins:

```
output [ 11: 0] zs_addr_from_the_sdram;
output [  1: 0] zs_ba_from_the_sdram;
output      zs_cas_n_from_the_sdram;
output      zs_cke_from_the_sdram;
output      zs_cs_n_from_the_sdram;
inout [ 31: 0] zs_dq_to_and_from_the_sdram;
output [  3: 0] zs_dqm_from_the_sdram;
output      zs_ras_n_from_the_sdram;
output      zs_we_n_from_the_sdram;
```

As shown in Figure 8–10, `toplevel_design.bdf` uses an instance of `sdram_pll` to phase shift the SDRAM clock by -63 degrees. `toplevel_design.bdf` also uses a subsdesign `delay_reset_block` to insert a delay on the `reset_n` signal for the system module. This delay is necessary to allow the PLL output to stabilize before the SOPC Builder system begins operating.

Figure 8–11 shows pin assignments in the Quartus II Assignment Editor for some of the SDRAM pins. The correct pin assignments depend on the target board.

Figure 8–11. Pin Assignments for SDRAM

	To	Location	I/O Bank	I/O Standard	General Function	Special Function	Reserved
188	SDRAM_A[0]	PIN_AE4	7	LVTTTL	Column I/O

208	SDRAM_DQM[3]	PIN_AG10	7	LVTTTL	Column I/O	DQ53B	

## Off-Chip SRAM and Flash Memory

SOPC Builder systems can directly access many off-chip RAM and ROM devices, without a controller core to drive the off-chip memory. Avalon-MM signals can exactly describe the interfaces on many standard memories, such as SRAM and flash memory. In this case, I/O signals on the SOPC Builder system module can connect directly to the memory device.

While off-chip memory usually has slower access time than on-chip memory, off-chip memory provides the following benefits:

- Off-chip memory is less expensive than on-chip memory resources.
- The size of off-chip memory is bounded only by the 32-bit Avalon-MM address space.
- Off-chip ROM, such as flash memory, can be used for bulk storage of nonvolatile data.
- Multiple off-chip RAM and ROM memories can share address and data pins to conserve FPGA I/O resources.

Adding off-chip memories to an SOPC Builder system also requires the **Avalon-MM Tristate Bridge** component.

This section describes the process of adding off-chip flash memory and SRAM to an SOPC Builder system.

## Component-Level Design for SRAM and Flash Memory

There are several ways to instantiate an interface to an off-chip memory device:

- For common flash interface (CFI) flash memory devices, add the **Flash Memory (Common Flash Interface)** component in SOPC Builder.
- For Altera development boards, Altera provides SOPC Builder components that interface to the specific devices on each development board. For example, the Nios II EDS includes the components **Cypress CY7C1380C SSRAM** and **IDT71V416 SRAM**, which appear on Nios II development boards.
- For further details about the features and usage of the SSRAM controller core, refer to the *SDRAM Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.
- For further details about the features and usage of the SDRAM controller core, refer to the *Building Memory Subsystems Using SOPC Builder* chapter in volume 4 of the *Quartus II Handbook*.

These components make it easy for you to create memory systems targeting Altera development boards. However, these components target only the specific memory device on the board; they do not work for different devices.

- For general memory devices, RAM or ROM, you can create a custom interface to the device with the SOPC Builder component editor. Using the component editor, you define the I/O pins on the memory device and the timing requirements of the pins.

In all cases, you must also instantiate the **Avalon-MM Tristate Bridge** component. Multiple off-chip memories can connect to a single tristate bridge.

### *Avalon-MM Tristate Bridge*

A tristate bridge connects off-chip devices to on-chip system interconnect fabric. The tristate bridge creates I/O signals on the SOPC Builder system module, which you must connect to FPGA pins in the top-level Quartus II project. These pins represent the system interconnect fabric to off-chip devices.

The tristate bridge creates address and data pins which can be shared by multiple off-chip devices. This feature lets you conserve FPGA pins when connecting the FPGA to multiple devices with mutually exclusive access.

You must use a tristate bridge in either of the following cases:

- The off-chip device has bidirectional data pins.
- Multiple off-chip devices share the address and/or data buses.

In SOPC Builder, you instantiate a tristate bridge by instantiating the **Avalon-MM Tristate Bridge** component. The Avalon-MM Tristate Bridge configuration wizard has a single option: To register incoming (to the FPGA) signals or not.

- **Registered**—This setting adds registers to all FPGA input pins associated with the tristate bridge (outputs from the memory device).
- **Not Registered**—This setting does not add registers between the memory device output pins and the system interconnect fabric.

The Avalon-MM tristate bridge automatically adds registers to output signals from the tristate bridge to off-chip devices.

Registering the input and output signals shortens the register-to-register delay from the memory device to the FPGA, resulting in higher system  $f_{\text{MAX}}$  performance. However, in each direction, the registers add one additional cycle of latency for Avalon-MM master ports accessing memory connected to the tristate bridge. The registers do not affect the timing of the transfers from the perspective of the memory device.

For details about the Avalon-MM tristate interface, refer to the *Avalon Memory-Mapped Interface Specification*.

### *Flash Memory*

In SOPC Builder, you instantiate an interface to CFI flash memory by adding a **Flash Memory (Common Flash Interface)** component. If the flash memory is not CFI compliant, you must create a custom interface to the device with the SOPC Builder component editor.

The choice of flash device(s) and the configuration of the device(s) on the board heavily influence the component-level design for the flash memory configuration wizard. Typically, the component-level design task involves parameterizing the flash memory interface to match the device(s) on the board. Using the Flash Memory (Common Flash Interface) configuration wizard, you must specify the structure (address width and data width) and the timing specifications of the device(s) on the board.

For details about features and usage, refer to the *Common Flash Interface Controller Core with Avalon Interface* chapter in volume 5 of the *Quartus II Handbook*.

For an example of instantiating the Flash Memory (Common Flash Interface) component in an SOPC Builder system, see “[Example Design with SRAM and Flash Memory](#)” on page 8–25.

### SRAM

To instantiate an interface to off-chip RAM, perform the following steps:

1. Create a new component with the SOPC Builder component editor that defines the interface.
2. Instantiate the new interface component in the SOPC Builder system.

The choice of RAM device(s) and the configuration of the device(s) on the board determine how you create the interface component. The component-level design task involves entering parameters into the component editor to match the device(s) on the board.

For details about using the component editor, refer to the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

## SOPC Builder System-Level Design for SRAM and Flash Memory

In the SOPC Builder **System Contents** tab, the Avalon-MM tristate bridge has two ports:

- Avalon-MM slave port—This port faces the on-chip logic in the SOPC Builder system. You connect this slave port to on-chip master ports in the system.
- Avalon-MM tristate master port—This port faces the off-chip memory devices. You connect this master port to the Avalon-MM tristate slave ports on the interface components for off-chip memories.

You assign a clock to the Avalon-MM tristate bridge that determines the Avalon-MM clock cycle time for off-chip devices connected to the tristate bridge.

You must assign base addresses to each off-chip memory. The Avalon-MM tristate bridge does not have an address; it passes unmodified addresses from on-chip master ports to off-chip slave ports.

## Simulation for SRAM and Flash Memory

The SOPC Builder output for simulation depends on the type of memory component(s) in the system:

- **Flash Memory (Common Flash Interface) component**—This component provides a generic simulation model. You can provide memory initialization contents for simulation in the file *<Quartus II project directory>/<SOPC Builder system name>\_sim/<Flash memory component name>.dat*.
- **Custom memory interface created with the component editor**—In this case, you must manually connect the vendor simulation model to the system test bench. SOPC Builder does not automatically connect simulation models for custom memory components to the system module.
- **Altera-provided interfaces to memory devices**—Altera provides simulation models for these interface components. You can provide memory initialization contents for simulation in the file *<Quartus II project directory>/<SOPC Builder system name>\_sim/<Memory component name>.dat*. Alternately, you can provide a specific vendor simulation model for the memory. In this case, you must manually wire up the vendor memory model in the system test bench.

For further details, see [“Simulation Considerations”](#) on page 8–7.

## Quartus II Project-Level Design for SRAM and Flash Memory

SOPC Builder generates a system module with top-level I/O signals associated with the tristate bridge and the memory interface components. In the Quartus II project, you must connect the I/O signals to FPGA pins, which connect to the memory device(s) on the board.

After generating the system with SOPC Builder, you can find the names and directions of the I/O signals in the top-level HDL file for the SOPC Builder system module. The file has the name *<Quartus II project directory>/<SOPC Builder system name>.v* or *<Quartus II project directory>/<SOPC Builder system name>.vhd*. You must connect these signals in the top-level Quartus II design file.

You must assign a pin location for each I/O signal in the top-level Quartus II design to match the target board. Depending on the performance requirements for the design, you might have to assign FPGA pins carefully to achieve performance.

SOPC Builder inserts synthesis directives in the top-level system module HDL to assist the Quartus II fitter with signals that interface with off-chip devices. The following is an example:

```
reg [ 22: 0] tri_state_bridge_address /* synthesis
ALTERA_ATTRIBUTE = "FAST_OUTPUT_REGISTER=ON" */;
```

## Board-Level Design for SRAM and Flash Memory

Memory requirements largely dictate the board-level configuration of the SRAM and flash memory device(s). You can lay out memory devices in any configuration, as long as the resulting interface can be described with Avalon-MM signals.

Special consideration is required when connecting the Avalon-MM address signal to the address pins on the memory devices.

The system module presents the smallest number of address lines required to access the largest off-chip memory, which is usually less than 32 address bits. Not all memory devices connect to all address lines.

### *Aligning the Least-Significant Address Bits*

The Avalon-MM tristate address signal always presents a byte address. Each address location in many memory devices contains more than one byte of data. In this case, the memory device must ignore one or more of the least-significant Avalon-MM address lines. For example, a 16-bit memory device must ignore Avalon-MM address [0] (which is a byte address), and connect Avalon-MM address [1] to the least-significant address line.

Table 8–1 shows the relationship between Avalon-MM address lines and off-chip address pins for all possible Avalon-MM data widths.

**Table 8–1. Connecting the Least-Significant Avalon-MM Address Line**

Avalon-MM Address Line	Address Line on Memory Device				
	8-bit Memory	16-bit Memory	32-bit Memory	64-bit Memory	128-bit Memory
address [0]	A0	No connect	No connect	No connect	No connect
address [1]	A1	A0	No connect	No connect	No connect
address [2]	A2	A1	A0	No connect	No connect
address [3]	A3	A2	A1	A0	No connect
address [4]	A4	A3	A2	A1	A0
address [5]	A5	A4	A3	A2	A1
address [6]	A6	A5	A4	A3	A2
address [7]	A7	A6	A5	A4	A3
address [8]	A8	A7	A6	A5	A4
address [9]	A9	A8	A7	A6	A5
address [10]	A10	A9	A8	A7	A6
...	...	...	...	...	...

### *Aligning the Most-Significant Address Bits*

The Avalon-MM address signal contains enough address lines for the largest memory on the tristate bridge. Smaller off-chip memories might not use all of the most-significant address lines.

For example, a memory device with  $2^{10}$  locations uses 10 address bits, while a memory with  $2^{20}$  locations uses 20 address bits. If both these devices share the same tristate bridge, the smaller memory ignores the ten most significant Avalon-MM address lines.

### **Example Design with SRAM and Flash Memory**

This section demonstrates adding a 1-Mbyte SRAM and an 8-Mbyte flash memory to the example design. These memory devices connect to the system interconnect fabric through an Avalon-MM tristate bridge.

### Adding the Avalon-MM Tristate Bridge

In the **Avalon-MM Tristate Bridge** configuration wizard, check the **Registered inputs and outputs** option to maximize system  $f_{MAX}$ , which increases the read latency by two for both the SRAM and flash memory.

### Adding the Flash Memory Interface

The flash memory is  $8M \times 8$ -bit, which requires 23 address bits and 8 data bits. **Figure 8–12** shows the **Flash Memory (Common Flash Interface)** configuration wizard settings for the example design.

**Figure 8–12. Flash Memory Configuration Wizard**

### Adding the SRAM Interface

The SRAM device is  $256K \times 32$ -bit, which requires 18 address bits and 32 data bits. The example design uses a custom memory interface created with the SOPC Builder component editor. **Figures 8–13** through **8–18** shows the settings required on the various component editor tabs to implement an interface to this SRAM.

Figure 8–13. SRAM Interface Component Editor HDL Files Tab

Figure 8–14. SRAM Interface Component Editor Signals Tab

**Figure 8–15. SRAM Interface Component Editor Interfaces Tab**

Figure 8–16. SRAM Interface Component Editor Component Wizard Tab

### Adding the PLL

To reduce clock skew, all components in this example design connect to `sys_clk` generated by the **PLL** component. Select the **PLL** from the list of available components. To configure the **PLL**, select **Launch Altera's ALTPLL MegaWizard**. For this example design you configure `p11.c0` as a 50 MHz clock. Figure 8–17 illustrates the configuration of this component.

Figure 8–17. PLL Parameters

### SOPC Builder System Contents Tab

Figure 8–18 shows the SOPC Builder system after adding the **Tristate bridge and memory interface** components, and configuring them appropriately on the **System Contents** tab. Figure 8–18 represents the complete example design in SOPC Builder.

**Figure 8–18. SOPC Builder System with SRAM and Flash Memory**

After generating the system, the top-level system module file `sopc_memory_system.v` contains the list of I/O signals for SRAM and flash memory that must be connected to FPGA pins:

```
output          chipselect_n_to_the_ext_ram;
output          read_n_to_the_ext_ram;
output          select_n_to_the_ext_flash;
output [ 22: 0] tri_state_bridge_address;
output [  3: 0] tri_state_bridge_byteenable;
input  [ 31: 0] tri_state_bridge_data;
output          tri_state_bridge_readn;
output          write_n_to_the_ext_flash;
output          write_n_to_the_ext_ram;
```

The Avalon-MM tristate bridge signals that can be shared are named after the instance of the tristate bridge component, such as `tri_state_bridge_data[31:0]`.

### *Connecting and Assigning Pins in the Quartus II Project*

Figure 8–19 shows the result of generating the system module for the complete example design.

**Figure 8–19. System Module with SDRAM and External Flash Memory**

Figure 8–20 shows the pin assignments in the Quartus II assignment editor for some of the SRAM and flash memory pins. The correct pin assignments depend on the target board.

**Figure 8–20. Pin Assignments for SRAM and Flash Memory**

	To	Location	I/O Bank	I/O Standard	General Function	Special Function	Reset
243	SRAM_BE_N[0]	PIN_M18	3	LVTTTL	Column I/O		
244	SRAM_BE_N[1]	PIN_F17	3	LVTTTL	Column I/O		
245	SRAM_BE_N[2]	PIN_J18	3	LVTTTL	Column I/O	RUP3	
246	SRAM_BE_N[3]	PIN_L17	3	LVTTTL	Column I/O	CLK15n

October 2005, v5.1.0	Chapter 8 was previously chapter 6. No change to content.	—
May 2005, v5.0.0	Initial release.	—

## Introduction

This chapter describes the design flow to develop a custom SOPC Builder component. The chapter describes the parts of a custom component and provides tutorial steps that guide you through the process of creating a custom component, integrating it into a system, and testing it in hardware.

This chapter is divided into the following sections:

- [“Component Development Flow” on page 9–3.](#)
- [“Design Example: Checksum Master” on page 9–9.](#) This design example demonstrates developing a component with both Avalon® Memory-Mapped (Avalon-MM) master and slave ports.
- [“Sharing Components” on page 9–29.](#) This section shows you how to use components in other systems, or share them with other designers.

## SOPC Builder Components and the Component Editor

Typically, an SOPC Builder component is composed of the following four parts:

- HDL files that define the component’s functionality as hardware.
- `_hw.tcl` file that describes the SOPC Builder related characteristics, such as interface behaviors.
- C-language files that define the component register map and driver software that allows programs to control the component if the component is accessed by a processor using software.

The component editor guides you through the creation of a module or `hw.tcl` file to describe your component. By following the procedures described in this document, you learn to use the component editor and turn any custom logic module into an SOPC Builder component.

After your component has been created, you can instantiate it in an SOPC Builder system and make connections in the same manner as other SOPC Builder components. You can share your component with other designers to encourage design reuse.

## Prerequisites

This chapter assumes that you are familiar with the following:

- Building systems with SOPC Builder. For details, refer to the *Introduction to SOPC Builder* chapter in volume 4 of the *Quartus II Handbook*.
- SOPC Builder components. For details, refer to the *SOPC Builder Components* chapter in volume 4 of the *Quartus II Handbook*.
- Basic concepts of the Avalon-MM interface.

## Hardware and Software Requirements

To use the design example in this chapter, you must have the following:

- Design files for the example design—A hyperlink to the design files appears next to the chapter, *Developing Components for SOPC Builder*, on the SOPC Builder literature page.
- Quartus® II Software version 7.2 or higher—Both Quartus II Web Edition and the fully licensed version will work with the example design.
- Nios® II Embedded Design Suite (EDS) version 1.1 or higher—Both the evaluation edition and the fully licensed version will work with the example design.
- Nios development board and an Altera® USB-Blaster™ download cable (Optional)—You can use any of the following Nios development boards:
  - Stratix® III Edition
  - Stratix® II Edition
  - Stratix Edition
  - Stratix Professional Edition
  - Cyclone® III Edition
  - Cyclone II Edition
  - Cyclone™ Edition

If you do not have a development board, you can follow the hardware development steps, but you cannot download the complete system to a working board.

You can download the Quartus II Web Edition software and the Nios II EDS, Evaluation Edition for free from the Altera Download Center at [www.altera.com](http://www.altera.com).

# Component Development Flow

This section provides an overview of the development process for custom SOPC Builder components.

## Typical Design Steps

A typical development sequence for an SOPC Builder component includes the following items:

1. Specification and definition.
  - a. Define the functionality of the component.
  - b. Determine the number and type of component interfaces, whether or not Avalon MM, Avalon ST, interrupt, or the interfaces that are used.
  - c. Determine the component clocking requirements; what interfaces are synchronous to what clock inputs.
  - d. If you want a microprocessor to control the component, specify the application program interface (API) to access and control the hardware.
  - e. Specify the hardware functionality.
  - f. If you want a microprocessor to control the component, specify the register set and application program interface (API) to access and control the component.
2. For hardware development, create an HDL file that describes the hardware in either Verilog or VHDL, and test the component alone in simulation or hardware to verify correct operation.
3. SOPC Builder import.
  - a. Use the component editor to create an **hw.tcl** file that describes the component.
  - b. Instantiate the component into a simple SOPC Builder system.
  - c. Test register-level accesses to the component in hardware or simulation using a microprocessor, such as the Nios II processor.

When importing an HDL file into the component editor, any parameter definitions that are dependent upon other defined parameters cause an error. For example the following *DEPTH* parameter, though legal Verilog HDL syntax in the Quartus II software, causes an error in the component editor syntax checker:

```
parameter WIDTH = 32;  
parameter DEPTH = ((WIDTH == 32) ? 8 : 16);
```

To avoid this error, use *localparam* for the dependent parameter instead, as shown below:

```
parameter WIDTH = 32;  
localparam DEPTH = ((WIDTH == 32) ? 8 : 16);
```

4. Software Driver Development.
  - a. Create a C header file that defines the hardware-level register map for software if the component is accessed by software.
  - b. Write the driver software.
5. Finalize the component and distribute it for design reuse.

The following sections provide more details about the hardware and software design steps.

## Hardware Design

As with any logic design process, the development of SOPC Builder component hardware begins after the specification phase. Creating the HDL design is an iterative process, as you write and verify the HDL logic against the specification.

The architecture of a typical component consists of the following functional blocks:

- *Task Logic*—Implements the component's fundamental function. The task logic is design dependent.
- *Interfaces*—Provide a standard way of providing data to or getting data from the components and of controlling the functioning of the components.

For interface specifications, refer to the following at [www.altera.com](http://www.altera.com):

- *Avalon Memory-Mapped Interface Specification*—Accommodate peripheral development for the SOPC environment.
- *Avalon Streaming Interface Specification*—Accommodate the development of high bandwidth low latency components for the SOPC environment.

Figure 9–1 shows the top-level blocks of a checksum component, which includes both Avalon-MM master and slave ports.

Figure 9–1. Checksum Component with Avalon-MM Master and Slave Ports

## Software Design

If you want a microprocessor to control your component, then you must provide software files that define the software view of the component. At a minimum, you must define the register map for each Avalon MM slave port that is accessible to a processor.

Typically, the header file declares macros to read and write each register in the component, relative to a symbolic base address assigned to the component. The following example shows the register map of the checksum component for use by the Nios II processor.

---

**Example 9–1. Example: Register Map for the Checksum Component**

```
#ifndef __ALTERA_AVALON_CHECKSUM_REGS_H__
#define __ALTERA_AVALON_CHECKSUM_REGS_H__

#include <io.h>

/* Basic address, read and write macros. */

#define IOADDR_ALTERA_AVALON_CHECKSUM_ADDR(base)
__IO_CALC_ADDRESS_NATIVE(base, 0)
#define IORD_ALTERA_AVALON_CHECKSUM_ADDR(base)          IORD(base, 0)
#define IOWR_ALTERA_AVALON_CHECKSUM_ADDR(base, data)    IOWR(base, 0, data)

#define IOADDR_ALTERA_AVALON_CHECKSUM_LENGTH(base)
__IO_CALC_ADDRESS_NATIVE(base, 1)
#define IORD_ALTERA_AVALON_CHECKSUM_LENGTH(base)        IORD(base, 1)
#define IOWR_ALTERA_AVALON_CHECKSUM_LENGTH(base, data)  IOWR(base, 1, data)

#define IOADDR_ALTERA_AVALON_CHECKSUM_CTRL(base)
__IO_CALC_ADDRESS_NATIVE(base, 2)
#define IORD_ALTERA_AVALON_CHECKSUM_CTRL(base)          IORD(base, 2)
#define IOWR_ALTERA_AVALON_CHECKSUM_CTRL(base, data)    IOWR(base, 2, data)

#define IOADDR_ALTERA_AVALON_CHECKSUM_RESULT(base)
__IO_CALC_ADDRESS_NATIVE(base, 4)
#define IORD_ALTERA_AVALON_CHECKSUM_RESULT(base)        IORD(base, 4)

#define IOADDR_ALTERA_AVALON_CHECKSUM_STATUS(base)
__IO_CALC_ADDRESS_NATIVE(base, 5)
#define IORD_ALTERA_AVALON_CHECKSUM_STATUS(base)        IORD(base, 5)

/* Masks. */

#define ALTERA_AVALON_CHECKSUM_CTRL_GO_MSK              (0x1)
#define ALTERA_AVALON_CHECKSUM_STATUS_DONE_MSK         (0x2)
#define ALTERA_AVALON_CHECKSUM_LENGTH_MSK              (0xFFFF)
#define ALTERA_AVALON_CHECKSUM_RESULT_MSK              (0xFFFF)

/* Offsets. */

#define ALTERA_AVALON_CHECKSUM_CTRL_GO_OFST            (0)
#define ALTERA_AVALON_CHECKSUM_STATUS_BSY_OFST        (0)
#define ALTERA_AVALON_CHECKSUM_STATUS_DONE_OFST       (1)

#endif /* __ALTERA_AVALON_CHECKSUM_REGS_H__ */
```

---

Software drivers abstract hardware details of the component so that software can access the component at a high level. The driver functions provide the software an API to access the hardware. The software requirements vary according to the needs of the component. The most common types of routines initialize the hardware, read data, and write data.

When developing software drivers, it is instructive to look at the software files provided for other ready-made components. The Nios II EDS provides many components you can use as reference. See the *<Nios II EDS install path>/components/* directory for examples.

For details on writing drivers for the Nios II hardware abstraction layer (HAL), refer to the *Nios II Software Developer's Handbook*.

## Verifying the Component

You can verify the component in incremental stages, as you complete more of the design. Typically, you first verify the hardware logic as a unit (which might consist of multiple smaller stages of verification), and later you verify the component in a system.

### *Unit Verification*

To test the task logic block alone, you use your preferred verification method(s), such as HDL simulation tools.

After you package the HDL files into a component using the component editor, the Nios II EDS offers an easy-to-use method to simulate read and write transactions to the component. Using the Nios II processor's robust simulation environment, you can write C code for the Nios II processor that initiates read and write transfers to your component. You can verify the results either on the ModelSim simulator or on hardware, such as a Nios development board.

For more information, refer to *AN 351: Simulating Nios II Embedded Processor Designs*.

### *System-Level Verification*

After you package an **hw.tcl** file with the component editor, you can instantiate the component in a system, and verify the functionality of the overall system module.

SOPC Builder provides support for system-level verification for HDL simulators such as ModelSim. SOPC Builder automatically produces a test bench for system-level verification.

You can include a Nios II processor in your system to enhance simulation capabilities during the verification phase. Even if your component has no relationship to the Nios II processor, the auto-generated ModelSim simulation environment provides an easy-to-use starting point.

## Design Example: Checksum Master

This section uses a **checksum master** design example to demonstrate the steps to create a component and instantiate it in a system. This component includes both Avalon-MM master and slave ports.

In this section, you will perform the following steps:

1. Install the design files.
2. Review the example design specifications.
3. Create an SOPC Builder component.
4. Instantiate the component in an SOPC system.
5. Compile the hardware design in the Quartus II software, and download the design to a target board.
6. Exercise the hardware using the Nios II processor.

### Install the Design Files

Before you proceed, you must install the Nios II development tools and download the **checksum master** example design from the Altera website. The hardware design used in this chapter is based on the **standard** hardware example design included with the Nios II EDS.

Perform the following steps to set up the design environment:

1. On your host computer file system, locate the following directory:

```
<Nios II EDS install path>/examples/<verilog or vhdl>/<board  
version>/standard
```

Each development board has a VHDL and Verilog HDL version of the design. You can use either of these design examples. [Table 9–1](#) shows the names of the directories for each Nios development board.

<b>Nios Development Board</b>	<b>Design Directory</b>
Stratix III Edition	niosII_stratixIII_3sl150
Stratix II Edition	niosII_stratixII_2s60_ROHS, niosII_stratixII_2s60, niosII_stratixII_2s60ES
Stratix Edition	niosII_stratix_1s10, niosII_stratix_1s40
Stratix Professional Edition	niosII_stratix_1s40
Cyclone III Edition	niosII_cycloneIII_3c120, niosII_cycloneIII_3c25
Cyclone II Edition	niosII_cycloneII_2c35
Cyclone Edition	niosII_cyclone_1c20

- Copy the **standard** directory to a new location. By copying the design files, you avoid corrupting the original design and avoid issues with file permissions. This document refers to the newly-created directory as the *<Quartus II project>* directory.
- Copy the file **altera\_avalon\_checksum.zip** to the *<Quartus II project>* directory and unzip it. The design and test files listed in [Table 9–2](#) are added to *<Quartus II project>/altera\_avalon\_checksum* directory.

## Review the Example Design Specifications

This section discusses the design specifications for the provided checksum example design, giving details on each of the following topics:

- Checksum Design Files
- Functional Specification
- Master Task Logic
- Register File
- Avalon-MM Master Interface
- Avalon-MM Slave Interface
- Software API

## Checksum Design Files

Table 9–2 lists the contents provided in the `altera_avalon_checksum` directory.

<i>Table 9–2. Checksum Design Files Directory</i>	
File Name	Description
<code>/altera_avalon_checksum</code>	Contains all the HDL and software files for the component. All the HDL files must be in the same directory and be consistent in name with the <code>hw.tcl</code> file. (1)
<code>altera_avalon_checksum.v</code>	The top-level HDL file instantiates the task logic, Avalon-MM master and slave interfaces and the register files.
<code>checksum_task_logic.v</code>	This Verilog HDL file contains the core functionality of the checksum component.
<code>read_master.v</code>	This file contains the logic for the Avalon-MM read master interface.
<code>s1_slave.v</code>	This file contains logic for reading and writing to the checksum registers
<code>altera_avalon_checksum_sw.tcl</code>	This is the checksum software driver configuration file for the Nios II command line flow.
<code>/inc</code>	This sub-directory includes header files defining the low-level hardware interface.
<code>altera_avalon_checksum_regs.h</code>	This file defines macros to access registers in the checksum component.
<code>/test_software</code>	This sub-directory includes an example program to test the component hardware and software.
<code>test_checksum.c</code>	The test program initializes and array of data for the checksum component to read and compute the checksum.

Note to Table 9–2:

- (1) The component editor creates the `altera_avalon_checksum_hw.tcl` file and stores it in the `altera_avalon_checksum` directory.

## Master Task Logic

The **checksum master** reads a programmable number of 16-bit values to calculate a checksum. The `status` register sets its `DONE` bit when the checksum master completes. Software polls the `DONE` bit to determine when the calculation is complete.

### Register File

The register file provides access to the configuration, status, and results registers shown in Table 9–3. The design maps each register to a unique offset in the Avalon-MM slave port address space. The registers are read, write, or read only.

Register Name	Offset	Access	Description
Address	0x00	Read/Write	32-bit start address for checksum calculations.
Length	0x04 + 4	Read/Write	16-bit byte count for the checksum calculation.
Control	0x08 + 8	Read/Write	Bits [7:1] are reserved. Bit[0] is the GO bit.
Reserved	0x0C + 12	—	—
Result	0x10 + 16	Read	16-bit result of the checksum calculation.
Status	0x14 + 20	Read	Bits [7:2] are reserved. Bit[1:0] are DONE and BUSY.
Reserved	0x18	—	—
Reserved	0x1C	—	—

Table 9–4 shows the layout of the bits and fields of these registers.

Offset	31	16	15	1	0
0x00	address				
0x04	reserved		length		
0x08	reserved				GO
0x10	reserved		result		
0x14	reserved			DONE	BUSY

### Avalon-MM Clock Interface

The **checksum** component includes an Avalon-MM clock interface to bring in a system clock and reset into the checksum component as shown in Figure 9–1. The clock interface will be connected to each Avalon-MM master and slave interface in the **Interface** tab.

Table 9–5 lists the clock interface signals that comprise the Avalon-MM master port.

Signal Name in HDL	Avalon-MM Signal Type	Width	Dir	Notes
csi_clockreset_clk	clk	1	In	Synchronization clock for the component. All signals are synchronous to clk.
csi_clockreset_reset_n	reset_n	1	In	Resets the entire Avalon-MM system.

### *Avalon-MM Master Interface*

The **checksum master** component includes an Avalon-MM master port that reads from memory. The component's Avalon-MM master port has the following characteristics:

- It is synchronous to the Avalon-MM master clock interface.
- It initiates master transfers to the system interconnect fabric.

Table 9–6 lists the signals that comprise the Avalon-MM clock port.

Signal Name in HDL	Avalon-MM Signal Type	Width	Dir	Notes
avm_m1_address	address	32	Out	Byte address aligned on word boundary.
avm_m1_byteenable	byteenable	4	Out	Enables specific byte lanes on ports greater than 8 bits.
avm_m1_read_n	read_n	1	Out	Read request signal.
avm_m1_readdata	readdata	32	In	Uni-directional data.
avm_m1_waitrequest	waitrequest	1	In	Forces master port to wait until the system interconnect fabric is ready to proceed with the transfer.

### *Avalon-MM Slave Interface*

The Avalon-MM slave port handles simple read and write transfers to the registers. The slave port has the following characteristics:

- Synchronous to the Avalon-MM clock interface.

- Readable and writable.
- Zero wait states for writing and one wait state for reading.
- No setup or hold restrictions for reading and writing.
- Uses native address alignment, because the slave port is connected to registers rather than a memory device.

**Table 9–7. Table of Checksum Avalon-MM Slave Port Signal Names and Avalon Signal Types**

Signal Name in HDL	Avalon-MM Signal Type	Width	Dir	Notes
avs_s1_address	address	3	In	A byte address.
avs_s1_read_n	read_n	1	In	Read request input.
avs_s1_write_n	write_n	1	In	Write request input.
avs_s1_chipselect_n	chipselect	1	In	Chip-select to slave port. Slave port ignores all other signals unless it is selected.
avs_s1_readdata	readdata	32	Out	Uni-directional read data
avs_s1_writedata	writedata	32	In	Uni-directional write data

### Software API

The `altera_avalon_checksum_regs.h` file has been provided to include macros to read and write the checksum slave registers.

## Create an SOPC Builder component

In this section you specify the hardware interfaces to the component, and define the behavior of each interface signal.

### Open the Quartus II Project and Start the Component Editor

To open SOPC Builder from the Quartus II software, perform the following steps:

1. Start the Quartus II software.
2. Open the project `standard.qpf` in the `<Quartus II project>` directory.
3. On the Tools menu, click **SOPC Builder**. SOPC Builder appears, displaying a ready-made example design containing a Nios II processor and several components.
4. On the File menu, click **New Component**. The component editor appears, displaying the **Introduction** tab.

### *HDL Files Tab*

In this section you associate the component's top-level HDL file with the component's hardware Tcl file using the **HDL files** tab. Perform the following steps:

1. Click the **HDL Files** tab.
2. Click **Add HDL File**.
3. Browse to the `<Quartus II project>/altera_avalon_checksum` directory and select the top level HDL file **altera\_avalon\_checksum.v** and click **Open**.

The first file you add to the component editor must be the top-level HDL file of your design.

4. Click **OK** when a message indicated analysis is complete.
5. You can now add lower-level design files. Click **Add HDL File** and add the **checksum\_task\_logic.v**, **read\_master.v**, and **sl\_slave.v** files to the component list.
6. Select the top level module of your component by clicking in the **Top Level Module** list and selecting **altera\_avalon\_checksum**.
7. If you plan to simulate your component, click **Add Simulation File** to add all of the files required for simulation.

The component editor now displays error messages. You are instructed to fix them in later steps.

### *Signals Tab*

For every I/O signal present on the top-level HDL module, you must map the signal name to a valid signal type using the **Signals** tab. If the signal name includes a recognized signal type (such as `write` or `address`), the component editor guesses the signal's type. If the component editor cannot determine the signal type, it assigns the type `export`.

This design uses the automatic type and interface recognition feature of the component editor to quickly allow the component editor to assign the component signals to the appropriate interface and signal type. To change the type assigned, click at the right edge of the **Signal Type** column for the signal in question. A pull-down menu provides other choices.

For more information on the automatic type and interface recognition feature see the *Component Editor* chapter in volume 4 of the *Quartus II Handbook*.

This design includes three interfaces: clock (clockreset), slave (s1), and master (m1) as illustrated in [Figure 9-2](#). The signal types and polarities are derived from the signal names.

Figure 9–2. The Signals Tab

The screenshot shows the 'Component Editor' window with the 'Signals' tab selected. The window title is 'Component Editor' and it has a menu bar with 'File' and 'Templates'. Below the menu bar are tabs for 'Introduction', 'HDL Files', 'Signals', 'Interfaces', and 'Component Wizard'. The 'Signals' tab is active, showing a section titled 'About Signals' with a table of signals.

Name	Interface	Signal Type	Width	Direction
csi_clockreset_clk	clockreset	clk	1	input
csi_clockreset_rese...	clockreset	reset_n	1	input
avs_s1_address	s1	address	3	input
avs_s1_chipselect_n	s1	chipselect_n	1	input
avs_s1_read_n	s1	read_n	1	input
avs_s1_write_n	s1	write_n	1	input
avs_s1_writedata	s1	writedata	32	input
avs_s1_readdata	s1	readdata	32	output
avm_m1_address	m1	address	32	output
avm_m1_byteenable	m1	byteenable	4	output
avm_m1_read_n	m1	read_n	1	output
avm_m1_readdata	m1	readdata	32	input
avm_m1_waitrequest	m1	waitrequest	1	input

Below the table are two buttons: 'Add Signal' and 'Remove Signal'. At the bottom of the window, there is an information panel with an 'Info' icon and the text 'Info: No errors or warnings.' Below this panel are four buttons: 'Help', 'Prev', 'Next', and 'Finish...'.

### Interfaces Tab

After assigning signals to interfaces, the **Interfaces** tab allows you to further configure the properties of all interfaces on the component.

Perform the following steps to configure the Avalon slave port:

1. Click the **Interfaces** tab. The component editor displays the Avalon-MM slave port (s1) from the previous tab.
2. Remove any unused interfaces by clicking **Remove Interfaces with No Signals**.

This removes the default provided clock and export\_0 interfaces in the component editor, as you created your own interfaces with the automatic type and interface recognition feature.

The component editor now displays the clockreset clock input interface, s1 slave interface, and the m1 master interface.

3. For the Avalon-MM slave port (s1) set the clock and reset for the slave interface by clicking on **Associated Clock** and then select **clockreset**.
4. Change the default settings for the slave port to match those given in [Table 9–8](#).

**Table 9–8. Settings for Avalon-MM Slave Port (Part 1 of 2)**

Slave Settings	Value	Description
Slave Addressing	Native	Indicates that the slave ports uses address-mapped registers.
Minimum Arbitration Shares	1	Arbitration shares modify the default round-robin arbitration scheme which provides equal access to all devices.
Can receive stderr/stdout	No	—
Interleave Bursts	No	—
Read Latency	0	—
Max. Pending Read Transactions	0	—
Slave Timing	Value	Description
Setup	0	Indicates that the slave port responds to a read or write request in a single clock cycle.
Read Wait	1	Indicates that the slave port responds to read requests one cycle after they are made (one read waitstate).

**Table 9–8. Settings for Avalon-MM Slave Port (Part 2 of 2)**

<b>Slave Settings</b>	<b>Value</b>	<b>Description</b>
Write Wait	0	Indicates that the slave port responds to write requests in a single clock cycle and does not need write waitstates.
Hold	0	Indicates that there is not a hold time requirement.

5. For the Avalon-MM master port (m1) set the clock and reset for the master interface by clicking on **Associated Clock** and then select **clockreset**.
6. Leave all other Avalon-MM master settings as the default settings, as shown in [Figure 9–4](#).

Figure 9-3 illustrates the slave settings.

Figure 9-3. Avalon-MM Slave Interfaces Settings

The Avalon-MM master port uses the default settings. [Figure 9-4](#) illustrates these settings.

Figure 9-4. Avalon-MM Masters Interfaces Settings

### Component Wizard Tab

The **Component Wizard** tab allows you to control how SOPC Builder presents the components to a user. Perform the following steps to configure the user presentation of the component. The component editor creates a default name for the component, based on the name of the top-level design module.

1. Click the **Component Wizard** tab.
2. For this example, do not change the default settings for **Component Name** or **Component Version**.
3. For the **Component Group** type the following: `User Logic`
4. Complete the remaining fields, such as **Description** and **Created By**.
5. Click **Preview the Wizard** to preview the component wizard as it will appear in SOPC Builder. [Figure 9-5](#) illustrates the component wizard preview.
6. Close the Preview window.

**Figure 9-5. Component Wizard**

### Save the Component

Perform the following steps to save the component and exit the component editor:

1. Click **Finish**. A message describes the file that is created for the component.
2. Click **Yes** to save the file. The component editor saves the **altera\_avalon\_checksum\_hw.tcl** file in the same directory that you stored the top-level component HDL file. The component editor closes, and you return to SOPC Builder.

3. Locate the new **checksum** component in the list of available components under the **User Logic** group. The component is added to the SOPC Builder search path. Right-clicking on a component in the list allows you to edit the component.

### Instantiate the Component in Hardware

At this point, the new component is ready to instantiate in an SOPC Builder system. The remaining steps for this design example illustrate one possible method of instantiation that includes the following general steps:

1. Add the **checksum master** to the SOPC Builder system.
2. Compile the hardware design and download to the target board.

#### *Add the checksum Master Component to the SOPC Builder System*

Perform the following steps to add a **checksum master** component to the SOPC Builder system:

1. On the SOPC Builder **System Contents** tab, select the new component **altera\_avalon\_checksum** under the **User Logic** group in the list of available components, and click **Add**. The configuration wizard for the **checksum master** component appears.
2. Click **OK**. The component **altera\_avalon\_checksum\_inst** appears in the table of active components.
3. Connect the **altera\_avalon\_checksum\_inst** m1 master port to a memory in your system.

The test program uses an on-chip memory peripheral called **onchip\_ram**. If your SOPC Builder system does not have an on-chip memory you should add an on-chip memory to the design. The test program requires that the name of the on-chip RAM and the component name used in the test program match. Connect the on-chip RAM to the Nios II data master.

4. To start generating the system, click **Generate**
5. After system generation completes successfully, exit SOPC Builder.

### *Compile the Hardware Design and Download to the Target Board*

At this point, you have created an SOPC Builder system that uses the **checksum** component. The **checksum** component adds no additional I/O signals to the SOPC Builder system top-level so you only need to compile the design in the Quartus II software.

Perform the following steps to compile the hardware design and download it to the target board.

1. On the Processing menu, click **Start Compilation** to start compiling the hardware design. The compilation begins.

If you performed all prior steps correctly, the Quartus II compilation finishes successfully after several minutes, and generates a new SRAM Object File (**.sof**) for the project.

You can only perform the remaining steps in this chapter if you have a development board.

2. Connect your host computer to the development board using an Altera download cable, such as the USB Blaster, and apply power to the board.
3. On the Tools menu, click **Programmer** to open the Quartus II Programmer.
4. Use the Programmer window to download the following FPGA configuration file to the board: *<Quartus II project>/standard.sof*.

At this point, you have completed all the steps to create a hardware design and download it to hardware.

### **Exercise the Hardware Using Nios II Software**

The **checksum master** example design is based on the Nios II processor. The example design files provide a C test program that programs the component to calculate a checksum and then polls the component to determine if it completes the calculation successfully. In this section you perform the following steps:

1. Start the Nios II IDE and create a new Nios II IDE project.
2. Build and run the C test program.
3. View the results.

To complete this section, you must have performed all prior steps, and successfully configured the target board with the hardware design.

### *Start the Nios II IDE and Create a New IDE Project*

Perform the following steps to start the Nios II IDE and create a new IDE project:

1. Start the Nios II IDE.
2. On the Window menu, point to **Open Perspective** and click **Other**, then click **Nios II C/C++** to open the Nios II C/C++ perspective.
3. On the File menu, point to **New** and then click **C/C++ Application** to start a new project. The first page of the **New Project** wizard appears.
4. Under **Select Project Template**, select **Blank Project**.
5. In the **Name** box, type `test_checksum`.
6. Ensure that **Specify Location** is turned off so that you use the default software directory under your standard board as shown in [Figure 9-6](#).

Figure 9–6. Create a New Project

7. Click **Browse** under **Select Target Hardware**. The **Select Target Hardware** dialog box appears.
8. Browse to the *<Quartus II project>* directory.
9. Select the file **std\_<FPGA>.ptf**.
10. Click **Open** to return to the New Project wizard. The **SOPC Builder System** and the **CPU** fields are now specified.
11. Click **Finish**. After the IDE successfully creates the new project, the C/C++ Projects view contains two new projects, **test\_checksum** and **test\_checksum\_syslib**.

### *Compile the Software Project and Run on the Target Board*

In this section you compile the C test program provided with the checksum design files, and then download it to the target board.

First, perform the following steps to associate the source files with the new C/C++ project:

1. Copy **test\_checksum.c** from `<Quartus II project>/altera_avalon_checksum/test_software` to the `<Quartus II project>/software/test_checksum` directory.
2. In the Nios II IDE C/C++ Projects view, right-click **test\_checksum** and click **Refresh**, directing the IDE to recognize the new file in the project directory.

The project is now ready to compile and run. Perform the following steps:

1. Right-click the project **test\_checksum** in the Nios II C/C++ Projects view and click **Build Project** to compile the program. The first time you build the project, it can take a few minutes for the compilation to finish.
2. After compilation completes, select **test\_checksum** in the C/C++ Projects view.
3. On the Run menu, click **Run**. The **Run** dialog box appears.
4. Select **Nios II Hardware**, and click **New**. A new run/debug configuration named **test\_checksum Nios II HW configuration** appears.
5. If the **Run** button (in the bottom right of the **Run** dialog box) is disabled, perform the following steps:
  - a. Click the **Target Connection** tab.
  - b. Click **Refresh** next to the **JTAG cable** list.
  - c. In the **JTAG cable** list, select the download cable you want to use.
  - d. Click **Refresh** next to the **JTAG device** list.
6. Click **Run**.

- View the results: The **Console** view in the IDE displays messages similar to the following: 0x5a5a.

You have finished all steps for the **checksum** design example.

## Sharing Components

When you create a component, component editor by default saves the (**\_hw.tcl**) in the same directory as the top-level HDL file. Where appropriate, files referenced by the **\_hw.tcl** file all use relative paths so that files can easily be moved and copied together. To promote design reuse, you can use the component in different projects, and you can share your component with other designers.

Perform the following steps to share a component:

- In your computer's file system, move the component directory to a central location, outside any particular Quartus II project's directory. For example, you could create a directory **c:\my\_component\_library** to store your custom components.

If you create a new component library under the Quartus II project directory and then add individual components to that new component library, for example:  
`<Quartus_rootdir>\sopc_builder\my_project\my_project_lib\component1\`, SOPC Builder cannot find the components. You must add the directory for **component1** to your library path.

SOPC Builder will find your components if you place your components in the **projectdir\ip** directory. Altera recommends that you do so.

- On the Quartus II Assignments menu, click **Settings**. The **Settings** dialog box appears.
- In the **Categories** list, click **Libraries**.
- Under **Global libraries**, add the path to the enclosing directory of the component directory. For example, for a component directory **c:\my\_component\_library\checksum\_master\**, add the path **c:\my\_component\_library**.

If you need to share a component library directory across projects, you can add items to the **SOPC Builder Tools\Options\IP Search Path** settings. However, in the 7.2 version of the Quartus II software, this specifies component directories, and not library directories.

To use the newly created component in another SOPC Builder system, you must perform one of the following:

- Copy the component and its related files into the IP subdirectory of the project where it is to be used. For example, to use the component in the **project 2** project, simply copy the Tcl File (.tcl) and the reference files to **project2/ip/checksum**, and they will be found automatically.
- Alternatively, you can place the Tcl File (.tcl) and related files elsewhere in a component library, such as **L:/components/checksum/**, and add the library location to see the search path via **SOPC Builder/Tools/Options/IP Search Path**.

## Document Revision History

Table 9–9 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007, v7.2.1	Updated instructions on how to develop components to match updated GUI.	—
October 2007, v7.2.0	Updated instructions on how to develop components to match new GUI.	—
May 2007, v7.1.0	Changed example component from a pulse width modulator with that only has an Avalon-MM slave interface to a checksum master that includes both Avalon-MM master and slave interfaces.	Changed the example design to one with more practical applications. Updated instructions for the 7.1 release.
March 2007, v7.0.0	No change from previous release.	—
November 2006, v6.1.0	Chapter 9 was previously chapter 10. No change to content.	—
May 2006, v6.0.0	Chapter 10 was previously chapter 9. No change to content.	—
October 2005, v5.1.0	Chapter 9 was previously chapter 7. No change to content.	—
August 2005, v5.0.1	Corrected Table 7-5.	—
May 2005, v5.0.0	No change from previous release.	—
February 2005, v1.0	Initial release.	—

---

This section provides information on Avalon Memory-Mapped (Avalon-MM) and Avalon Streaming (Avalon-ST) components that can be added to SOPC Builder systems. The components described in these chapters help you to create and optimize your SOPC Builder system. They are provided for free and can be used without a license in any design targeting an Altera device.

This section includes the following chapters:

- [Chapter 10, Avalon Memory-Mapped Bridges](#)
- [Chapter 11, Avalon Streaming Interconnect Components](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Introduction to Bridges

This chapter introduces the concept of Avalon® Memory-Mapped (Avalon-MM) bridges, and describes the Avalon-MM bridge components provided by Altera® for use in SOPC Builder systems.

A bridge, in the context of SOPC Builder, is a component that acts as part of the system interconnect fabric. Bridges are not end-points for data, but rather affect the way data is transported between other components. By manually inserting Avalon-MM bridges between Avalon-MM master and slave ports in a system, you can control system topology, which in turn affects the interconnect that SOPC Builder generates. Manual control of the interconnect can result in higher performance and/or lower logic utilization.

Altera provides the Avalon-MM bridge, which is described in this chapter:

- [“Avalon-MM Pipeline Bridge” on page 10–9](#)

### Structure of a Bridge

A bridge has one Avalon-MM slave port and one Avalon-MM master port, as shown in [Figure 10–1](#). In an SOPC Builder system, one or more master ports connect to the bridge’s slave port to control the bridge. The bridge’s master port connects, in turn, to one or more slave ports. You configure the master-slave pairs manually with the SOPC Builder GUI. In [Figure 10–1](#), all three masters have a logical connection to all three slaves, although physically each master only connects to the bridge.

**Figure 10–1. Example of an Avalon-MM Bridge in an SOPC Builder System**

A bridge issues transfers on its master port in the same order in which they were received. Transfers initiated to the bridge's slave port propagate to the master port in the same order in which they were initiated on the slave port.

If you use either the Avalon-MM pipeline bridge or the Avalon-MM clock-crossing bridge in your system discussed in the SOPC Builder chapter, automatic pipelining feature is disabled.

For details on the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification*.

## Reasons for Using a Bridge

Reasons you might use an Avalon-MM bridge include:

- Increase the  $f_{MAX}$  of your system
- Control system topology
- Specify separate clock domains for master-slave pairs

If there are no bridges between master-slave pairs, SOPC Builder generates system interconnect fabric with maximum parallelism so that all masters can drive transactions to and from all slaves concurrently as long as each master is trying to access a different slave. This default behavior incurs the cost of additional arbiters and multiplexers decreasing the  $f_{MAX}$  of the system. For high performance systems that do not require a large degree of concurrency, the default behavior might not provide optimal performance. With knowledge of the system and application, you can optimize the system interconnect fabric by inserting bridges to control the system topology.

Figure 10–2 and Figure 10–3 show an SOPC system without bridges. This system includes three CPUs, a DDR SDRAM controller, a message buffer RAM, a message buffer mutex, and a tristate bridge to an external SRAM.

**Figure 10–2. Example System Without Bridges — SOPC Builder View**

Figure 10–3 illustrates the default system interconnect fabric that SOPC Builder would create for the system in Figure 10–2.

Figure 10–3. Example System without Bridges - System Interconnect View

Figure 10–4 and Figure 10–5 show how you can improve the logic utilization of the system interconnect fabric by inserting bridges. If the DDR SDRAM controller can run at 166 MHz and the CPUs accessing it can run at 120 MHz, inserting an Avalon-MM clock-crossing bridge between the CPUs and the DDR SDRAM has the following benefits:

- Allows the CPU and DDR interfaces to run at different frequencies.
- Places system interconnect fabric for the arbitration logic and multiplexer for the DDR SDRAM controller in the slower clock domain.

- Reduces the complexity of the interconnect logic in the faster domain, allowing the system to achieve a higher  $f_{MAX}$ .

In the system illustrated in Figure 10–4 the message buffer RAM and message buffer mutex must respond quickly to the CPUs, but each response includes only a small amount of data. Placing an Avalon-MM pipeline bridge between the CPUs and the message buffers results in the following benefits:

- Eliminates separate arbiter logic for the message buffer RAM and message buffer mutex, which reduces logic utilization and propagation delay, thus increasing the  $f_{MAX}$ .
- Reduces the overall size and complexity of the system interconnect fabric.

Figure 10–4. Example SOPC System with Bridges - SOPC Builder View

Figure 10–5 shows the system interconnect fabric that SOPC Builder would create for the system in Figure 10–4. Figure 10–5 is the same system that is pictured in Figure 10–3 except that it includes bridges to control system topology.

Figure 10–5. Example System with a Bridge

## Address Mapping for Systems with Avalon-MM Bridges

An Avalon-MM bridge has an address span and range which are defined as follows:

- The address *span* of an Avalon-MM bridge is the smallest power-of-two size that encompasses all of its slave's ranges.
- The address *range* of an Avalon-MM bridge is a numerical range from its base address to its base address plus its (span -1)

$$(1) \quad \text{range} = [\text{base\_address} .. (\text{base\_address} + (\text{span} - 1));$$

SOPC Builder follows several rules in constructing an address map for a system with Avalon-MM bridges:

1. The address span of each Avalon-MM slave is rounded up to the nearest power of two.
2. Each Avalon-MM slave connected to a bridge is assigned an address relative to the base address of the bridge. This address must be a multiple of its span. (See [Figure 10-6](#).)

**Figure 10-6. Avalon-MM Master and Slave Addresses**

3. In the example shown in [Figure 10-6](#), if the address span of Slave 1 is 0x100 and the address span of Slave 2 is 0x200, [Figure 10-7](#) illustrates the address span of the Avalon-MM bridge.

**Figure 10–7. The Address Span of an Avalon-MM Bridge**

### *Tools for Visualizing the Address Map*

The Base Address column of SOPC Builder displays the base address *offset* of the Avalon-MM slave relative to the base address of the Avalon-MM bridge to which it is connected. You can see the absolute address map for each master in the system by clicking the **Address Map** button on the **System Components** tab.

### *Differences between Avalon-MM Bridges and Avalon-MM Tristate Bridges*

You use Avalon-MM bridges to control topology and separate clock domains for on-chip components. You use tristate bridges to connect to off-chip components and to share pins, decreasing the overall pin count of the device. Tristate bridges are also used to change bi-directional input data into uni-directional input and output data signals. Tristate bridges are *transparent*, meaning that they do not affect the addresses of the components they connect to. All tristate bridges in a system have an address of 0x00000000 as [Figure 10–8](#) illustrates.

For more information about the Avalon-MM tristate bridge, refer to the *Building Memory Subsystems Using SOPC Builder* chapter in volume 4 of the *Quartus II Handbook*.

## Avalon-MM Pipeline Bridge

This section describes the hardware structure and functionality of the Avalon-MM pipeline bridge component.

### Component Overview

The Avalon-MM pipeline bridge inserts registers in the path between its master and slave ports. In a given SOPC Builder system, if the critical register-to-register propagation delay occurs in the system interconnect fabric, the pipeline bridge can help reduce this delay and improve system  $f_{MAX}$ .

The bridge allows you to independently pipeline different groups of signals that can create a critical timing path in the interconnect:

- Master-to-slave signals, such as address, write data, and control signals
- Slave-to-master signals, such as read data
- The `waitrequest` signal to the master

The Avalon-MM pipeline bridge can also be used to control topology without adding a pipeline stage. In this case, the pipeline bridge controls the wiring of the system interconnect fabric without adding any latency. To instantiate a bridge that does not add any pipeline stages, simply do not select any of the **Pipeline Options** on the parameter page. For the system illustrated in [Figure 10-5](#), a pipeline bridge that does not add a pipeline register stage is optimal because the CPUs require minimal delay from the message buffer mutex and message buffer RAM. There is one instance where a pipeline bridge that does not add any register stages will fail: If a slave does not have read latency, it cannot be connected to a bridge with no pipeline stages.

The Avalon-MM pipeline bridge component is SOPC Builder-ready and integrates easily into any SOPC Builder system.

## Functional Description

[Figure 10-9](#) shows a block diagram of the Avalon-MM pipeline bridge component.

Figure 10–9. Avalon-MM Pipeline Bridge Block Diagram

The following sections describe the component's hardware functionality.

### Interfaces

The bridge interface is composed of an Avalon-MM slave port and an Avalon-MM master port. The data width of the ports is configurable, which can affect how SOPC Builder generates dynamic bus sizing logic in the system interconnect fabric. Both ports support Avalon-MM pipelined transfers with variable latency. Both ports optionally support bursts of user-configurable length.

### Pipeline Stages and Effects on Latency

The bridge provides three optional register stages to pipeline the following groups of signals.

- Master-to-slave signals, including:
  - address
  - writedata
  - write
  - read
  - byteenable
  - chipselect
  - burstcount (optional)

- Slave-to-master signals, including:
  - readdata
  - readdatavalid
  - endofpacket
- The `waitrequest` signal to the master port

Including a register stage affects the timing and latency of transfers through the bridge, as follows:

- Including the register stages increases latency by one cycle in each direction, but also increases the  $f_{MAX}$  by reducing propagation delay.
- Write transfers from the Avalon-MM master to the slave interface of the bridge are decoupled from write transfers from the master interface of the bridge to the slave peripheral because Avalon-MM write transfers do not require an acknowledge from the slave.
- Including the `waitrequest` register stage increases the latency of master-to-slave signals by one cycle for each cycle in which the `waitrequest` signal is asserted.

### *Burst Support*

The bridge can optionally support bursts with configurable maximum burst length. When configured to support bursts, the bridge propagates bursts between master-slave pairs, up to the maximum burst length. Not having burst support is equivalent to a maximum burst length of one. In this case, the system interconnect fabric automatically decomposes master-to-bridge bursts into a sequence of individual transfers.

### *Example System with Avalon-MM Pipeline Bridges*

Figure 10–10 illustrates a system in which 7 Avalon-MM masters are accessing a single DDR2 memory controller. By inserting two Avalon-MM pipeline bridges, you can limit the complexity of the multiplexer that would be required without the intermediate pipeline stage.

**Figure 10–10. Seven Avalon-MM Masters Accessing One Avalon-MM Slave**

### Instantiating the Avalon-MM Pipeline Bridge in SOPC Builder

You use the Avalon-MM Pipeline Bridge MegaWizard interface in SOPC Builder to specify the hardware features. Refer to the *Building Memory Subsystems Using SOPC Builder* chapter in volume 4 of the *Quartus II Handbook* for a description of the options available on the **Parameter Settings** page of the configuration wizard.

## Device Support

Altera device support for the bridge components is listed in [Table 10–1](#). For each device family, a component provides either full or preliminary support:

- *Full support* means the component meets all functional and timing requirements for the device family and may be used in production designs.
- *Preliminary support* means the component meets all functional requirements, but might still be undergoing timing analysis for the device family; it can be used in production designs with caution.

**Table 10–1. Device Family Support**

Device Family	Avalon-MM Pipeline Bridge Support	Avalon-MM Clock-Crossing Bridge Support
Arria™ GX	Full	Preliminary
Stratix® III	Full	Preliminary
Stratix II GX	Full	Full
Stratix II	Full	Full
Stratix®	Full	Full
Cyclone™ III	Full	Preliminary
Cyclone II	Full	Full
Cyclone	Full	Full
HardCopy® II	Full	Full
MAX®	No support	No support
MAX II	Full	No support

## Installation and Licensing

The bridge components are included in the Altera MegaCore® IP Library, which is an optional part of the Quartus® II software installation. After you install the MegaCore IP Library, SOPC Builder recognizes the bridge components and can instantiate them into a system.

You can use the bridge components for free without a license in any design targeting an Altera device.

## Hardware Simulation Considerations

The bridge components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

## Software Programming Model

The bridge components do not have any user-visible control or status registers. Therefore, software cannot control or configure any aspect of the bridges during run-time. The bridges cannot generate interrupts.

## Referenced Documents

This chapter references the following documents:

## Document Revision History

[Table 10–2](#) shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Moved discussion of clock-crossing bridge from this chapter to chapter 2.	—
May 2007, v7.1.0	Initial release of the document.	The Avalon-MM Pipeline Bridge and Avalon-MM Clock-Crossing Bridge are new components provided in the Quartus II software v7.1 release.

## Introduction to Interconnect Components

Avalon® Streaming (Avalon-ST) interconnect components facilitate the design of high-speed, low-latency datapaths for the system-on-a-programmable-chip (SOPC) environment. Interconnect components, in the context of SOPC Builder, are components that act as a part of the system interconnect fabric. They are not end points, but adapters that allow you to connect different, but compatible, streaming interfaces. The Avalon-ST interconnect components are typically used to connect cores that send and receive high-bandwidth data, including multiplexed streams, packets, cells, time division multiplexed (TDM) frames, and digital signal processor (DSP) data.

The interconnect components that you add to an SOPC Builder system insert logic between a source and sink interface, enabling that interface to operate correctly. This chapter describes three Avalon-ST interconnect components, also called adapters:

- [“Timing Adapter” on page 11-3](#)—adapts between source and sink interfaces that do support the `ready` signal and those that do not.
- [“Data Format Adapter” on page 11-6](#)—adapts source and sink interfaces that have different data widths.
- [“Channel Adapter” on page 11-10](#)—adapts source and sink interfaces that have different settings for the `channel` signal.

All of these interconnect components adapt initially incompatible Avalon-ST source and sink interfaces so that they function correctly, facilitating the development of high-speed, low-latency datapaths.

### Interconnect Component Usage

Interconnect components can adapt the data or control signals of the Avalon-ST interface. Typical adaptations to control signals include:

- Adding pipeline stages to adjust the timing of the `ready` signal
- Tying signals that are not used by either the source or sink to 0 or 1

Typical adaptations to data signals include:

- Changing the number of symbols (words) that are driven per cycle
- Changing the number of channels driven

When the interconnect component adapts the data interface, it has one Avalon-ST sink interface and one Avalon-ST source interface, as shown in Figure 11–1. You configure the adapter components manually, using SOPC Builder. In contrast to the Avalon-MM interface, which allows you to create various topologies with a number of different master and slave components, the Avalon-ST interconnect components are always used to adapt point-to-point connections between streaming cores.

**Figure 11–1. Example of an Avalon-ST Interconnect Component in an SOPC Builder System**

For details about the system interconnect fabric, refer to the *System Interconnect Fabric for Streaming Interfaces* chapter in volume 4 of the *Quartus II Handbook*. For details about the Avalon-ST interface protocol, refer to *The Avalon Streaming Interface Specification*. Both are available at [www.altera.com](http://www.altera.com).

Figure 11–2 illustrates a datapath that connects a triple-speed Ethernet core to a scatter-gather DMA controller core using a timing adapter, data format adapter, and channel adapter so that the cores can interoperate.

**Figure 11–2. Avalon-ST Datapath Constructed Using Avalon Streaming Interconnect Components**

## Address Mapping

The signals of the Avalon-ST source and sink interfaces are mapped into the global Avalon address space.

## Timing Adapter

The timing adapter has two functions:

- It adapts source and sink interfaces that support the `ready` signal and those that do not.
- It adapts source and sink interfaces that have different ready latencies.

The timing adapter treats all signals other than the `ready` and `valid` signals as *payload*, and simply drives them from the source to the sink. [Table 11-1](#) outlines the adaptations that the timing adapter provides.

<b>Condition</b>	<b>Adaptation</b>
The source has <code>ready</code> , but the sink does not.	In this case, the source can respond to backpressure, but the sink never needs to apply it. The <code>ready</code> input to the source interface is connected directly to 1.
The source does not have <code>ready</code> , but the sink does.	The sink may apply backpressure, but the source is unable to respond to it. There is no logic that the adapter can insert that prevents data loss when the source asserts <code>valid</code> but the sink is not ready. The adapter provides simulation time error messages and an error indication if data is ever lost. The user is presented with a warning, and the connection is allowed.
The source and sink both support backpressure, but the sink's <code>ready</code> latency is greater than the source's.	The source responds to <code>ready</code> assertion or deassertion faster than the sink requires it. A number of pipeline stages equal to the difference in <code>ready</code> latency are inserted in the <code>ready</code> path from the sink back to the source, causing the source and the sink to see the same cycles as <code>ready</code> cycles.
The source and sink both support backpressure, but the sink's <code>ready</code> latency is less than the source's.	The source cannot respond to <code>ready</code> assertion or deassertion in time to satisfy the sink. A buffer whose depth is equal to the difference in <code>ready</code> latency is inserted to compensate for the source's inability to respond in time.

## Resource Usage and Performance

Resource utilization for the timing adapter depends upon the function that it performs. [Table 11-2](#) provides estimated resource utilization for seven different configurations of the timing adapter.

**Table 11–2. Timing Adapter Estimated Resource Usage and Performance**

Input Ready Latency	Output Ready Latency	Stratix® II and Stratix II GX (Approximate LEs)			Cyclone® II		Stratix (Approximate LEs)		
		f <sub>MAX</sub> (MHz)	ALM Count	Mem Bits	f <sub>MAX</sub> (MHz)	Logic Cells	f <sub>MAX</sub> (MHz)	Logic Cells	Mem Bits
1	2	500	2	0	420	2	422	1	0
1	3	500	2	0	420	3	422	2	0
1	4	500	4	0	420	4	422	3	0
1	0	500	21	80	420	183	422	20	80
2	1	456	21	80	401	188	317	21	80
3	1	456	21	80	401	188	317	21	80
4	1	456	21	80	401	188	317	21	80

## Instantiating the Timing Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. This section describes the options available on the **Parameter Settings** page of the configuration wizard.

### Input Interface Parameters

**Support Backpressure with the Ready Signal**—check this option to add the backpressure functionality to the interface. When the `ready` signal is used, the value for `READY_LATENCY` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.

### Output Interface Parameters

**Support Backpressure with the Ready Signal**—check this option to add the backpressure functionality to the interface. When the `ready` signal is used, the value for `READY_LATENCY` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.

### Common to Input and Output Interfaces

The following parameters define the interface characteristics that the adapters do not affect directly.

### *Channel Signal Width (Bits)*

Set the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is eight bits. Set to 0 if channels are not used.

### *Max Channel*

Set the maximum number of channels that the interface supports. Valid values are 0 - 255.

### *Bits Per Symbol*

Set the number of bits per symbol.

### *Symbols Per Beat*

Record the number of symbols per active transfer.

### *Include Packet Support*

Check this box if the interfaces supports a packet protocol, including the `startofpacket`, `endofpacket` and `empty` signals.

### *Error Signal Width (Bits)*

Record the width of the `error` signal. Valid values are 0–31 bits. Set to 0 if the `error` signal is not used.

## **Data Format Adapter**

The data format adapter handles interfaces that have different definitions for the `data` signal. One of the more common adaptations that this adapter performs is bus width adaptation, such as converting a data

interface that drives two, 8-bit symbols per beat to an interface that drives four, 8-bit symbols per beat. The available data format adaptations are listed in [Table 11-3](#).

<b>Condition</b>	<b>Description of Adapter Logic</b>
The source and sink's bits per symbol are different.	The connection cannot be made.
The source and sink have a different number of symbols per beat.	<p>The adapter converts from the source's width to the sink's width.</p> <p>If the adaptation is from a wider to a narrower interface, a beat of data at the input will correspond to multiple beats of data at the output. If the input <code>error</code> signal is asserted for a single beat, it is asserted on output for multiple beats.</p> <p>If the adaptation is from a narrow to a wider interface, multiple input beats are required to fill a single output beat, and the output <code>error</code> is the logical OR of the input <code>error</code> signal.</p>

## Resource Usage and Performance

Resource utilization for the data format adapter depends upon the function that it performs. [Table 11-4](#) provides estimated resource utilization for numerous configurations of the data format adapter.

**Table 11–4. Data Format Adapter Estimated Resource Usage and Performance, 8 Bits per Symbol**

Input Symbols per Beat	Output Symbols per Beat	Number of Channels	Packet Support	Stratix®II and Stratix II GX (Approximate LEs)			Cyclone® II			Stratix (Approximate LEs)		
				f <sub>MAX</sub> (MHz)	ALM Count	Mem Bits	f <sub>MAX</sub> (MHz)	Logic Cells	Memory Bits	f <sub>MAX</sub> (MHz)	Logic Cells	Mem Bits
1	2	1	y	500	96	0	391	93	0	375	105	0
4	1	1	y	459	106	0	311	97	0	306	76	0
4	2	1	y	500	118	0	343	107	0	326	85	0
4	8	1	y	437	326	0	346	370	0	303	330	0
4	16	1	y	357	930	0	264	1005	0	231	806	0

## Instantiating the Data Format Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. This section describes the options available on the **Parameter Settings** page of the configuration wizard.

### Input Interface Parameters

#### *Data Symbols Per Beat*

Set the number of symbols transferred per active cycle.

### Output Interface Parameters

#### *Data Symbols Per Beat*

Set the number of symbols transferred per active cycle. This value can be different for the input and output interfaces.

### Common to Input and Output

The following parameters define the interface characteristics that the adapters do not affect directly.

#### *Support Backpressure with the Ready Signal*

This option adds the backpressure functionality to the interface. When the ready signal is used, the value for `READY_LATENCY` indicates the number of cycles between when the ready signal is asserted and when valid data is driven.

#### *Data Bits Per Symbol*

Record the number of bits per symbol. This value must be the same for the input and output interfaces.

#### *Channel Signal Width (Bits)*

Record the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is 8 bits. Set to 0 if channels are not used.

#### *Max Channel*

Record the maximum number of channels that the interface supports. Valid values are 0 – 255.

### *Include Packet Support*

Turn this option on if the interface supports a packet protocol, including the `startofpacket`, `endofpacket`, and `empty` signals.

### *Error Signal Width (Bits)*

Record the width of the `error` signal. Valid values are 0–31 bits. Set to 0 if the `error` signal is not used.

## Channel Adapter

The channel adapter provides adaptations between interfaces that have different support for the `channel` signal or for the maximum number of channels supported. The adaptations are described in [Table 11–5](#).

<b>Condition</b>	<b>Description of Adapter Logic</b>
The source uses channels, but the sink does not.	The adapter provides a simulation error and signals an error for data for any channel from the source other than 0. A warning is provided to the user at generation time.
The sink has channel, but the source does not.	The user is presented with a warning, and the channel inputs to the sink are all tied to 0.
The source and sink both support channels, and the source's maximum number of channels is less than the sink's.	The source's channel is connected to the sink's channel unchanged. If the sink's channel signal has more bits, the higher bits are tied to 0.
The source and sink both support channels, but the source's maximum number of channels is greater than the sink's.	<p>The source's channel is connected to the sink's channel unchanged. If the source's channel signal has more bits, the higher bits are left unconnected. The user is presented with a warning that channel information may be lost.</p> <p>An adapter provides a simulation error message and an error indication if the value of channel from the source is greater than the sink's maximum number of channels. In addition, the <code>valid</code> signal to the sink is deasserted so that the sink never sees data for channels that are out of range.</p>

## Resource Usage and Performance

The channel adapter uses fewer than 30 LEs. Its frequency is limited by the maximum frequency of the chosen device.

## Instantiating the Channel Adapter in SOPC Builder

You can use the Avalon-ST configuration wizard in SOPC Builder to specify the hardware features. This section describes the options available on the **Parameter Settings** page of the configuration wizard.

### Input Interface Parameters

#### *Channel Signal Width (Bits)*

Set the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is 8 bits. Set to 0 if channels are not used.

#### *Max Channel*

Set the maximum number of channels that the interface supports. Valid values are 0 – 255.

### Output Interface Parameters

#### *Channel Signal Width (Bits)*

Record the width of the `channel` signal. A channel width of 4 allows up to 16 channels. The maximum width of the `channel` signal is 8 bits. Set to 0 if channels are not used.

#### *Max Channel*

Set the maximum number of channels that the interface supports. Valid values are 0 – 255.

### Common to Input and Output Interfaces

**Support Backpressure with the Ready Signal**—Turn this option on to add the backpressure functionality to the interface. When the `ready` signal is used, the value for `READY_LATENCY` indicates the number of cycles between when the `ready` signal is asserted and when valid data is driven.

#### *Data Bits Per Symbol*

Set the number of bits per symbol.

### *Symbols Per Beat*

Set the number of symbols per active cycle.

### *Include Packet Support*

Turn this option on if the interface supports a packet protocol, including the `startofpacket`, `endofpacket` and empty signals.

### *Error Signal Width (Bits)*

Set the width of the `error` signal. Valid values are 0–31 bits. Set to 0 if the `error` signal is not used.

## Device Support

Altera device support for the Avalon-ST interconnect components is listed in [Table 11–6](#). For each device family, a component provides either full or preliminary support:

- *Full support* means the component meets all functional and timing requirements for the device family and may be used in production designs.
- *Preliminary support* means the component meets all functional requirements, but might still be undergoing timing analysis for the device family; it may be used in production designs with caution.

**Table 11–6. Device Family Support**

Device Family	Timing Adapter	Data Format Adapter	Channel Adapter
Arria GX™	preliminary support	preliminary support	preliminary support
Stratix® III	preliminary support	preliminary support	preliminary support
Stratix II GX	preliminary support	preliminary support	preliminary support
Stratix II	preliminary support	preliminary support	preliminary support
Stratix	preliminary support	preliminary support	preliminary support
Cyclone III®	preliminary support	preliminary support	preliminary support
Cyclone II	preliminary support	preliminary support	preliminary support
Cyclone	preliminary support	preliminary support	preliminary support
Hardcopy® II	preliminary support	preliminary support	preliminary support

## Installation and Licensing

The Avalon-ST interconnect components are included in the Altera MegaCore IP Library, which is an optional part of the Quartus® II software installation. After you install the MegaCore IP Library, SOPC Builder recognizes these components and can instantiate them into a system.

You can use the Avalon-ST components without a license in any design targeting an Altera device.

## Hardware Simulation Considerations

The Avalon-ST interconnect components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

## Software Programming Model

The Avalon-ST interconnect components do not have any user-visible control or status registers. Therefore, software cannot control or configure any aspect of the interconnect components at run-time. These components cannot generate interrupts.

Document Revision History .....	7-14

## Section II. Communication Peripherals

### Chapter 8. JTAG UART Core

Core Overview .....	8-1
Functional Description .....	8-2
Avalon Slave Interface and Registers .....	8-2
Read and Write FIFOs .....	8-3
JTAG Interface .....	8-3
Host-Target Connection .....	8-3
Device and Tools Support .....	8-4
Instantiating the Core in SOPC Builder .....	8-4
Configuration Page .....	8-4
Write FIFO Settings .....	8-5
Read FIFO Settings .....	8-5
Simulation Settings .....	8-6
Simulated Input Character Stream .....	8-6
Prepare Interactive Windows .....	8-6
Hardware Simulation Considerations .....	8-7
Software Programming Model .....	8-7
HAL System Library Support .....	8-7
Driver Options: Fast versus Small Implementations .....	8-9
ioctl() Operations .....	8-10
Software Files .....	8-11
Accessing the JTAG UART Core via a Host PC .....	8-11
Register Map .....	8-11
Data Register .....	8-12
Control Register .....	8-13
Interrupt Behavior .....	8-13
Referenced Document .....	8-14
Document Revision History .....	8-15

### Chapter 9. UART Core

Core Overview .....	9-1
Functional Description .....	9-2
Avalon-MM Slave Interface and Registers .....	9-2
RS-232 Interface .....	9-3
Transmitter Logic .....	9-3
Receiver Logic .....	9-4
Baud Rate Generation .....	9-4
Device and Tools Support .....	9-4
Instantiating the Core in SOPC Builder .....	9-5
Configuration Settings .....	9-5
Baud Rate Options .....	9-5
Baud Rate (bps) Setting .....	9-5
Baud Rate Can Be Changed By Software Setting .....	9-6
Data Bits, Stop Bits, Parity .....	9-6

Data Bits Setting .....	9-6
Parity Setting .....	9-6
Flow Control .....	9-7
Include CTS/RTS Pins and Control Register Bits .....	9-7
Avalon-MM Transfers with Flow Control (DMA) .....	9-7
Include End-of-Packet Register .....	9-7
Simulation Settings .....	9-8
Simulated RXD-Input Character Stream .....	9-8
Prepare Interactive Windows .....	9-8
Create ModelSim Alias to Open Streaming Output Window .....	9-8
Create ModelSim Alias to Open Interactive Stimulus Window .....	9-8
Simulated Transmitter Baud Rate .....	9-9
Hardware Simulation Considerations .....	9-9
Software Programming Model .....	9-9
HAL System Library Support .....	9-10
Driver Options: Fast Versus Small Implementations .....	9-11
ioctl() Operations .....	9-12
Limitations .....	9-13
Software Files .....	9-13
Legacy SDK Routines .....	9-13
Register Map .....	9-14
rxdata Register .....	9-15
txdata Register .....	9-15
status Register .....	9-15
control Register .....	9-18
divisor Register (Optional) .....	9-19
endofpacket Register (Optional) .....	9-20
Interrupt Behavior .....	9-20
Referenced Documents .....	9-21
Document Revision History .....	9-22

## Chapter 10. SPI Core

Core Overview .....	10-1
Functional Description .....	10-1
Example Configurations .....	10-2
Transmitter Logic .....	10-4
Receiver Logic .....	10-4
Master and Slave Modes .....	10-4
Master Mode Operation .....	10-5
Slave Mode Operation .....	10-6
Multi-Slave Environments .....	10-6
Avalon-MM Interface .....	10-7
Instantiating the SPI Core in SOPC Builder .....	10-7
Master/Slave Settings .....	10-7
Generate Select Signals .....	10-7
SPI Clock (sclk) Rate .....	10-8
Specify Delay .....	10-8

Data Register Settings .....	10-9
Timing Settings .....	10-9
Device and Tools Support .....	10-10
Software Programming Model .....	10-10
Hardware Access Routines .....	10-10
Software Files .....	10-12
Legacy SDK Routines .....	10-12
Register Map .....	10-12
rxdata Register .....	10-13
txdata Register .....	10-13
status Register .....	10-13
control Register .....	10-14
slaveselect Register .....	10-15
Referenced Document .....	10-15
Document Revision History .....	10-16

## Section III. Display Peripherals

### Chapter 11. Optrex 16207 LCD Controller Core

Core Overview .....	11-1
Functional Description .....	11-1
Device and Tools Support .....	11-2
Instantiating the Core in SOPC Builder .....	11-2
Software Programming Model .....	11-2
HAL System Library Support .....	11-2
Displaying Characters on the LCD .....	11-3
Software Files .....	11-4
Register Map .....	11-4
Interrupt Behavior .....	11-4
Referenced Document .....	11-4
Document Revision History .....	11-5

### Chapter 12. Video Sync Generator and Pixel Converter Cores

Core Overview .....	12-1
Video Sync Generator .....	12-2
Functional Description .....	12-2
Instantiating the Core in SOPC Builder .....	12-3
Signals .....	12-3
Timing Diagrams .....	12-4
Pixel Converter .....	12-5
Functional Description .....	12-5
Instantiating the Core in SOPC Builder .....	12-6
Signals .....	12-6
Device and Tools Support .....	12-6
Hardware Simulation Considerations .....	12-7

Referenced Document .....	12-7
Document Revision History .....	12-7

## Section IV. Multiprocessor Coordination Peripherals

### Chapter 13. Mutex Core

Core Overview .....	13-1
Functional Description .....	13-1
Device and Tools Support .....	13-2
Instantiating the Core in SOPC Builder .....	13-2
Software Programming Model .....	13-2
Software Files .....	13-3
Hardware Mutex .....	13-3
Mutex API .....	13-4
Document Revision History .....	13-11

### Chapter 14. Mailbox Core

Core Overview .....	14-1
Functional Description .....	14-1
Device and Tools Support .....	14-2
Instantiating the Core in SOPC Builder .....	14-2
Software Programming Model .....	14-3
Software Files .....	14-4
Programming with the Mailbox Core .....	14-4
Mailbox API .....	14-6
Referenced Document .....	14-12
Document Revision History .....	14-12

## Section V. Other Memory-Mapped Peripherals

### Chapter 15. PIO Core

Core Overview .....	15-1
Functional Description .....	15-1
Data Input and Output .....	15-2
Edge Capture .....	15-3
IRQ Generation .....	15-3
Example Configurations .....	15-4
Avalon-MM Interface .....	15-4
Instantiating the PIO Core in SOPC Builder .....	15-5
Basic Settings .....	15-5
Input Options .....	15-5
Edge Capture Register .....	15-5
Synchronously Capture .....	15-5

Enable Bit Clearing for Edge Capture Register .....	15-6
Interrupt .....	15-6
Device and Tools Support .....	15-6
Software Programming Model .....	15-6
Software Files .....	15-7
Legacy SDK Routines .....	15-7
Register Map .....	15-7
data Register .....	15-7
direction Register .....	15-8
interruptmask Register .....	15-8
edgcapture Register .....	15-8
Interrupt Behavior .....	15-9
Software Files .....	15-9

# Chapter Revision Dates

The chapters in this book, *Quartus II Handbook, Volume 5*, were revised on the following dates. Where chapters or groups of chapters are available separately, part numbers are listed.

- Chapter 1. SDRAM Controller Core
  - Revised: *October 2007*
  - Part number: *NII51005-7.2.0*
  
- Chapter 2. CompactFlash Core
  - Revised: *October 2007*
  - Part number: *QII55005-7.2.0*
  
- Chapter 3. Common Flash Interface Controller Core
  - Revised: *October 2007*
  - Part number: *NII51013-7.2.0*
  
- Chapter 4. EPCS Device Controller Core
  - Revised: *October 2007*
  - Part number: *NII51012-7.2.0*
  
- Chapter 5. On-Chip FIFO Memory Core
  - Revised: *October 2007*
  - Part number: *QII55002-7.2.0*
  
- Chapter 6. Scatter-Gather DMA Controller Core
  - Revised: *October 2007*
  - Part number: *QII55003-7.2.0*
  
- Chapter 7. DMA Controller Core
  - Revised: *October 2007*
  - Part number: *NII51006-7.2.0*
  
- Chapter 8. JTAG UART Core
  - Revised: *October 2007*
  - Part number: *NII51009-7.2.0*
  
- Chapter 9. UART Core
  - Revised: *October 2007*
  - Part number: *NII51010-7.2.0*

- Chapter 10. SPI Core  
Revised: *October 2007*  
Part number: *NII51011-7.2.0*
- Chapter 11. Optrex 16207 LCD Controller Core  
Revised: *October 2007*  
Part number: *NII51019-7.2.0*
- Chapter 12. Video Sync Generator and Pixel Converter Cores  
Revised: *October 2007*  
Part number: *QII55006-7.2.0*
- Chapter 13. Mutex Core  
Revised: *October 2007*  
Part number: *NII51020-7.2.0*
- Chapter 14. Mailbox Core  
Revised: *October 2007*  
Part number: *NII53001-7.2.0*
- Chapter 15. PIO Core  
Revised: *October 2007*  
Part number: *NII51007-7.2.0*
- Chapter 16. Timer Core  
Revised: *October 2007*  
Part number: *NII51008-7.2.0*
- Chapter 17. System ID Core  
Revised: *October 2007*  
Part number: *NII51014-7.2.0*
- Chapter 18. PLL Core  
Revised: *October 2007*  
Part number: *NII53002-7.2.0*
- Chapter 19. Performance Counter Core  
Revised: *October 2007*  
Part number: *QII55001-7.2.0*
- Chapter 20. Avalon Streaming Channel Multiplexer and Demultiplexer Cores  
Revised: *October 2007*  
Part number: *QII55004-7.2.0*
- Chapter 21. Avalon Streaming Test Pattern Generator and Checker Cores  
Revised: *October 2007*  
Part number: *QII55007-7.2.0*

# About This Handbook

## Introduction

This volume describes intellectual property (IP) cores provided by Altera® for embedded systems design. These cores are installed with the Quartus® II software, and you can use them free of charge in Altera devices. Each core is SOPC Builder ready and can be instantiated in any SOPC Builder system. Most cores provide software driver support for the Altera Nios® II processor, and work seamlessly in Nios II systems.

Each chapter provides complete reference for a core, including the following information:

- Hardware structure
- Features and interface(s) to the core
- Available options when instantiating the core in SOPC Builder
- Hardware simulation considerations, if any
- Software programming model, including a description of the registers and driver functions.
- Device and tools support

## How to Contact Altera

For the most up-to-date information about Altera products, see the following table.

Contact (1)	Contact Method	Address
Technical support	Website	<a href="http://www.altera.com/support">www.altera.com/support</a>
Technical training	Website	<a href="http://www.altera.com/training">www.altera.com/training</a>
	Email	<a href="mailto:custrain@altera.com">custrain@altera.com</a>
Product literature	Website	<a href="http://www.altera.com/literature">www.altera.com/literature</a>
Altera literature services	Email	<a href="mailto:literature@altera.com">literature@altera.com</a>
Non-technical support (General) (Software Licensing)	Email	<a href="mailto:nacomp@altera.com">nacomp@altera.com</a>
	Email	<a href="mailto:authorization@altera.com">authorization@altera.com</a>

**Note to table:**

(1) You can also contact your local Altera sales office or sales representative.

# Typographic Conventions

This document uses the typographic conventions shown in the following table.

Visual Cue	Meaning
<b>Bold Type with Initial Capital Letters</b>	Command names, dialog box titles, checkbox options, and dialog box options are shown in bold, initial capital letters. Example: <b>Save As</b> dialog box.
<b>bold type</b>	External timing parameters, directory names, project names, disk drive names, filenames, filename extensions, and software utility names are shown in bold type. Examples: <b>f<sub>MAX</sub></b> , <b>qdesigns</b> directory, <b>d:</b> drive, <b>chiptrip.gdf</b> file.
<i>Italic Type with Initial Capital Letters</i>	Document titles are shown in italic type with initial capital letters. Example: <i>AN 75: High-Speed Board Design</i> .
<i>Italic type</i>	Internal timing parameters and variables are shown in italic type. Examples: <i>t<sub>PIA</sub></i> , <i>n + 1</i> .  Variable names are enclosed in angle brackets (< >) and shown in italic type. Example: <file name>, <project name>.pof file.
Initial Capital Letters	Keyboard keys and menu names are shown with initial capital letters. Examples: Delete key, the Options menu.
“Subheading Title”	References to sections within a document and titles of on-line help topics are shown in quotation marks. Example: “Typographic Conventions.”
Courier type	Signal and port names are shown in lowercase Courier type. Examples: data1, tdi, input. Active-low signals are denoted by suffix n, e.g., resetn.  Anything that must be typed exactly as it appears is shown in Courier type. For example: c:\qdesigns\tutorial\chiptrip.gdf. Also, sections of an actual file, such as a Report File, references to parts of files (e.g., the AHDL keyword SUBDESIGN), as well as logic function names (e.g., TRI) are shown in Courier.
1., 2., 3., and a., b., c., etc.	Numbered steps are used in a list of items when the sequence of the items is important, such as the steps listed in a procedure.
	Bullets are used in a list of items when the sequence of the items is not important.
	The checkmark indicates a procedure that consists of one step only.
	The hand points to information that requires special attention.
	A caution calls attention to a condition or possible situation that can damage or destroy the product or the user's work.
	A warning calls attention to a condition or possible situation that can cause injury to the user.
	The angled arrow indicates you should press the Enter key.
	The feet direct you to more information about a particular topic.

This section describes memory components and interfaces provided by Altera®. These components provide access to on-chip or off-chip memory for SOPC Builder systems.

See *About This Handbook* for further details.

This section includes the following chapters:

- Chapter 1, SDRAM Controller Core
- Chapter 2, CompactFlash Core
- Chapter 3, Common Flash Interface Controller Core
- Chapter 4, EPCS Device Controller Core
- Chapter 5, On-Chip FIFO Memory Core
- Chapter 6, Scatter-Gather DMA Controller Core
- Chapter 7, DMA Controller Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Core Overview

The SDRAM controller core with Avalon<sup>®</sup> interface provides an Avalon Memory-Mapped (Avalon-MM) interface to off-chip SDRAM. The SDRAM controller allows designers to create custom systems in an Altera<sup>®</sup> FPGA that connect easily to SDRAM chips. The SDRAM controller supports standard SDRAM as described in the PC100 specification.

SDRAM is commonly used in cost-sensitive applications requiring large amounts of volatile memory. While SDRAM is relatively inexpensive, control logic is required to perform refresh operations, open-row management, and other delays and command sequences. The SDRAM controller connects to one or more SDRAM chips, and handles all SDRAM protocol requirements. Internal to the FPGA, the core presents an Avalon-MM slave port that appears as linear memory (that is, flat address space) to Avalon-MM master peripherals.

The core can access SDRAM subsystems with various data widths (8, 16, 32, or 64 bits), various memory sizes, and multiple chip selects. The Avalon-MM interface is latency-aware, allowing read transfers to be pipelined. The core can optionally share its address and data buses with other off-chip Avalon-MM tri-state devices. This feature is valuable in systems that have limited I/O pins, yet must connect to multiple memory chips in addition to SDRAM.

The SDRAM controller core with Avalon interface is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [“Functional Description” on page 1-2](#)
- [“Device and Tools Support” on page 1-6](#)
- [“Instantiating the Core in SOPC Builder” on page 1-6](#)
- [“Hardware Simulation Considerations” on page 1-9](#)
- [“Software Programming Model” on page 1-13](#)
- [“Clock, PLL and Timing Considerations” on page 1-13](#)

## Functional Description

Figure 1-1 shows a block diagram of the SDRAM controller core connected to an external SDRAM chip.

**Figure 1-1. SDRAM Controller with Avalon Interface Block Diagram**

The following sections describe the components of the SDRAM controller core in detail. All options are specified at system generation time, and cannot be changed at runtime.

### Avalon-MM Interface

The Avalon-MM slave port is the user-visible part of the SDRAM controller core. The slave port presents a flat, contiguous memory space as large as the SDRAM chip(s). When accessing the slave port, the details of the PC100 SDRAM protocol are entirely transparent. The Avalon-MM interface behaves as a simple memory interface. There are no memory-mapped configuration registers.

The Avalon-MM slave port supports peripheral-controlled wait states for read and write transfers. The slave port stalls the transfer until it can present valid data. The slave port also supports read transfers with variable latency, enabling high-bandwidth, pipelined read transfers. When a master peripheral reads sequential addresses from the slave port, the first data returns after an initial period of latency. Subsequent reads

can produce new data every clock cycle. However, data is not guaranteed to return every clock cycle, because the SDRAM controller must pause periodically to refresh the SDRAM.

For details about Avalon-MM transfer types, refer to the *Avalon Memory-Mapped Interface Specification*.

## Off-Chip SDRAM Interface

The interface to the external SDRAM chip presents the signals defined by the PC100 standard. These signals must be connected externally to the SDRAM chip(s) through I/O pins on the Altera FPGA.

### *Signal Timing and Electrical Characteristics*

The timing and sequencing of signals depends on the configuration of the core. The hardware designer configures the core to match the SDRAM chip chosen for the system. See [“Instantiating the Core in SOPC Builder” on page 1–6](#) for details. The electrical characteristics of the FPGA pins depend on both the target device family and the assignments made in the Quartus® II software. Some FPGA families support a wider range of electrical standards, and therefore are capable of interfacing with a greater variety of SDRAM chips. For details, see the handbook for the target FPGA family.

### *Synchronizing Clock and Data Signals*

The clock for the SDRAM chip (hereafter "SDRAM clock") must be driven at the same frequency as the clock for the Avalon-MM interface on the SDRAM controller (hereafter "controller clock"). As in all synchronous design, you must ensure that address, data, and control signals at the SDRAM pins are stable when a clock edge arrives. As shown in [Figure 1–1](#), you can use an on-chip phase-locked loop (PLL) to alleviate clock skew between the SDRAM controller core and the SDRAM chip. At lower clock speeds, the PLL might not be necessary. At higher clock rates, a PLL is necessary to ensure that the SDRAM clock toggles only when signals are stable on the pins. The PLL block is not part of the SDRAM controller core. If a PLL is necessary, you must instantiate it manually. You can instantiate the PLL core interface, which is an SOPC Builder component, or instantiate an `altpll` megafunction outside the SOPC Builder system module.

If you use a PLL, you must tune the PLL to introduce a clock phase shift so that SDRAM clock edges arrive after synchronous signals have stabilized. See [“Clock, PLL and Timing Considerations” on page 1–13](#) for details.

For more information about instantiating a PLL in your SOPC Builder system, refer to the *PLL Core* chapter in volume 5 of the *Quartus II Handbook*. The Nios® II development tools provide example hardware designs that use the SDRAM controller core in conjunction with a PLL, which you can use as a reference for your custom designs. The Nios II development tools are available free for download from [www.altera.com](http://www.altera.com).

### *Clock Enable (CKE) Not Supported*

The SDRAM controller does not support clock-disable modes. The SDRAM controller permanently asserts the CKE signal on the SDRAM.

### *Sharing Pins with Other Avalon-MM Tri-State Devices*

If an Avalon-MM tri-state bridge is present in the SOPC Builder system, the SDRAM controller core can share pins with the existing tri-state bridge. In this case, the core's `addr`, `dq` (data) and `dqm` (byte-enable) pins are shared with other devices connected to the Avalon-MM tri-state bridge. This feature conserves I/O pins, which is valuable in systems that have multiple external memory chips (for example, flash, SRAM, and SDRAM), but too few pins to dedicate to the SDRAM chip. See “[Performance Considerations](#)” for details about how pin sharing affects performance.

The SDRAM addresses must connect all address bits regardless of the size of the word so that the low-order address bits on the tri-state bridge align with the low-order address bits on the memory device. It is not possible to drop A0 for memories when the smallest access size is 16 bits or A0-A1 when the smallest access size is 32 bits.

## **Board Layout and Pinout Considerations**

When making decisions about the board layout and FPGA pinout, try to minimize the skew between the SDRAM signals. For example, when assigning the FPGA pinout, group the SDRAM signals, including the SDRAM clock output, physically close together. Also, you can use the **Fast Input Register** and **Fast Output Register** logic options in the Quartus II software. These logic options place registers for the SDRAM signals in the I/O cells. Signals driven from registers in I/O cells have similar timing characteristics, such as  $t_{CO}$ ,  $t_{SU}$ , and  $t_H$ .

## Performance Considerations

Under optimal conditions, the SDRAM controller core's bandwidth approaches one word per clock cycle. However, because of the overhead associated with refreshing the SDRAM, it is impossible to reach one word per clock cycle. Other factors affect the core's performance, as described below.

### *Open Row Management*

SDRAM chips are arranged as multiple banks of memory, in which each bank is capable of independent open-row address management. The SDRAM controller core takes advantage of open-row management for a single bank. Continuous reads or writes within the same row and bank operate at rates approaching one word per clock. Applications that frequently access different destination banks require extra management cycles for row closings and openings.

### *Sharing Data and Address Pins*

When the controller shares pins with other tri-state devices, average access time usually increases and bandwidth decreases. When access to the tri-state bridge is granted to other devices, the SDRAM requires row open and close overhead cycles. Furthermore, the SDRAM controller has to wait several clock cycles before it is granted access again.

To maximize bandwidth, the SDRAM controller automatically maintains control of the tri-state bridge as long as back-to-back read or write transactions continue within the same row and bank.

This behavior may degrade the average access time for other devices sharing the Avalon-MM tri-state bridge.

The SDRAM controller closes an open row whenever there is a break in back-to-back transactions, or whenever a refresh transaction is required. As a result:

- The controller cannot permanently block access to other devices sharing the tri-state bridge.
- The controller is guaranteed not to violate the SDRAM's row open time limit.

### *Hardware Design and Target FPGA*

The target FPGA affects the maximum achievable clock frequency of a hardware design. Certain device families achieve higher  $f_{MAX}$  performance than other families. Furthermore, within a device family

faster speed grades achieve higher performance. The SDRAM controller core can achieve 100 MHz in Altera's high-performance device families, such as Stratix® series FPGAs. However, the core might not achieve 100 MHz performance in all Altera FPGA families.

The  $f_{MAX}$  performance also depends on the SOPC Builder system design. The SDRAM controller clock can also drive other logic in the system module, which might affect the maximum achievable frequency. For the SDRAM controller core to achieve  $f_{MAX}$  performance of 100 MHz, all components driven by the same clock must be designed for a 100 MHz clock rate, and timing analysis in the Quartus II software must verify that the overall hardware design is capable of 100 MHz operation.

## Device and Tools Support

The SDRAM Controller with Avalon interface core supports all Altera FPGA families. Different FPGA families support different I/O standards, which may affect the ability of the core to interface to certain SDRAM chips. For details about supported I/O types, see the handbook for the target FPGA family.

## Instantiating the Core in SOPC Builder

Designers use the MegaWizard® Plug-In Manager interface for the SDRAM controller in SOPC Builder to specify hardware features and simulation features. The SDRAM controller MegaWizard interface has two pages: **Memory Profile** and **Timing**. This section describes the options available on each page.

The **Presets** list offers several pre-defined SDRAM configurations as a convenience. If the SDRAM subsystem on the target board matches one of the preset configurations, you can configure the SDRAM controller core easily by selecting the appropriate preset value. The following preset configurations are defined:

- Micron MT8LSDT1664HG module
- Four SDR100 8 MByte × 16 chips
- Single Micron MT48LC2M32B2-7 chip
- Single Micron MT48LC4M32B2-7 chip
- Single NEC D4564163-A80 chip (64 MByte × 16)
- Single Alliance AS4LC1M16S1-10 chip
- Single Alliance AS4LC2M8S0-10 chip

Selecting a preset configuration automatically changes values on the **Memory Profile** and **Timing** tabs to match the specific configuration. Altering a configuration setting on any page changes the **Preset** value to **custom**.

## Memory Profile Page

The **Memory Profile** page allows designers to specify the structure of the SDRAM subsystem, such as address and data bus widths, the number of chip select signals, and the number of banks. [Table 1–1](#) lists the settings available on the **Memory Profile** page.

<b>Table 1–1. Memory Profile Page Settings</b>				
<b>Settings</b>		<b>Allowed Values</b>	<b>Default Values</b>	<b>Description</b>
Data Width		8, 16, 32, 64	32	SDRAM data bus width. This value determines the width of the <code>dq</code> bus (data) and the <code>dqm</code> bus (byte-enable).
Architecture Settings	Chip Selects	1, 2, 4, 8	1	Number of independent chip selects in the SDRAM subsystem. By using multiple chip selects, the SDRAM controller can combine multiple SDRAM chips into one memory subsystem.
	Banks	2, 4	4	Number of SDRAM banks. This value determines the width of the <code>ba</code> bus (bank address) that connects to the SDRAM. The correct value is provided in the data sheet for the target SDRAM.
Address Width Settings	Row	11, 12, 13, 14	12	Number of row address bits. This value determines the width of the <code>addr</code> bus. The Row and Column values depend on the geometry of the chosen SDRAM. For example, an SDRAM organized as 4096 ( $2^{12}$ ) rows by 512 columns has a Row value of 12.
	Column	$\geq 8$ , and less than Row value	8	Number of column address bits. For example, the SDRAM organized as 4096 rows by 512 ( $2^9$ ) columns has a Column value of 9.
Share pins via tri-state bridge <code>dq/dqm/addr</code> I/O pins		checked (yes), unchecked (no)	No	When set to No, all pins are dedicated to the SDRAM chip. When set to Yes, the <code>addr</code> , <code>dq</code> , and <code>dqm</code> pins can be shared with a tristate bridge in the system. In this case, select the appropriate tristate bridge from the pulldown menu.
Include a functional memory model in the system testbench		Yes, No	Yes	When on, SOPC Builder creates a functional simulation model for the SDRAM chip. This default memory model accelerates the process of creating and verifying systems that use the SDRAM controller. See <a href="#">“Hardware Simulation Considerations” on page 1–9</a> .

Based on the settings entered on the **Memory Profile** page, the wizard displays the expected memory capacity of the SDRAM subsystem in units of megabytes, megabits, and number of addressable words. Compare these expected values to the actual size of the chosen SDRAM to verify that the settings are correct.

## Timing Page

The **Timing** page allows designers to enter the timing specifications of the SDRAM chip(s) used. The correct values are available in the manufacturer's data sheet for the target SDRAM. [Table 1-2](#) lists the settings available on the **Timing** page.

<i>Table 1-2. Timing Page Settings</i>			
Settings	Allowed Values	Default Value	Description
CAS latency	1, 2, 3	3	Latency (in clock cycles) from a read command to data out.
Initialization refresh cycles	1 – 8	2	This value specifies how many refresh cycles the SDRAM controller performs as part of the initialization sequence after reset.
Issue one refresh command every	—	15.625 $\mu$ s	This value specifies how often the SDRAM controller refreshes the SDRAM. A typical SDRAM requires 4,096 refresh commands every 64 ms, which can be achieved by issuing one refresh command every $64 \text{ ms} / 4,096 = 15.625 \mu\text{s}$ .
Delay after power up, before initialization	—	100 $\mu$ s	The delay from stable clock and power to SDRAM initialization.
Duration of refresh command ( $t_{rfc}$ )	—	70 ns	Auto Refresh period.
Duration of precharge command ( $t_{rp}$ )	—	20 ns	Precharge command period.
ACTIVE to READ or WRITE delay ( $t_{rcd}$ )	—	20 ns	ACTIVE to READ or WRITE delay.
Access time ( $t_{ac}$ )	—	17 ns	Access time from clock edge. This value may depend on CAS latency.
Write recovery time ( $t_{wr}$ , No auto precharge)	—	14 ns	Write recovery if explicit precharge commands are issued. This SDRAM controller always issues explicit precharge commands.

Regardless of the exact timing values you specify, the actual timing achieved for each parameter is an integer multiple of the Avalon clock period. For the **Issue one refresh command every** parameter, the actual timing is the greatest number of clock cycles that does not exceed the

target value. For all other parameters, the actual timing is the smallest number of clock ticks that provides a value greater than or equal to the target value.

## Hardware Simulation Considerations

This section discusses considerations for simulating systems with SDRAM. Three major components are required for simulation:

- A simulation model for the SDRAM controller
- A simulation model for the SDRAM chip(s), also called the memory model
- A simulation testbench that wires the memory model to the SDRAM controller pins.

Some or all of these components are generated by SOPC Builder at system generation time.

### SDRAM Controller Simulation Model

The SDRAM controller design files generated by SOPC Builder are suitable for both synthesis and simulation. Some simulation features are implemented in the HDL using “translate on/off” synthesis directives that make certain sections of HDL code invisible to the synthesis tool.

The simulation features are implemented primarily for easy simulation of Nios and Nios II processor systems using the ModelSim simulator. The SDRAM controller simulation model is not ModelSim specific. However, minor changes may be required to make the model work with other simulators.

If you change the simulation directives to create a custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precautions to ensure your changes are not overwritten.

For a demonstration of simulation of the SDRAM controller in the context of Nios II embedded processor systems, refer to *AN 351: Simulating Nios II Processor Designs*.

## SDRAM Memory Model

This section describes the two options for simulating a memory model of the SDRAM chip(s).

### *Using the Generic Memory Model*

If the **Include a functional memory model the system testbench** option is enabled at system generation, then SOPC Builder generates an HDL simulation model for the SDRAM memory. In the auto-generated system testbench, SOPC Builder automatically wires this memory model to the SDRAM controller pins.

Using the automatic memory model and testbench accelerates the process of creating and verifying systems that use the SDRAM controller. However, the memory model is a generic functional model that does not reflect the true timing or functionality of real SDRAM chips. The generic model is always structured as a single, monolithic block of memory. For example, even for a system that combines two SDRAM chips, the generic memory model is implemented as a single entity.

### *Using the SDRAM Manufacturer's Memory Model*

If the **Include a functional memory model the system testbench** option is not enabled, the designer is responsible for obtaining a memory model from the SDRAM manufacturer, and manually wiring the model to the SDRAM controller pins in the system testbench.

## Example Configurations

The following examples show how to connect the SDRAM controller outputs to an SDRAM chip or chips. The bus labeled `ctl` is an aggregate of the remaining signals, such as `cas_n`, `ras_n`, `cke` and `we_n`.

Figure 1–2 shows a single 128-Mbit SDRAM chip with 32-bit data. Address, data, and control signals are wired directly from the controller to the chip. The result is a 128-Mbit (16-Mbyte) memory space.

**Figure 1–2. Single 128-Mbit SDRAM Chip with 32-Bit Data**

Figure 1-3 shows two 64-Mbit SDRAM chips, each with 16-bit data. Address and control signals connect in parallel to both chips. Note that chipselect ( $cs\_n$ ) is shared by the chips. Each chip provides half of the 32-bit data bus. The result is a logical 128-Mbit (16-Mbyte) 32-bit data memory.

**Figure 1-3. Two 64-MBit SDRAM Chips Each with 16-Bit Data**

Figure 1–4 shows two 128-Mbit SDRAM chips, each with 32-bit data. Address, data, and control signals connect in parallel to the two chips. The chipselect bus ( $cs\_n[1:0]$ ) determines which chip is selected. The result is a logical 256-Mbit 32-bit wide memory.

**Figure 1–4. Two 128-Mbit SDRAM Chips Each with 32-Bit Data**

## Software Programming Model

The SDRAM controller behaves like simple memory when accessed via the Avalon-MM interface. There are no software-configurable settings, and there are no memory-mapped registers. No software driver routines are required for a processor to access the SDRAM controller.

## Clock, PLL and Timing Considerations

This section describes issues related to synchronizing signals from the SDRAM controller core with the clock that drives the SDRAM chip. During SDRAM transactions, the address, data, and control signals are valid at the SDRAM pins for a window of time, during which the SDRAM clock must toggle to capture the correct values. At slower clock frequencies, the clock naturally falls within the valid window. At higher frequencies, you must compensate the SDRAM clock to align with the valid window.

Determine when the valid window occurs either by calculation or by analyzing the SDRAM pins with an oscilloscope. Then use a PLL to adjust the phase of the SDRAM clock so that edges occur in the middle of the valid window. Tuning the PLL might require trial-and-error effort to align the phase shift to the properties of your target board.

For details about the PLL circuitry in your target device, refer to the appropriate device family handbook. For details about configuring the PLLs in Altera FPGAs, refer to the *altpll Megafunction User Guide*.

## Factors Affecting SDRAM Timing

The location and duration of the window depends on several factors:

- Timing parameters of the FPGA and SDRAM I/O pins — I/O timing parameters vary based on device family and speed grade.
- Pin location on the FPGA — FPGA I/O pins connected to row routing have different timing than pins connected to column routing.
- Logic options used during the Quartus II compilation — Logic options such as the **Fast Input Register** and **Fast Output Register** logic affect the design fit. The location of logic and registers inside the FPGA affects the propagation delays of signals to the I/O pins.
- SDRAM CAS latency

As a result, the valid window timing is different for different combinations of FPGA and SDRAM devices. Furthermore, the window depends on the Quartus II software fitting results and pin assignments.

## Symptoms of an Untuned PLL

Detecting when the PLL is not tuned correctly might be difficult. Data transfers to or from the SDRAM might not fail universally. For example, individual transfers to the SDRAM controller might succeed, whereas burst transfers fail. For processor-based systems, if software can perform read or write data to SDRAM, but cannot run when the code is located in SDRAM, then the PLL is probably tuned incorrectly.

## Estimating the Valid Signal Window

This section describes how to estimate the location and duration of the valid signal window using timing parameters provided in the SDRAM datasheet and the Quartus II software compilation report. After finding the window, tune the PLL so that SDRAM clock edges occur exactly in the middle of the window.

Calculating the window is a two-step process. First, determine by how much time the SDRAM clock can lag the controller clock, and then by how much time it can lead. After finding the maximum lag and lead values, calculate the midpoint between them.

These calculations provide an estimation only. The following delays can also affect proper PLL tuning, but are not accounted for by these calculations.

- Signal skew due to delays on the printed circuit board — These calculations assume zero skew.
- Delay from the PLL clock output nodes to destinations — These calculations assume that the delay from the PLL SDRAM-clock output-node to the pin is the same as the delay from the PLL controller-clock output-node to the clock inputs in the SDRAM controller. If these clock delays are significantly different, you must account for this phase shift in your window calculations.

Figure 1-5 shows how to calculate the maximum length of time that the SDRAM clock can lag the controller clock, and Figure 1-6 shows how to calculate the maximum lead. Lag is a negative time shift, relative to the controller clock, and lead is a positive time shift. The SDRAM clock can lag the controller clock by the lesser of the maximum lag for a read cycle or that for a write cycle. In other words,  $Maximum\ Lag = \text{minimum}(Read\ Lag, Write\ Lag)$ . Similarly, the SDRAM clock can lead by the lesser of the maximum lead for a read cycle or for a write cycle. In other words,  $Maximum\ Lead = \text{minimum}(Read\ Lead, Write\ Lead)$ .

Figure 1-5. Calculating the Maximum SDRAM Clock Lag

Figure 1–6. Calculating the Maximum SDRAM Clock Lead

### Example Calculation

This section demonstrates a calculation of the signal window for a Micron MT48LC4M32B2-7 SDRAM chip and an FPGA design targeting an Altera Stratix II EP2S60F672C5 FPGA. This example uses a CAS latency (CL) of 3 cycles, and a clock frequency of 50 MHz. All SDRAM signals on the FPGA are registered in I/O cells, enabled with the **Fast Input Register** and **Fast Output Register** logic options in the Quartus II software.

Table 1–3 shows the relevant timing parameters excerpted from the MT48LC4M32B2 device datasheet.

Parameter		Symbol	Value (ns) in -7 Speed Grade	
			Min.	Max.
Access time from CLK (pos. edge)	CL = 3	$t_{AC(3)}$		5.5
	CL = 2	$t_{AC(2)}$		8
	CL = 1	$t_{AC(1)}$		17
Address hold time		$t_{AH}$	1	
Address setup time		$t_{AS}$	2	
CLK high-level width		$t_{CH}$	2.75	
CLK low-level width		$t_{CL}$	2.75	
Clock cycle time	CL = 3	$t_{CK(3)}$	7	
	CL = 2	$t_{CK(2)}$	10	
	CL = 1	$t_{CK(1)}$	20	
CKE hold time		$t_{CKH}$	1	
CKE setup time		$t_{CKS}$	2	
CS#, RAS#, CAS#, WE#, DQM hold time		$t_{CMH}$	1	
CS#, RAS#, CAS#, WE#, DQM setup time		$t_{CMS}$	2	
Data-in hold time		$t_{DH}$	1	
Data-in setup time		$t_{DS}$	2	
Data-out high-impedance time	CL = 3	$t_{HZ(3)}$		5.5
	CL = 2	$t_{HZ(2)}$		8
	CL = 1	$t_{HZ(1)}$		17
Data-out low-impedance time		$t_{LZ}$	1	
Data-out hold time		$t_{OH}$	2.5	

Table 1–4 shows the relevant FPGA timing information, obtained from the Timing Analyzer section of the Quartus II Compilation Report. The values in Table 1–4 are the maximum or minimum values among all FPGA pins related to the SDRAM. The variance in timing between the SDRAM pins on the FPGA is small (less than 100 ps) because the registers for these signals are placed in the I/O cell.

**Table 1–4. FPGA I/O Timing Parameters**

Parameter	Symbol	Value (ns)
Clock period	$t_{CLK}$	20
Minimum clock-to-output time	$t_{CO\_MIN}$	2.399
Maximum clock-to-output time	$t_{CO\_MAX}$	2.477
Maximum hold time after clock	$t_{H\_MAX}$	–5.607
Maximum setup time before clock	$t_{SU\_MAX}$	5.936

You must compile the design in the Quartus II software to obtain the I/O timing information for the FPGA design. Although Altera device family datasheets contain generic I/O timing information for each device, the Quartus II Compilation Report provides the most precise timing information for your specific design.

The timing values found in the compilation report can change, depending on fitting, pin location, and other Quartus II logic settings. When you recompile the design in the Quartus II software, verify that the I/O timing has not changed significantly.

With the values from Tables 1–3 and Table 1–4 you can perform the calculations from Figures 1–5 and 1–6, as shown below.

The SDRAM clock can lag the controller clock by the lesser of *Read Lag* or *Write Lag*:

$$(1) \text{ Read Lag} = t_{OH}(\text{SDRAM}) - t_{H\_MAX}(\text{FPGA})$$

$$\text{Read Lag} = 2.5 \text{ ns} - (-5.607 \text{ ns})$$

$$\text{Read Lag} = 8.107 \text{ ns}$$

or

$$(2) \text{ Write Lag} = t_{CLK} - t_{CO\_MAX}(\text{FPGA}) - t_{DS}(\text{SDRAM})$$

$$\text{Write Lag} = 20 \text{ ns} - 2.477 \text{ ns}$$

Write Lag = 15.523 ns

The SDRAM clock can lead the controller clock by the lesser of *Read Lead* or *Write Lead*:

$$(3) \quad \text{Read Lead} = t_{\text{CO\_MIN}}(\text{FPGA}) - t_{\text{DH}}(\text{SDRAM})$$

$$\text{Read Lead} = 2.399 \text{ ns} - 1.0 \text{ ns}$$

$$\text{Read Lead} = 1.399 \text{ ns}$$

or

$$(4) \quad \text{Write Lead} = t_{\text{CLK} - t_{\text{HZ}(3)}}(\text{SDRAM}) - t_{\text{SU\_MAX}}(\text{FPGA})$$

$$\text{Write Lead} = 20 \text{ ns} - 5.5 \text{ ns} - 5.936 \text{ ns}$$

$$\text{Write Lead} = 8.564 \text{ ns}$$

Therefore, for this example you can shift the phase of the SDRAM clock from  $-8.107$  ns to  $1.399$  ns relative to the controller clock. Choosing a phase shift in the middle of this window results in the value  $(-8.107 + 1.399) \div 2 = -3.35$  ns .

### Core Overview

The CompactFlash core allows you to connect SOPC Builder systems to CompactFlash storage cards in true IDE mode by providing an Avalon Memory-Mapped (Avalon-MM) interface to the registers on the storage cards.

The CompactFlash core also provides a register-mapped Avalon-MM slave interface which can be used by Avalon-MM master peripherals such as a Nios II processor to communicate with the CompactFlash core and manage its operations.

The CompactFlash core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated systems.

This chapter contains the following sections:

- [“Functional Description” on page 2-2](#)
- [“Instantiating the Core in SOPC Builder” on page 2-3](#)
- [“Device and Tools Support” on page 2-4](#)
- [“Software Programming Model” on page 2-4](#)

## Functional Description

Figure 2-1 shows a block diagram of the CompactFlash core in a typical system configuration.

Figure 2-1. SOPC Builder System With a CompactFlash Core

As shown in Figure 2-1, the CompactFlash core provides two Avalon-MM slave interfaces: the `ide` slave port for accessing the registers on the CompactFlash device and the `ctl` slave port for accessing the core's internal registers. These registers can be used by Avalon-MM master peripherals such as a Nios II processor to control the operations of the CompactFlash core and to transfer data to and from the CompactFlash device.

You can set the CompactFlash core to generate two active-high interrupt requests (IRQs): one signals the insertion and removal of a CompactFlash device and the other passes interrupt signals from the CompactFlash device.

The CompactFlash core maps the Avalon-MM bus signals to the CompactFlash device with proper timing, thus allowing Avalon-MM master peripherals to directly access the registers on the CompactFlash device.

For more information, refer to the CF+ and CompactFlash specifications at [www.compactflash.org](http://www.compactflash.org).

## Instantiating the Core in SOPC Builder

Use the MegaWizard® Plug-In Manager interface for the CompactFlash core in SOPC Builder to add the core to a system. There are no user-configurable settings for this core.

## Required Connections

Table 2–1 lists the required connections between the CompactFlash core and the CompactFlash device.

**Table 2–1. Required Connections (Part 1 of 2)**

CompactFlash Interface Signal Name	Pin Type	CompactFlash Pin Number
addr [0]	Output	20
addr [1]	Output	19
addr [2]	Output	18
addr [3]	Output	17

## Device and Tools Support

The CompactFlash interface core supports all Altera FPGA families.

## Software Programming Model

This section describes the software programming model for the CompactFlash core.

### HAL System Library Support

The Altera-provided HAL API functions include a device driver that you can use to initialize the CompactFlash core. To perform other operations, use the low-level macros provided. For more information on the macros, refer to the files listed in the section [“Software Files” on page 2–5](#).

## Software Files

The CompactFlash core provides the following software files. These files define the low-level access to the hardware. Application developers should not modify these files.

- **altera\_avalon\_cf\_regs.h**—The header file that defines the core's register maps.
- **altera\_avalon\_cf.h, altera\_avalon\_cf.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.

## Register Maps

This section describes the register maps for the Avalon-MM slave interfaces.

### *Ide Registers*

The `ide` port in the CompactFlash core allows you to access the IDE registers on a CompactFlash device. [Table 2-2](#) shows the register map for the `ide` port.

Offset	Register Names	
	Read Operation	Write Operation
0	RD Data	WR Data
1	Error	Features
2	Sector Count	Sector Count
3	Sector No	Sector No
4	Cylinder Low	Cylinder Low
5	Cylinder High	Cylinder High
6	Select Card/Head	Select Card/Head
7	Status	Command
14	Alt Status	Device Control

### Ctl Registers

The `ctl` port in the CompactFlash core provides access to the registers which control the core's operation and interface. Table 2-3 shows the register map for the `ctl` port.

**Table 2-3. Ctl Register Map**

Offset	Register	Fields				
		31..4	3	2	1	0
0	<code>cfctl</code>	Reserved	IDET	RST	PWR	DET
1	<code>idectl</code>	Reserved				IIDE
2	Reserved	Reserved				
3	Reserved	Reserved				

### Cfctl Register

The `cfctl` register controls the operations of the CompactFlash core. Reading the `cfctl` register clears the interrupt. Table 2-4 describes the `cfctl` register bits.

**Table 2-4. cfctl Register Bits**

Bit Number	Bit Name	Read/Write	Description
0	DET	RO	Detect. This bit is set to 1 when the core detects a CompactFlash device.
1	PWR	RW	Power. When this bit is set to 1, power is being supplied to the CompactFlash device.
2	RST	RW	Reset. When this bit is set to 1, the CompactFlash device is held in a reset state. Setting this bit to 0 returns the device to its active state.
3	IDET	RW	Detect Interrupt Enable. When this bit is set to 1, the CompactFlash core generates an interrupt each time the value of the <code>det</code> bit changes.

**Idect1 Register**

The `idect1` register control the interface to the CompactFlash device.

[Table 2-5](#) describes the `idect1` register bit.

Bit Number	Bit Name	Read/Write	Description
0	IIDE	RW	IDE Interrupt Enable. When this bit is set to 1, the CompactFlash core generates an interrupt following an interrupt generated by the CompactFlash device. Setting this bit to 0 disables the IDE interrupt.

## Referenced Documents

## Document Revision History

[Table 2-6](#) shows the revision history for this chapter.

Date and Document Version	Changes Made	Summary of Changes
October 2007 v7.2.0	Initial release.	—

### Core Overview

The common flash interface controller core with Avalon<sup>®</sup> interface (CFI controller) allows you to easily connect SOPC Builder systems to external flash memory that complies with the Common Flash Interface (CFI) specification. The CFI controller is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system.

For the Nios<sup>®</sup> II processor, Altera provides hardware abstraction layer (HAL) driver routines for the CFI controller. The drivers provide universal access routines for CFI-compliant flash memories. Therefore, you do not need to write any additional code to program CFI-compliant flash devices. The HAL driver routines take advantage of the HAL generic device model for flash memory, which allows you to access the flash memory using the familiar HAL application programming interface (API) and/or the ANSI C standard library functions for file I/O. For details about how to read and write flash using the HAL API, refer to the *Nios II Software Developer's Handbook*.

The Nios II Embedded Design Suite (EDS) provides a flash programmer utility based on the Nios II processor and the CFI controller. The flash programmer utility can be used to program any CFI-compliant flash memory connected to an Altera<sup>®</sup> FPGA. For details, refer to the *Nios II Flash Programmer User Guide*.

Further information about the Common Flash Interface specification is available at [www.intel.com/design/flash/swb/cfi.htm](http://www.intel.com/design/flash/swb/cfi.htm). As an example of a flash device supported by the CFI controller, see the data sheet for the AMD Am29LV065D-120R, available at [www.amd.com](http://www.amd.com).

The common flash interface controller core supersedes previous Altera flash cores distributed with SOPC Builder or Nios development kits. All flash chips associated with these previous cores comply with the CFI specification, and therefore are supported by the CFI controller.

This chapter contains the following sections:

- “Functional Description” on page 3-2
- “Device and Tools Support” on page 3-2
- “Instantiating the Core in SOPC Builder” on page 3-3
- “Software Programming Model” on page 3-4

## Functional Description

Figure 3–1 shows a block diagram of the CFI controller in a typical system configuration. As shown in Figure 3–1, the Avalon-MM interface for flash devices is connected through an Avalon-MM tristate bridge. The tristate bridge creates an off-chip memory bus that allows the flash chip to share address and data pins with other memory chips. It provides separate chipselect, read, and write pins to each chip connected to the memory bus. The CFI controller hardware is minimal: It is simply an Avalon-MM tristate slave port configured with waitstates, setup, and hold time appropriate for the target flash chip. This slave port is capable of Avalon-MM tristate slave read and write transfers.

Figure 3–1. An SOPC Builder System Integrating a CFI Controller

Avalon-MM master ports can perform read transfers directly from the CFI controller’s Avalon-MM port. See “[Software Programming Model](#)” on page 3–4 for more detail on writing/erasing flash memory.

## Device and Tools Support

The CFI controller supports the Arria™ GX, Stratix® III, Stratix II GX, Stratix II, Stratix GX, Stratix, Cyclone® III, Cyclone II, and Cyclone device families. The CFI controller provides drivers for the Nios II HAL system library. No software support is provided for the first-generation Nios processor.

## Instantiating the Core in SOPC Builder

Hardware designers use the MegaWizard® interface for the CFI controller in SOPC Builder to specify the core features. The following sections describe the available options in the MegaWizard interface.

### Attributes Page

The options on this page control the basic hardware configuration of the CFI controller.

#### *Presets Settings*

The **Presets** setting is a drop-down menu of flash chips that have already been characterized for use with the CFI controller. After you select one of the chips in the **Presets** menu, the wizard updates all settings on both tabs (except for the Board Info setting) to work with the specified flash chip.

If the flash chip on your target board does not appear in the **Presets** list, you must configure the other settings manually.

#### *Size Settings*

The size setting specifies the size of the flash device. There are two settings:

- **Address Width**—The width of the flash chip's address bus.
- **Data Width**—The width of the flash chip's data bus

The size settings cause SOPC Builder to allocate the correct amount of address space for this device. SOPC Builder will automatically generate dynamic bus sizing logic that appropriately connects the flash chip to Avalon-MM master ports of different data widths. Refer to the *Avalon Memory-Mapped Interface Specification* for details about dynamic bus sizing.

### Timing Page

The options on this page specify the timing requirements for read and write transfers with the flash device. The settings available on the Timing page are:

- **Setup**—After asserting `chipselct`, the time required before asserting the read or write signals.
- **Wait**—The time required for the read or write signals to be asserted for each transfer.
- **Hold**—After deasserting the write signal, the time required before deasserting the `chipselct` signal.

- **Units**—The timing units used for the **Setup**, **Wait**, and **Hold** values. Possible values include ns, us, ms, and clock cycles.

For more information about signal timing for the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification*.

## Software Programming Model

This section describes the software programming model for the CFI controller. In general, any Avalon-MM master in the system can read the flash chip directly as a memory device. For Nios II processor users, Altera provides HAL system library drivers that enable you to erase and write the flash memory using the HAL API functions.

### HAL System Library Support

The Altera-provided driver implements a HAL flash device driver that integrates into the HAL system library for Nios II systems. Programs call the familiar HAL API functions to program CFI-compliant flash memory. You do not need to know anything about the details of the underlying drivers.

The HAL API for programming flash, including C code examples, is described in detail in the *Nios II Software Developer's Handbook*. The Nios II EDS also provides a reference design called Flash Tests that demonstrates erasing, writing, and reading flash memory.

### *Limitations*

Currently, the Altera-provided drivers for the CFI controller support only AMD and Intel flash chips.

### Software Files

The CFI controller provides the following software files. These files define the low-level access to the hardware, and provide the routines for the HAL flash device driver. Application developers should not modify these files.

- **altera\_avalon\_cfi\_flash.h, altera\_avalon\_cfi\_flash.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.
- **altera\_avalon\_cfi\_flash\_funcs.h, altera\_avalon\_cfi\_flash\_table.c**—The header and source code for functions concerned with accessing the CFI table.
- **altera\_avalon\_cfi\_flash\_amd\_funcs.h, altera\_avalon\_cfi\_flash\_amd.c**—The header and source code for programming AMD CFI-compliant flash chips.

- `altera_avalon_cfi_flash_intel_funcs.h`,  
`altera_avalon_cfi_flash_intel.c`—The header and source code for programming Intel CFI-compliant flash chips.

## Referenced Documents

This chapter references the following documents:

May 2004 v1.0	Initial release.	—

## Core Overview

The EPCS device controller core with Avalon® interface allows Nios® II systems to access an Altera® EPCS serial configuration device. Altera provides drivers that integrate into the Nios II hardware abstraction layer (HAL) system library, allowing you to read and write the EPCS device using the familiar HAL application program interface (API) for flash devices.

Using the EPCS controller, Nios II systems can:

- Store program code in the EPCS device. The EPCS controller provides a boot-loader feature that allows Nios II systems to store the main program code in an EPCS device.
- Store nonvolatile program data, such as a serial number, a NIC number, and other persistent data.
- Manage the FPGA configuration data. For example, a network-enabled embedded system can receive new FPGA configuration data over a network, and use the EPCS controller to program the new data into an EPCS serial configuration device.

The EPCS controller is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. The flash programmer utility in the Nios II IDE allows you to manage and program data contents into the EPCS device.

For information about the EPCS serial configuration device family, refer to the *Serial Configuration Devices (EPCS1 & EPCS4) Data Sheet*. For details about using the Nios II HAL API to read and write flash memory, refer to the *Nios II Software Developer's Handbook*. For details about managing and programming the EPCS memory contents, refer to the *Nios II Flash Programmer User Guide*.

For Nios II processor users, the EPCS controller core supersedes the Active Serial Memory Interface (ASMI) device. New designs should use the EPCS controller instead of the ASMI core.

## Functional Description

Figure 4-1 shows a block diagram of the EPCS controller in a typical system configuration. As shown in Figure 4-1, the EPCS device's memory can be thought of as two separate regions:

- *FPGA configuration memory*—FPGA configuration data is stored in this region.
- *General-purpose memory*—If the FPGA configuration data does not fill up the entire EPCS device, any left-over space can be used for general-purpose data and system startup code.

**Figure 4-1. Nios II System Integrating an EPCS Controller**

By virtue of the HAL generic device model for flash devices, accessing the EPCS device using the HAL API is the same as accessing any flash memory. The EPCS device has a special-purpose hardware interface, so Nios II programs must read and write the EPCS memory using the provided HAL flash drivers.

The EPCS controller core contains an on-chip memory for storing a boot-loader program. When used in conjunction with Cyclone®, Cyclone II, and Cyclone III devices, the core requires 512 bytes of boot-loader ROM. For Stratix® II and Stratix III devices, the core requires 1 Kbyte of boot-loader ROM. The Nios II processor can be configured to boot from the EPCS controller. To do so, set the Nios II reset address to the base address of the EPCS controller. In this case, after reset the CPU first executes code from the boot-loader ROM, which copies data from the

EPCS general-purpose memory region into a RAM. Then, program control transfers to the RAM. The Nios II IDE provides facilities to compile a program for storage in the EPCS device, and create a programming file to program into the EPCS device.

Refer to the *Nios II Flash Programmer User Guide*.

The Altera EPCS configuration device connects to the FPGA through dedicated pins on the FPGA, not through general-purpose I/O pins. In all Altera device families except Cyclone III, the EPCS controller core does not create any I/O ports on the top-level SOPC Builder system module. If the EPCS device and the FPGA are wired together on a board for configuration using the EPCS device (in other words, active serial configuration mode), no further connection is necessary between the EPCS controller and the EPCS device. When you compile the SOPC Builder system in the Quartus II software, the EPCS controller core signals are routed automatically to the device pins for the EPCS device.

If you program the EPCS device using the Quartus® II Programmer, all previous content is erased. To program the EPCS device with a combination of FPGA configuration data and Nios II program data, use the Nios II IDE flash programmer utility.

In Cyclone III, the EPCS controller does not automatically assign its output pins to the dedicated configuration pins on the FPGA. Instead, the output pins are exported to the top level design, giving users the flexibility to connect to any EPCS devices. For more information on the configuration pins in Cyclone III, refer to the [Pin-Out Files for Altera Device](#) page.

## Avalon-MM Slave Interface and Registers

The EPCS controller core has a single Avalon-MM slave interface that provides access to both boot-loader code and registers that control the core. As shown in [Table 4-1 on page 4-4](#), the first 256 words are dedicated to the boot-loader code, and the next seven words are control and data registers. A Nios II CPU can read 256 instruction words, starting from the EPCS controller's base address as flat memory space, which enables the CPU to reset into the EPCS controller's address space.

The EPCS controller core includes an interrupt signal that can be used to interrupt the CPU when a transfer has completed.

**Table 4–1. EPCS Controller Register Map**

Offset	Register Name	R/W	Bit Description
			31...0
0x000	Boot ROM Memory	R	Boot Loader Code
...			
0x0FF			
0x100	Read Data	R	(1)
0x101	Write Data	W	(1)
0x102	Status	R/W	(1)
0x103	Control	R/W	(1)
0x104	Reserved	—	(1)
0x105	Slave Enable	R/W	(1)
0x106	End of Packet	R/W	(1)

**Note to Table 4–1:**

- (1) Altera does not publish the usage of the control and data registers. To access the EPCS device, you must use the HAL drivers provided by Altera.

## Device and Tools Support

The EPCS controller supports all Altera FPGA families that support the EPCS configuration device, such as the Cyclone device family. The EPCS controller must be connected to a Nios II processor. The core provides drivers for HAL-based Nios II systems, and the precompiled boot loader code compatible with the Nios II processor. No software support is provided for any other processor, including the first-generation Nios.

## Instantiating the Core in SOPC Builder

Hardware designers use the EPCS controller’s SOPC Builder configuration wizard to add the EPCS controller to a system. There are no user-configurable settings for this component.

Only one EPCS controller can be instantiated in each FPGA design.

## Software Programming Model

This section describes the software programming model for the EPCS controller. Altera provides HAL system library drivers that enable you to erase and write the EPCS memory using the HAL API functions. Altera does not publish the usage of the cores registers. Therefore, you must use the HAL drivers provided by Altera to access the EPCS device.

## HAL System Library Support

The Altera-provided driver implements a HAL flash device driver that integrates into the HAL system library for Nios II systems. Programs call the familiar HAL API functions to program the EPCS memory. You do not need to know the details of the underlying drivers to use them.

The HAL API for programming flash, including C-code examples, is described in detail in the *Nios II Software Developer's Handbook*. For details about managing and programming the EPCS device contents, refer to the *Nios II Flash Programmer User Guide*.

## Software Files

The EPCS controller provides the following software files. These files provide low-level access to the hardware and drivers that integrate into the Nios II HAL system library. Application developers should not modify these files.

- **altera\_avalon\_epcs\_flash\_controller.h**, **altera\_avalon\_epcs\_flash\_controller.c**—Header and source files that define the drivers required for integration into the HAL system library.
- **epcs\_commands.h**, **epcs\_commands.c**—Header and source files that directly control the EPCS device hardware to read and write the device. These files also rely on the Altera SPI core drivers.

## Document Revision History

Table 4–2 shows the revision history for this chapter.

<b>Date and Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	<ul style="list-style-type: none"> <li>Chapter 4 was formerly Chapter 3.</li> <li>Added sentence stating that to boot from EPCS controller memory set Nios II reset address to the base address of the EPCS controller.</li> <li>Added description on output pins assignment for Cyclone III in the Functional Description section.</li> </ul>	—

## Core Overview

The on-chip FIFO memory core is a configurable component used to buffer data and provide flow control in an SOPC Builder system. The FIFO can operate with a single clock or with separate clocks for the input and output ports.

The input interface to the FIFO may be an Avalon® Memory Mapped (Avalon-MM) write slave or an Avalon Streaming (Avalon-ST) sink. The output interface can be a an Avalon-ST source or an Avalon-MM read slave. The data is delivered to the output interface in the same order that it was received at the input interface, regardless of the value of channel, packet, frame, or any other signals.

In single clock mode, the on-chip FIFO memory includes an optional status interface that provides information about the fill-level of the FIFO. In dual clock mode, separate, optional status interfaces can be included for the input and output interfaces. The status interface also includes registers to set and control interrupts.

The on-chip FIFO memory core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. Device drivers are provided in the HAL system library allowing software to access the core using ANSI C.

This chapter contains the following sections:

- [“Functional Description”](#)
- [“Device and Tools Support” on page 5–7](#)
- [“Instantiating the Core in SOPC Builder” on page 5–7](#)
- [“Software Programming Model” on page 5–9](#)
- [“Programming with the On-Chip FIFO Memory” on page 5–10](#)
- [“On-Chip FIFO Memory API” on page 5–17](#)

## Functional Description

The on-chip FIFO memory has four configurations:

- Avalon-MM write slave to Avalon-MM read slave
- Avalon-ST sink to Avalon-ST source
- Avalon-MM write slave to Avalon-ST source
- Avalon-ST sink to Avalon-MM read slave

In all configurations, the input and output interfaces can use the optional backpressure signals to prevent underflow and overflow conditions. For the Avalon-MM interface, backpressure is implemented using the `waitrequest` signal. For Avalon-ST interfaces, backpressure is implemented using the `ready` and `valid` signals. For the on-chip FIFO memory, the delay between the sink asserts `ready` and the source drives valid data is one cycle. Bursting to a FIFO is not supported.

### Avalon-MM Write Slave to Avalon-MM Read Slave

In this mode, the FIFO's input is a zero-address-width Avalon-MM write slave. An Avalon-MM write master pushes data into the FIFO by writing to the input interface, and a read master (possibly the same master) pops data by reading from its output interface. The FIFO's input and output data must be the same width.

If **Allow backpressure** is turned on, the `waitrequest` signal is asserted whenever the `data_in` master tries to write to a full FIFO. `waitrequest` is only deasserted when there is enough space in the FIFO for a new transaction to complete. `waitrequest` is asserted for read operations when there is no data to be read from the FIFO, and is deasserted when the FIFO has data.

**Figure 5–1. FIFO with Avalon-MM Input and Output Interfaces**

### Avalon-ST Sink to Avalon-ST Source

This FIFO has streaming input and output interfaces as illustrated in [Figure 5–2](#). You can parameterize most aspects of the Avalon-ST interfaces including the bits per symbol, symbols per beat, and the width of error and channel signals. The input and output interfaces must be

the same width. If **Allow backpressure** is on in the SOPC Builder MegaWizard, both interfaces use the `ready` and `valid` signals to indicate when space is available in the FIFO and when valid data is available.

For more information about the Avalon-ST interface protocol, refer to the *Avalon Streaming Interface Specification* available at [www.altera.com](http://www.altera.com).

**Figure 5–2. FIFO with Avalon-ST Input and Output Interfaces**

### Avalon-MM Write Slave to Avalon-ST Source

In this mode, the FIFO's input is an Avalon-MM write slave with a width of 32 bits as shown in [Figure 5–3](#). The Avalon-ST output (source) data width must also be 32 bits. You can configure output interface parameters, including: bits per symbol, symbols per beat, and the width of the channel and error signals. The FIFO performs the endian conversion to conform to the output interface protocol.

The signals that comprise this interface are mapped into bits in the Avalon's address space. If **Allow backpressure** is on, the input interface asserts `waitrequest` to indicate that the FIFO does not have enough space for the transaction to complete.

**Figure 5–3. FIFO with Avalon-MM Input Interface and Avalon-ST Output Interface**

The example memory map in [Table 5–1](#) illustrates the layout of memory for a FIFO with a 32-bit Avalon-MM input interface and an Avalon-ST output interface. The output interface has 8-bit symbols, a 5-bit channel signal, and a 3-bit error signal, with packet support.

**Table 5–1. Avalon-MM to Avalon-ST Memory Map**

Offset	31	24	23	19	18	16	15	13	12	8	7	4	3	2	1	0
base + 0	Symbol 3		Symbol 2			Symbol 1			Symbol 0							
base + 1	reserved		reserved	error	resrvd.	channel	reserved	empty	EOP	SOP						

If **Enable packet data** is off, the Avalon-MM write master writes all data at address offset 0 repeatedly to push data into the FIFO.

If **Enable packet data** is on, the Avalon-MM write master starts by writing the SOP, error (optional), channel (optional), EOP, and empty packet status information at address offset 1. Writing to address offset 1 does not push data into the FIFO. The Avalon-MM master then writes packet data to the FIFO repeatedly at address offset 0, pushing 8-bit symbols into the FIFO. Whenever a valid write occurs at address offset 0, the data and its respective packet information is pushed into the FIFO. Subsequent data is written at address offset 0 without the need to clear

the SOP. Rewriting to address offset 1 is not required each time if the subsequent data to be pushed into the FIFO is not the end-of-packet data, as long as `error` and `channel` do not change.

At the end of each packet, the Avalon-MM master writes to the address at offset 1 to set the EOP bit to 1, before writing the last symbol of the packet at offset 0. The write master uses the `empty` field to indicate the number of unused symbols at the end of the transfer. If the last packet data is not aligned with the symbols per beat, then the `empty` field indicates the number of empty symbols in the last packet data. For example, if the Avalon-ST interface has symbols-per-beat of 4, and the last packet only has 3 symbols, then the `empty` field will be 1, indicating that one symbol (the least significant symbol in the memory map) is empty.

### Avalon-ST Sink to Avalon-MM Read Slave

In this mode, the FIFO's input is an Avalon-ST sink and the output is an Avalon-MM read slave with a width of 32 bits (Figure 5-4). The Avalon-ST input (sink) data width must also be 32 bits. You can configure input interface parameters, including: bits per symbol, symbols per beat, and the width of the `channel` and `error` signals. The FIFO performs the endian conversion to conform to the output interface protocol.

An Avalon-MM master reads the data from the FIFO. The signals are mapped into bits in the Avalon's address space. If **Allow backpressure** is on in the SOPC Builder MegaWizard, the input (sink) interface uses the `ready` and `valid` signals to indicate when space is available in the FIFO and when valid data is available. For the output interface, `waitrequest` is asserted for read operations when there is no data to be read from the FIFO. It is deasserted when the FIFO has data to send.

**Figure 5–4. FIFO with Avalon-ST Input and Avalon-MM Output**

As shown in [Table 5–2](#), the memory map for the Avalon-ST to Avalon-MM slave FIFO is exactly the same as for Avalon-MM to Avalon-ST FIFO.

<b>Table 5–2. Avalon-ST to Avalon-MM Memory Map</b>																
Offset	31	24	23	19	18	16	15	13	12	8	7	4	3	2	1	0
base + 0	Symbol 3		Symbol 2			Symbol 1			Symbol 0							
base + 1	reserved		reserved	error	resrvd.	channel	reserved	empty							EOP	SOP

If **Enable packet data** is off, read data repeatedly at address offset 0 to pop the data from the FIFO.

If **Enable packet data** is on, the Avalon-MM read master starts reading from address offset 0. If the read is valid, that is, the FIFO is not empty, both data and packet status information are popped from the FIFO. The packet status information is obtained by reading at address offset 1. Reading from address offset 1 does not pop data from the FIFO. The `error`, `channel`, `SOP`, `EOP` and `empty` fields are available at address offset 1 to determine the status of the packet data read from address offset 0.

The `empty` field indicates the number of empty symbols in the data field. For example, if the Avalon-ST interface has symbols-per-beat of 4, and the last packet data only has 1 symbol, then the `empty` field will be 3 to indicate that 3 symbols (the 3 least significant symbols in the memory map) are empty.

## Status Interfaces

The FIFO provides two optional status interfaces, one for the master writing to the input interface and a second for the read master reading from the output interface. For FIFOs that operate in a single domain, a single status interface is sufficient to monitor the status of the FIFO. For FIFOs using a dual clocking scheme, a second status interface using the output clock is necessary to accurately monitor the status of the FIFO in both clock domains.

## Clocking Modes

When single clock mode is used, the FIFO being used is SCFIFO. When dual-clock mode is chosen, the FIFO being used is DCFIFO. In dual-clock mode, input data and write-side status interfaces use the write side clock domain; the output data and read-side status interfaces use the read-side clock domain.

## Device and Tools Support

The on-chip FIFO memory supports the Arria™ GX, Stratix® III, Stratix II GX, Stratix II, Stratix GX, Stratix, Cyclone® III, Cyclone II, Cyclone and Hardcopy® II device families.

## Instantiating the Core in SOPC Builder

Designers use the MegaWizard® interface for the on-chip FIFO memory in SOPC Builder to specify the core configuration. The following sections describe the available options in the MegaWizard interface.

### FIFO Settings

The following sections outline the settings that pertain to the FIFO as a whole.

#### *Depth*

**Depth** indicates the depth of the FIFO, in Avalon-ST beats or Avalon-MM words. The default depth is 16. When dual clock mode is used, the actual FIFO depth is equal to `depth-3`. This is due to clock crossing and to avoid FIFO overflow.

### *Clock Settings*

The two options are **Single clock mode** and **Dual clock mode**. In single clock mode, all interface ports use the same clock. In dual clock mode, input data and input side status are on the input clock domain. Output data and output side status are on the output clock domain.

### *Status Port*

The optional status ports are Avalon-MM slaves. To include the optional input side status interface, turn on **Create status interface for input** on the SOPC Builder MegaWizard. For FIFOs whose input and output ports operate in separate clock domains, you can include a second status interface by turning on **Create status interface for output**. Turning on **Enable IRQ for status ports** adds an interrupt signal to the status ports.

### *FIFO Implementation*

This option determines if the FIFO is built from registers or embedded memory blocks. The default is to construct the FIFO from embedded memory blocks.

## **Interface Parameters**

The following sections outline the options for the input and output interfaces.

### *Input*

Available input interfaces are **Avalon-MM** write slave and **Avalon-ST** sink.

### *Output*

Available output interfaces are **Avalon-MM** read slave and **Avalon-ST** source.

### *Allow Backpressure*

When **Allow backpressure** is on, an Avalon-MM interface will include the `waitrequest` signal which is asserted to prevent a master from writing to a full FIFO or reading from an empty FIFO. An Avalon-ST interface will include the `ready` and `valid` signals to prevent underflow and overflow conditions.

### *Avalon-MM Port Settings*

Valid **Data widths** are 8, 16, and 32 bits.

If Avalon-MM is selected for one interface and Avalon-ST for the other, the data width is fixed at 32 bits.

The Avalon-MM interface accesses data 4 bytes at a time. For data widths other than 32 bits, be cautious of potential overflow and underflow conditions.

### *Avalon-ST Port Settings*

The following parameters allow you to specify the size and error handling of the Avalon-ST port or ports:

- **Bits per symbol**
- **Symbols per beat**
- **Channel width**
- **Error width**

If the symbol size is not a power of two, it is rounded up to the next power of two. For example, if the bits per symbol is 10, the symbol will be mapped to a 16-bit memory location. With 10-bit symbols, the maximum number of symbols per beat is two.

**Enable packet data** provides an option for packet transmission.

## **Software Programming Model**

The following sections describe the software programming model for the on-chip FIFO memory core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the on-chip FIFO memory core using its HAL API.

### **HAL System Library Support**

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the on-chip FIFO memory via the familiar HAL API, rather than accessing the registers directly.

## Software Files

Altera provides the following software files for the on-chip FIFO memory core:

- **altera\_avalon\_fifo\_regs.h**—This file defines the core’s register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_fifo\_util.h**—This file defines functions to access the on-chip FIFO memory core hardware. It provides utilities to initialize the FIFO, read and write status, enable flags and read events.
- **altera\_avalon\_fifo.h**— This file provides the public interface to the on-chip FIFO memory
- **altera\_avalon\_fifo\_util.c**—This file implements the utilities listed in **altera\_avalon\_fifo\_util.h**.

## Programming with the On-Chip FIFO Memory

This section describes the low-level software constructs for manipulating the on-chip FIFO memory core hardware. [Table 5-3](#) lists all of the available functions.

**Table 5-3. On-Chip FIFO Memory Functions (Part 1 of 2)**

Function Name	Description
<code>altera_avalon_fifo_init()</code>	Initializes the FIFO.
<code>altera_avalon_fifo_read_status()</code>	Returns the integer value of the specified bit of the status register. To read all of the bits at once, use the <code>ALTERA_AVALON_FIFO_STATUS_ALL</code> mask.
<code>altera_avalon_fifo_read_ienable()</code>	Returns the value of the specified bit of the interrupt enable register. To read all of the bits at once, use the <code>ALTERA_AVALON_FIFO_EVENT_ALL</code> mask.
<code>altera_avalon_fifo_read_almostfull()</code>	Returns the value of the <code>almostfull</code> register.
<code>altera_avalon_fifo_read_almostempty()</code>	Returns the value of the <code>almostempty</code> register.
<code>altera_avalon_fifo_read_event()</code>	Returns the value of the specified bit of the event register. All of the event bits can be read at once by using the <code>ALTERA_AVALON_FIFO_STATUS_ALL</code> mask.
<code>altera_avalon_fifo_read_level()</code>	Returns the fill level of the FIFO.
<code>altera_avalon_fifo_clear_event()</code>	Clears the specified bits and the event register and performs error checking.
<code>altera_avalon_fifo_write_ienable()</code>	Writes the specified bits of the <code>interruptenable</code> register and performs error checking.

**Table 5–3. On-Chip FIFO Memory Functions (Part 2 of 2)**

Function Name	Description
<code>altera_avalon_fifo_write_almostfull()</code>	Writes the specified value to the <code>almostfull</code> register and performs error checking.
<code>altera_avalon_fifo_write_almostempty()</code>	Writes the specified value to the <code>almostempty</code> register and performs error checking.
<code>altera_avalon_fifo_write_fifo()</code>	Writes the specified data to the <code>write_address</code> .
<code>altera_avalon_fifo_write_other_info()</code>	Writes the packet status information to the <code>write_address</code> . Only valid when <b>Enable packet data</b> is on.
<code>altera_avalon_fifo_read_fifo()</code>	Reads data from the specified <code>read_address</code> .
<code>altera_avalon_fifo_read_other_info()</code>	Reads the packet status information from the specified <code>read_address</code> . Only valid when <b>Enable packet data</b> is on.

## Software Control

Table 5–4 provides the register map for the `status` register. The layout of `status` register for the input and output interfaces is identical.

**Table 5–4. FIFO Status Register Memory Map**

offset	31	24	23	16	15	8	7	6	5	4	3	2	1	0
base	fill_level													
base + 1											i_status			
base + 2											event			
base + 3											interruptenable			
base + 4	almostfull													
base + 5	almostempty													

Table 5–5 outlines the use of the various fields of the `status` register.

**Table 5–5. FIFO Status Field Descriptions (Part 1 of 2)**

Field	Type	Description
<code>fill_level</code>	RO	The instantaneous fill level of the FIFO, provided in units of symbols for a FIFO with an Avalon-ST FIFO and words for an Avalon-MM FIFO.
<code>i_status</code>	RO	A 6-bit register that shows the FIFO's instantaneous status. See Table 5–6 for the meaning of each bit field.

**Table 5–5. FIFO Status Field Descriptions (Part 2 of 2)**

Field	Type	Description
event	RW1C	A 6-bit register with exactly the same fields as <code>i_status</code> . When a bit in the <code>i_status</code> register is set, the same bit in the <code>event</code> register is set. The bit in the <code>event</code> register is only cleared when software writes a 1 to that bit.
interruptenable	RW	A 6-bit interrupt enable register with exactly the same fields as the <code>event</code> and <code>i_status</code> registers. When a bit in the <code>event</code> register transitions from a 0 to a 1, and the corresponding bit in <code>interruptenable</code> is set, the master is interrupted.
almostfull	RW	A threshold level used for interrupts and status. Can be written by the Avalon-MM status master at any time. The default threshold value for DCFIFO is Depth-4. The default threshold value for SCFIFO is Depth-1. The valid range of the threshold value is from 1 to the default. 1 will be used when attempting to write a value smaller than 1. The default will be used when attempting to write a value larger than the default.
almostempty	RW	A threshold level used for interrupts and status. Can be written by the Avalon-MM status master at any time. The default threshold value for DCFIFO is 1. The default threshold value for SCFIFO is 1. The valid range of the threshold value is from 1 to the maximum allowable almostfull threshold. 1 will be used when attempting to write a value smaller than 1. The maximum allowable will be used when attempting to write a value larger than the maximum allowable.

Table 5–6 describes the instantaneous status bits.

**Table 5–6. Status Bit Field Descriptions**

Bit(s)	Name	Description
1	FULL	Has a value of 1 if the FIFO is currently full.
0	EMPTY	Has a value of 1 if the FIFO is currently empty.
3	ALMOSTFULL	Has a value of 1 if the fill level of the FIFO is greater than the <code>almostfull</code> value.
2	ALMOSTEMPTY	Has a value of 1 if the fill level of the FIFO is less than the <code>almostempty</code> value.
4	OVERFLOW	Is set to 1 for 1 cycle every time the FIFO overflows. The FIFO overflows when an Avalon write master writes to a full FIFO. OVERFLOW is only valid when <b>Allow backpressure</b> is off.
5	UNDERFLOW	Is set to 1 for 1 cycle every time the FIFO underflows. The FIFO underflows when an Avalon read master reads from an empty FIFO. UNDERFLOW is only valid when <b>Allow backpressure</b> is off.

Table 5-7 lists the bit fields of the event register. These fields are identical to those in the status register and are set at the same time; however, these fields are only cleared when software writes a one to clear (W1C). The event fields can be used to determine if a particular event has occurred.

Bit(s)	Name	Description
1	E_FULL	Has a value of 1 if the FIFO has been full and the bit has not been cleared by software.
0	E_EMPTY	Has a value of 1 if the FIFO has been empty and the bit has not been cleared by software.
3	E_ALMOSTFULL	Has a value of 1 if the fill level of the FIFO has been greater than the <code>almostfull</code> threshold value and the bit has not been cleared by software.
2	E_ALMOSTEMPTY	Has a value of 1 if the fill level of the FIFO has been less than the <code>almostempty</code> value and the bit has not been cleared by software.
4	E_OVERFLOW	Has a value of 1 if the FIFO has overflowed and the bit has not been cleared by software.
5	E_UNDERFLOW	Has a value of 1 if the FIFO has underflowed and the bit has not been cleared by software.

Table 5-8 provides a mask for the six STATUS fields. When a bit in the event register transitions from a zero to a one, and the corresponding bit in the interruptenable register is set, the master is interrupted.

Bit(s)	Name	Description
1	IE_FULL	Enables an interrupt if the FIFO is currently full.
0	IE_EMPTY	Enables an interrupt if the FIFO is currently empty.
3	IE_ALMOSTFULL	Enables an interrupt if the fill level of the FIFO is greater than the value of the <code>almostfull</code> register.
2	IE_ALMOSTEMPTY	Enables an interrupt if the fill level of the FIFO is less than the value of the <code>almostempty</code> register.
4	IE_OVERFLOW	Enables an interrupt if the FIFO overflows. The FIFO overflows when an Avalon write master writes to a full FIFO.

<b>Table 5–8. InterruptEnable Bit Field Descriptions (Part 2 of 2)</b>		
<b>Bit(s)</b>	<b>Name</b>	<b>Description</b>
5	IE_UNDERFLOW	Enables an interrupt is the FIFO underflows. The FIFO underflows when an Avalon read master reads from an empty FIFO.
6	ALL	Enables all 6 status conditions to interrupt.

Macros to access all of the registers are defined in **altera\_avalon\_fifo\_regs.h**. For example, this file includes the following macros to access the status register.

```
#define ALTERA_AVALON_FIFO_LEVEL_REG      0
#define ALTERA_AVALON_FIFO_STATUS_REG    1
#define ALTERA_AVALON_FIFO_EVENT_REG     2
#define ALTERA_AVALON_FIFO_IENABLE_REG   3
#define ALTERA_AVALON_FIFO_ALMOSTFULL_REG 4
#define ALTERA_AVALON_FIFO_ALMOSTEMPTY_REG 5
```

For a complete list of predefined macros and utilities to access the on-chip FIFO hardware, see:

```
<install_dir>\quartus\sopc_builder\components\altera_avalon_fifo
\HAL\inc\alatera_avalon_fifo.h and
<install_dir>\quartus\sopc_builder\components\altera_avalon_fifo
\HAL\inc\alatera_avalon_fifo_util.h.
```

## Software Example

An extensive programming example for the on-chip FIFO memory appears next to this document on the Quartus II literature page. Visit [www.altera.com/literature/quartus2/lit-qts-peripherals.jsp](http://www.altera.com/literature/quartus2/lit-qts-peripherals.jsp).

**Example 5–1. Sample Code for the On-Chip FIFO Memory**

```

/*****
//Includes
#include "altera_avalon_fifo_regs.h"
#include "altera_avalon_fifo_util.h"
#include "system.h"
#include "sys/alt_irq.h"
#include <stdio.h>
#include <stdlib.h>

#define ALMOST_EMPTY 2
#define ALMOST_FULL OUTPUT_FIFO_OUT_FIFO_DEPTH-5

---

## On-Chip FIFO Memory API

This section describes the application programming interface (API) for the on-chip FIFO memory core.

## altera\_avalon\_fifo\_init()

**Prototype:** `int altera_avalon_fifo_init(alt_u32 address, alt_u32 ienable, alt_u32 emptymark, alt_u32 fullmark)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:**  
`address`—the base address of the FIFO control slave  
`ienable`—the value to write to the interruptenable register  
`emptymark`—the value for the almost empty threshold level  
`fullmark`—the value for the almost full threshold level

**Returns:** Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_EVENT_CLEAR_ERROR` for clear errors, `ALTERA_AVALON_FIFO_IENABLE_WRITE_ERROR` for interrupt enable write errors, `ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` for errors writing the `almostfull` and `almostempty` registers.

**Description:** Clears the event register, writes the interruptenable register, and sets the `almostfull` register and `almostempty` registers.

---

## altera\_avalon\_fifo\_read\_status()

**Prototype:** `int altera_avalon_fifo_read_status(alt_u32 address, alt_u32 mask)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`mask`—masks the read value from the status register

**Returns:** Returns the fill level of the FIFO.

**Description:** Gets the fill level of the FIFO which is the AND of the value of the addressed register and the mask.

## altera\_avalon\_fifo\_read\_ienable()

**Prototype:** `int altera_avalon_fifo_read_ienable(alt_u32 address, alt_u32 mask)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`mask`—masks the read value from the `interruptenable` register

**Returns:** Returns the logical AND of the `interruptenable` register and the mask.

**Description:** Gets the logical AND of the `interruptenable` register and the mask.

---

## altera\_avalon\_fifo\_read\_almostfull()

**Prototype:** `int altera_avalon_fifo_read_almostfull(alt_u32 address)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave

**Returns:** Returns the value of the `almostfull` register.

**Description:** Gets the value of the `almostfull` register.

## altera\_avalon\_fifo\_read\_almostempty()

**Prototype:** `int altera_avalon_fifo_read_almostempty(alt_u32 address)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave

**Returns:** Returns the value of the `almostempty` register.

**Description:** Gets the value of the `almostempty` register.

---

## altera\_avalon\_fifo\_read\_event()

**Prototype:** `int altera_avalon_fifo_read_event(alt_u32 address, alt_u32 mask)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`mask`—masks the read value from the event register

**Returns:** Returns the logical AND of the `event` register and the mask.

**Description:** Gets the logical AND of the `event` register and the mask. To read single bits of the event register use the single bit masks, for example: `ALTERA_AVALON_FIFO_FIFO_EVENT_F_MSK`. To read the entire event register use the full mask: `ALTERA_AVALON_FIFO_EVENT_ALL`.

## altera\_avalon\_fifo\_read\_level()

**Prototype:** `int altera_avalon_fifo_read_level(alt_u32 address)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave

**Returns:** Returns the fill level of the FIFO.

**Description:** Gets the fill level of the FIFO.

---

## altera\_avalon\_fifo\_clear\_event()

**Prototype:** `int altera_avalon_fifo_clear_event(alt_u32 address, alt_u32 mask)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`mask`—the mask to use for bit-clearing (1 means clear this bit, 0 means don't)

**Returns:** Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful,  
`ALTERA_AVALON_FIFO_EVENT_CLEAR_ERROR` if unsuccessful.

**Description:** Clears the specified bits of the `event` register.

## altera\_avalon\_fifo\_write\_ienable()

- Prototype:**            `int altera_avalon_fifo_write_ienable(alt_u32 address, alt_u32 mask)`
- Thread-safe:**        No.
- Available from ISR:** No.
- Include:**            `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`
- Parameters:**        `address`—the base address of the FIFO control slave  
`mask`—the value to write to the `interruptenable` register. See `altera_avalon_fifo_regs.h` for individual interrupt bit masks.
- Returns:**            Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful,  
`ALTERA_AVALON_FIFO_IENABLE_WRITE_ERROR` if unsuccessful.
- Description:**        Writes the specified bits of the `interruptenable` register.

---

## altera\_avalon\_fifo\_write\_almostfull()

**Prototype:** `int altera_avalon_fifo_write_almostfull(alt_u32 address,  
alt_u32 data)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`data`—the value for the almost full threshold level

**Returns:** Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful,  
`ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` if unsuccessful.

**Description:** Writes `data` to the `almostfull` register.

## altera\_avalon\_fifo\_write\_almostempty()

**Prototype:** `int altera_avalon_fifo_write_almostempty(alt_u32 address,  
alt_u23 data)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `address`—the base address of the FIFO control slave  
`data`—the value for the almost empty threshold level

**Returns:** Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful,  
`ALTERA_AVALON_FIFO_THRESHOLD_WRITE_ERROR` if unsuccessful.

**Description:** Writes data to the `almostempty` register.

## altera\_avalon\_write\_fifo()

- Prototype:** `int altera_avalon_write_fifo(alt_u32 write_address, alt_u32 ctrl_address, alt_u32 data)`
- Thread-safe:** No.
- Available from ISR:** No.
- Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`
- Parameters:** `write_address`—the base address of the FIFO write slave  
`ctrl_address`—the base address of the FIFO control slave  
`data`—the value to write to address offset 0 for Avalon-MM to Avalon-ST transfers, the value to write to the single address available for Avalon-MM to Avalon-MM transfers. See the *Avalon Memory-Mapped and Avalon Streaming Interface Specifications* for the data ordering.
- Returns:** Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful, `ALTERA_AVALON_FIFO_FULL` if unsuccessful.
- Description:** Writes `data` to the specified address if the FIFO is not full.

## altera\_avalon\_write\_other\_info()

**Prototype:**            `int altera_avalon_write_other_info(alt_u32 write_address,  
alt_u32 ctrl_address, alt_u32 data)`

**Thread-safe:**        No.

**Available from ISR:** No.

**Include:**            `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:**        `write_address`—the base address of the FIFO write slave  
`ctrl_address`—the base address of the FIFO control slave  
`data`—the packet status information to write to address offset 1 of the Avalon interface. See the *Avalon Memory-Mapped and Avalon Streaming Interface Specifications* for the ordering of the packet status information.

**Returns:**            Returns 0 (`ALTERA_AVALON_FIFO_OK`) if successful,  
`ALTERA_AVALON_FIFO_FULL` if unsuccessful.

**Description:**        Writes the packet status information to the `write_address`. Only valid when **Enable packet data** is on.

---

## altera\_avalon\_fifo\_read\_fifo()

**Prototype:** `int altera_avalon_fifo_read_fifo(alt_u32 read_address,  
alt_u32 ctrl_address)`

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`

**Parameters:** `read_address`—the base address of the FIFO read slave  
`ctrl_address`—the base address of the FIFO control slave

**Returns:** Returns the data from address offset 0, or 0 if the FIFO is empty.

**Description:** Gets the data addressed by `read_address`.

## altera\_avalon\_fifo\_read\_other\_info()

- Prototype:** `int altera_avalon_fifo_read_other_info(alt_u32 read_address)`
- Thread-safe:** No.
- Available from ISR:** No.
- Include:** `<altera_avalon_fifo_regs.h>`, `<altera_avalon_fifo_utils.h>`
- Parameters:** `read_address`—the base address of the FIFO read slave
- Returns:** Returns the packet status information from address offset 1 of the Avalon interface. See the *Avalon Memory-Mapped and Avalon Streaming Interface Specifications* for the ordering of the packet status information.
- Description:** Reads the packet status information from the specified `read_address`. Only valid when **Enable packet data** is on.

May 2007 v7.1.0	Initial release.	—

### Core Overview

The Scatter-Gather direct memory access (SG-DMA) controller core implements high-speed data transfer between two devices. The SG-DMA core can be used to transfer data from the following sources:

- Memory to memory
- Data stream to memory
- Memory to data stream

The SG-DMA controller core transfers and merges non-contiguous memory to a continuous address space. It also transfers contiguous memory to non-contiguous memory. The core operates by reading a series of descriptors that specify the data to be transferred.

For applications requiring more than one DMA channel, multiple instantiations of the core can provide the required throughput. Each SG-DMA controller has its own series of descriptors specifying the data transfers. A single software module controls all of the DMA channels.

The SG-DMA controller core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. For the Nios® II processor, device drivers are provided in the HAL system library, allowing software to access the core using the ANSI C Standard Library `stdio.h` routines.

### Example Systems

Figure 6-1 shows a SG-DMA controller core in a block diagram for the DMA subsystem of a printed circuit board. The SG-DMA core in the FPGA reads streaming data from an internal streaming component and writes data to an external memory. A Nios II processor provides overall system control. The descriptor table, containing the linked list of descriptors specifying data transfers to be executed, can be located in the FPGA or an external memory. Locating this table in an external memory will free up resources in the FPGA; however, an external descriptor table will increase the overhead involved when the descriptor processor reads and updates the table. The SG-DMA core has an internal FIFO to store descriptors read from memory, which allows it to perform descriptor read, execute, and write back operations in parallel, hiding the descriptor read latency.

**Figure 6–1. Scatter-Gather DMA Controller Core with Streaming Peripheral and External Memory**

- M** Avalon-MM Master Port
- S** Avalon-MM Slave Port
- ST** Avalon-ST Sink Port

Figure 6–2 shows a different use of the SG-DMA controller core. In Figure 6–2, SG-DMA core transfers data between an internal and external memory. The host processor and memory are on the system bus, typically either a PCI-Express or Serial RapidIO™.

**Figure 6–2. Scatter-Gather DMA Controller Core with Internal and External Memory**

Figures 6–1 and 6–2 illustrate systems using the SG-DMA controller core and omit some of the internals of the core itself. Figure 6–3 on page 6–7 illustrates all of the SG-DMA controller core internals.

## Resource Usage and Performance

Resource utilization for the core is 600–1400 LEs, depending upon the width of the datapath, the parameterization of the core, and the type of data transfer. Table 6–1 provides resource utilization for a SG-DMA

controller core used for memory to memory transfer. The core is highly parameterized and the resource utilization will vary with the configuration specified.

**Table 6–1. SG-DMA Estimated Resource Usage**

Datapath	Cyclone® II	Stratix® (Approx. LEs)	Stratix II (Approx. ALUTs)
8-bit datapath	850	650	600
32-bit datapath	1100	850	700
64-bit datapath	1250	1250	800

The core operating frequency varies with the device and the size of the datapath. Table 6–2 provides an example of expected performance for SG-DMA cores instantiated in several different device families.

**Table 6–2. SG-DMA Performance Estimates**

Device	Datapath	f <sub>MAX</sub>	Throughput
Cyclone II	64 bits	150 MHz	9.6 Gbps
Cyclone III	64 bits	160 MHz	10.2 Gbps
Stratix II/Stratix II GX	64 bits	250 MHz	16.0 Gbps
Stratix III	64 bits	300 MHz	19.2 Gbps

## Comparison of SG-DMA Controller Core and DMA Controller Core

The SG-DMA controller core provides a significant performance enhancement over the previously available DMA controller core, which could only perform a single DMA transfer at a time. With the older DMA controller core, a CPU performed separate reads for each entry of the DMA descriptor table and then executed separate IO writes to program the DMA controller to perform the transfer. Transfers to non-contiguous memory could not be linked; consequently, the CPU overhead was substantial for small transfers, degrading overall system performance. In contrast, the SG-DMA controller core reads a series of descriptors from memory that describe the required transactions and performs all of the transfers without additional intervention from the CPU.

## Functional Description

The SG-DMA controller core comprises three major blocks: a descriptor processor, a DMA read block and a DMA write block. (See [Figure 6-3 on page 6-7](#).) These blocks are combined to create three different configurations:

- memory to memory
- memory to stream
- stream to memory

For the memory-to-memory configuration, the core includes all three blocks. If the core is configured for memory-to-stream transactions, only the descriptor processor and read blocks are required. If the core is configured for stream-to-memory transactions, only the descriptor processor and write blocks are required. In the memory-to-memory configuration, an internal FIFO holds data being transferred between the read and write blocks. In the other two configurations, an external FIFO might be required depending upon the throughput of the components being connected. For designs requiring an external FIFO, the on-chip FIFO memory available in SOPC Builder can be used.

The following sections describe the three configurations of the SG-DMA controller core and the behavior of the internal modules for each configuration.

### Memory-to-Memory Configuration

As [Figure 6-3](#) illustrates, the memory-to-memory configuration includes five Avalon-MM ports. The descriptor processor block uses read and write Avalon-MM master ports to access and update descriptors. The DMA read block has an Avalon-MM master read port to read data from memory; it has an Avalon-ST port to pass data to the DMA write block. The DMA write block has an Avalon-ST port to receive data from the read block and an Avalon-MM master write port to write the data to memory. Software accesses an Avalon-MM slave port to read and write the control and status registers.

In the memory-to-memory configuration, the descriptor processor reads descriptors from the descriptor table and pushes the appropriate commands onto the input FIFOs of the DMA read and write blocks. It also receives a status token from the read or write block after each descriptor has been processed. The status token contains information about the status of the transfer, including the number of bytes transferred. The descriptor processor then writes this information back to the appropriate entry in the descriptor table.

In the memory-to-memory configuration, an internal data FIFO stores data being transferred between the read and write blocks to provide buffering and flow control.

To execute a DMA read transfer between memories, the following steps are executed:

1. Software writes the descriptor into memory.
2. Software writes the location of the first descriptor address to SG-DMA controller hardware and initiates the transfer by setting the RUN bit of the SG-DMA control register.
3. The descriptor processor reads the descriptors from memory and writes them into a command FIFO which feeds commands to both the DMA read and write blocks.
4. The DMA write block gets the destination address from its command FIFO. The write block continues to execute writes until the specified number of bytes have been transferred. It then sends a status update to the DMA controller. If the data FIFO ever empties, the write block pauses until the FIFO has more data to write.
5. The descriptor processor updates the appropriate entry in the descriptor table.

Figure 6–3 illustrates one possible configuration for the memory-to-memory SG-DMA controller with an internal Nios II processor and descriptor table.

Figure 6–3. Scatter-Gather DMA Controller Core for Memory-to-Memory Configuration

-  Avalon-MM Master Port
-  Avalon-MM Slave Port
-  Avalon-ST Source Port
-  Avalon-ST Sink Port

### Memory-to-Stream Configuration

The memory-to-stream configuration includes the descriptor processor and the DMA read block. As Figure 6–3 illustrates, this configuration includes four Avalon-MM ports and one Avalon-ST port. The descriptor processor block includes read and write Avalon-MM master ports to

access and update descriptors. The DMA read block has an Avalon-MM master read port to read data from memory and an Avalon-ST port to write the data to a streaming component. An Avalon-MM slave port is used to read and write the control and status registers.

Figure 6–4 on page 6–9 illustrates a SG-DMA controller in the memory-to-stream configuration. In this example, the Nios II processor and descriptor table are inside the FPGA. Data from an external DDR2 memory is read by the SG-DMA controller and written to an internal streaming peripheral. The read block returns status to the descriptor processor upon completion of each descriptor.

Figure 6–4. Scatter-Gather DMA Controller Memory-to-Stream Configuration

The transfer operation includes the following steps:

1. Software writes the descriptor into memory.
2. Software writes the location of first descriptor address to SG-DMA controller hardware and initiates the transfer by setting the RUN bit of the SG-DMA control register.

3. The descriptor processor reads the descriptors from memory and writes them into the input command FIFO in the read block.
4. The read block reads from the source address and pushes the data to its stream port. The read block continues reads until the specified number of bytes have been transferred. It then sends a status update to the descriptor processor.
5. The descriptor processor updates the appropriate entry in the descriptor table.

### Stream-to-Memory Configuration

The stream-to-memory configuration includes the descriptor processor and the DMA write block. The write block returns status to the descriptor processor upon completion of each descriptor. This configuration is similar to the memory-to-stream configuration except that the data flows from a streaming component to a memory device as [Figure 6–5](#) illustrates. In this example, an On-Chip FIFO Memory component is used to provide a buffer between the streaming component and the DMA write.

The transfer operation includes the following steps:

1. Software writes the descriptor into memory.
2. Software writes the location of the first descriptor address to SG-DMA controller hardware and initiates the transfer by writing the RUN bit of the SG-DMA `control` register.
3. The descriptor processor reads the descriptors from memory and writes them into the write block.
4. The write block reads from its stream port and writes the data to its Avalon master port. The write block continues reads until the specified number of bytes have been transferred. It then sends a status update to the descriptor processor.
5. The descriptor processor updates the appropriate entry in the descriptor table.

Figure 6–5. Scatter-Gather DMA Controller Stream-to-Memory Configuration

## Possible Sources of Errors

The SG-DMA core has a parameterizable error width. Error signals are wired directly to the Avalon-ST source or sink to which the SG-DMA core is connected. [Table 6–3](#) lists the error signals when the core is operating in the memory to stream configuration and connected to the transmit FIFO interface of the Altera Triple-Speed Ethernet MegaCore®.

**Table 6–3. Avalon-ST Transmit Channel Error Types**

Signal Type	Description
TSE_transmit_error[0]	Transmit Frame Error. Asserted to indicate that the transmitted frame should be viewed as invalid by the Ethernet MAC. The frame is then transferred onto the GMII interface with an error code during the frame transfer.

[Table 6–4](#) lists the error signals when the core is operating in the stream-to-memory configuration and connected to the transmit FIFO interface of the Altera Triple-Speed Ethernet MegaCore.

**Table 6–4. Avalon-ST Receive Channel Error Types**

Signal Type	Description
TSE_receive_error[0]	Receive Frame Error. This signal indicates that an error has occurred. It is the logical OR of receive errors 1 through 5.
TSE_receive_error[1]	Invalid Length Error. Asserted when the received frame has an invalid length as defined by the IEEE 802.3 standard.
TSE_receive_error[2]	CRC Error. Asserted when the frame has been received with a CRC-32 error.
TSE_receive_error[3]	Receive Frame Truncated. Asserted when the received frame has been truncated due to receive FIFO overflow.
TSE_receive_error[4]	Received Frame corrupted due to PHY error. (The PHY has asserted an error on the receive GMII interface.)
TSE_receive_error[5]	Collision Error. Asserted when the frame was received with a collision.

## Detailed Description of Each Block

The following sections provide a detailed description of each functional block.

### Descriptor Processor Block

The descriptor processor reads descriptors from memory using its Avalon-MM descriptor read master port and pushes commands onto the command FIFOs of the DMA read and write blocks. The command includes the following fields to specify the transfers:

- source address
- destination address
- read size
- write size
- bytes to transfer
- increment read address after each transfer
- increment write address after each transfer
- generate end of packet

### DMA Read Block

The DMA read block reads commands from its input command FIFO. For each command, it reads data from the source address on its Avalon-MM port. In the memory-to-memory configuration, it pushes the data into the data FIFO. In the memory-to-stream configuration, it immediately writes the data to the Avalon-ST source port.

The DMA read block will not begin an Avalon-MM read unless its data FIFO has enough space to store all of the data read. This restriction requires the external FIFO be at least as deep as the maximum supported read size.

### DMA Write Block

The DMA write block reads commands from its input command FIFO. For each command, it writes data received on its Avalon-ST sink port to the destination address. In the memory-to-memory and the stream-to-memory configurations, it reads the data from its Avalon-ST port and writes to its Avalon-MM port.

## Device Support and Tools

The SG-DMA controller core supports the Arria™ GX, Stratix III, Stratix II GX, Stratix II, Stratix, Cyclone III, Cyclone II, Cyclone and Hardcopy® II device families.

## Instantiating the Core in SOPC Builder

Hardware designers use the MegaWizard interface for the SG-DMA controller core in SOPC Builder to specify the core configuration.

If an SOPC Builder system contains both the SG-DMA controller and JTAG UART cores, set the IRQs for the SG-DMA controller core to a higher priority than the IRQs for the JTAG UART core.

The following sections describe the available options in the configuration wizard.

### Transfer Mode

This list allows you to select between the **Memory To Memory**, **Memory To Stream**, and **Stream To Memory** configurations. For more information about these configurations, see [“Memory-to-Memory Configuration” on page 6–5](#), [“Memory-to-Stream Configuration” on page 6–7](#), and [“Stream-to-Memory Configuration” on page 6–10](#).

### Allow Unaligned Transfers

If **Allow unaligned transfers** is on, data transfers for data widths that are not a power of two will be aligned on word boundaries. Unaligned transfers require extra logic that may negatively impact system performance.

### Data and Error Widths

The **Data width** list allows you to select data width in bits for the Avalon-MM read and write ports. The **Source error width** and **Sink error width** lists allow you to select widths of the error signals for the Avalon-ST source and sink ports.

### FIFO Depth

The **Data transfer FIFO depth** list sets the depth for all three descriptor FIFOs:

- the Descriptor Processor block FIFO
- the DMA read block FIFO
- the DMA write block FIFO

The **Data transfer FIFO depth** list also sets the depth for the internal data FIFO used in the memory-to-memory configuration. These FIFOs are all illustrated in [Figure 6–3 on page 6–7](#).

## Hardware Simulation Considerations

Signals for hardware simulation are automatically generated and show up as part of the Nios II simulation accessible from the Nios II IDE. On the Run menu, point to Run As and click **Nios II Modelsim**.

## Software Programming Model

The following sections describe the software programming model for the SG-DMA controller core.

### HAL System Library Support

The Altera-provided driver implements a HAL device driver that integrates into the HAL system library for Nios II systems. HAL users should access the SG-DMA controller core via the familiar HAL API and the ANSI C standard library.

### Software Files

The SG-DMA controller provides the following software files. These files provide low-level access to the hardware and drivers that integrate into the Nios II HAL system library. Application developers should not modify these files.

- **altera\_avalon\_sgdma\_regs.h**—defines the core's register map, providing symbolic constants to access the low-level hardware
- **altera\_avalon\_sgdma.h**—provides definitions for the Altera Avalon SG-DMA buffer control and status flags.
- **altera\_avalon\_sgdma.c**—provides function definitions for the code that implements the SG-DMA controller core.
- **altera\_avalon\_sgdma\_descriptor.h**—defines the core's descriptor, providing symbolic constants to access the low-level hardware.

## Programming with the SG-DMA Controller

This section describes the software constructs for programming the SG-DMA Controller.

**Table 6–5. SG-DMA Controller Functions**

Function Name	Description
<code>alt_avalon_sgdma_do_async_transfer()</code>	Sets up and begins a non-blocking transfer of one or more descriptors or a descriptor chain.
<code>alt_avalon_sgdma_do_sync_transfer()</code>	Sends a fully formed descriptor, or list of descriptors, to the SG-DMA Controller for transfer. This function will block both before transfer if the controller is busy and until the requested transfer has completed.
<code>alt_avalon_sgdma_construct_mem_to_mem_desc()</code>	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-MM to Avalon-MM transfer.
<code>alt_avalon_sgdma_construct_stream_to_mem_desc()</code>	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-ST to Avalon-MM transfer.
<code>alt_avalon_sgdma_construct_mem_to_stream_desc()</code>	Constructs a single SG-DMA descriptor in the specified memory for an Avalon-MM to Avalon-ST transfer.
<code>alt_avalon_sgdma_check_descriptor_status()</code>	Reads the <code>status</code> register of the descriptor.
<code>alt_avalon_sgdma_register_callback()</code>	Associates a user-specific routine with the SG-DMA interrupt handler.
<code>alt_avalon_sgdma_start()</code>	Starts the DMA engine.
<code>alt_avalon_sgdma_stop()</code>	Stops the DMA engine.
<code>alt_avalon_sgdma_open()</code>	Retrieves a pointer to the SG-DMA controller with the given name.

### Software Control

The host processor programs the SG-DMA by writing to its `control` register. The host processor reads SG-DMA `status` register to determine the current status.

Table 6–6 shows the offsets for the control and status registers.

Offset	Register Name
base + 0	status
base + 1	control
base + 2	next_descriptor_pointer

Software writes the control register to specify the behavior of the SG-DMA controller. This register determines the conditions under which the SG-DMA controller will generate an interrupt. It also includes the control bits used to start and stop processing descriptors.

 Bursting to the control port is not supported.

Table 6–7 provides a bit-map for the control register.

Bit	Bit Name	Rd/Wr/Clr	Description
0	IE_ERROR	R/W	Assert an interrupt when (ERROR = 1).
1	IE_EOP_ENCOUNTERED	R/W	Assert an interrupt when (EOP_ENCOUNTERED = 1).
2	IE_DESCRIPTOR_COMPLETED	R/W	Assert an interrupt when (DESCRIPTOR_COMPLETED = 1).
3	IE_CHAIN_COMPLETED	R/W	Assert an interrupt when (CHAIN_COMPLETED = 1).
4	IE_GLOBAL	R/W	Global signal to enable all interrupts.
5	RUN	R/W	The SG-DMA processes descriptors in its queue as long as RUN = 1. The SG-DMA will not process the next descriptor in its queue when RUN = 0. Setting RUN starts the descriptor processor that initiates DMA transactions. Clearing RUN will not stop processing of a descriptor if processing has already begun.
6	STOP_DMA_ER	R/W	Stops DMA after current descriptor if ERROR is detected.
7	IE_MAX_DESC_PROCESSED (1)	R/W	Enables interrupts when MAX_DESC_PROCESSED is reached.
8..15	MAX_DESC_PROCESSED (1)	R/W	Specifies the number of descriptors to process before invoking interrupt.

**Table 6–7. SG-DMA Control Register Map (Part 2 of 2)**

Bit	Bit Name	Rd/Wr/Clr	Description
16	SW_RESET	R/W	Resets the SG-DMA hardware and stops all operations immediately.
17	PARK	R/W	Enables the hardware to repeatedly use the same descriptor without software intervention. The bit <code>owned_by_hw</code> is not cleared, thus allowing the hardware to reuse the descriptor.
18..30	Reserved		
31	CLEAR_INTERRUPT	R/W	Set this bit to 1 to clear pending interrupts.

Note to **Table 6–7**:

- (1) Available if interrupt coalescing is selected in the synthesis options.

**Table 6–8** provides a bit-map for the status register.

**Table 6–8. SG-DMA Status Register Map**

Bit	Bit Name	Rd/Wr/Clr	Description
0	ERROR	R/C (1)(2)	Avalon-ST error encountered during transfer.
1	EOP_ENCOUNTERED	R/C	Transfer terminated by Avalon-ST EOP .
2	DESCRIPTOR_COMPLETED	R/C (1)(2)	A descriptor was processed to completion.
3	CHAIN_COMPLETED	R/C (1)(2)	Unable to process next descriptor because Owned by HW = 0.
4	BUSY	R/C (1)(3)	Indicates that descriptors are being processed; the linked list of descriptors is not yet completed.
5 .. 31	reserved		

Notes to **Table 6–8**:

- (1) This bit must be cleared after a read is performed. Write one to clear this bit.  
 (2) This bit is updated by hardware after each DMA transfer completes. It remains set until software writes one to clear.  
 (3) This bit is continuously updated by the hardware.

### Next Descriptor Pointer

Software writes the address of the first descriptor to this register as part of the system initialization sequence. When `RUN = 1`, the SG-DMA updates this register with the location of the next descriptor to be fetched. To stop execution of the SG-DMA core, software clears the `RUN` bit. When `RUN` is 0, the SG-DMA hardware completes the data transfers for the current descriptor and then stops processing. Software can then modify the remaining linked-list and restart the SG-DMA hardware.

While  $BUSY = 1$ , the next descriptor pointer is updated by hardware. The next descriptor pointer can only be reliably read by software when  $BUSY = 0$ .

## DMA Descriptors

The DMA descriptors specify all information required to perform data transfers, including: the source address, destination address, and the number of bytes to be transferred. The descriptors are stored in a table that is written by software. This table can be stored in FPGA memory or an external memory device as a linked list. The descriptor must be initialized by user applications and aligned on a 256-bit boundary.

Table 6–9 shows the layout of a descriptor entry.

Offset	Bit Field Names						
	31	24	23	16	15	8	7
base	SOURCE						
base + 1	RESERVED						
base + 2	DESTINATION						
base + 3	RESERVED						
base + 4	NEXT_DESC_PTR						
base + 5	RESERVED						
base + 6	WRITE_		READ_		BYTES_TO_TRANSFER		
base + 7	DESC_CONTROL		DESC_STATUS		ACTUAL_BYTES_TRANSFERRED		

Table 6–10 describes the function of the various fields.

Field Name	Rd/Wr/Clr	Description
SOURCE	R/W	Specifies the address of data to be read. This address is set to 0 if the input source is an Avalon Streaming (Avalon-ST) interface.
DESTINATION	R/W	Specifies the address to which data should be written. This address is set to 0 if the write data is an Avalon-ST interface.
NEXT_DESC_PTR	R/W	Specifies the next descriptor in the linked list.

<b>Table 6–10. Descriptor Field Descriptions (Part 2 of 2)</b>		
<b>Field Name</b>	<b>Rd/Wr/Clr</b>	<b>Description</b>
BYTES_TO_TRANSFER	R/W	Specifies the number of bytes to transfer. If BYTES_TO_TRANSFER = 0, the transaction will be terminated by an EOP.
READ_	R/W	
WRITE_	R/W	
ACTUAL_BYTES_TRANSFERRED	R	Specifies the number of bytes that are successfully transferred by the DMA hardware.
DESC_CONTROL	R/W	See Table 6–12 for descriptions of each bit.
DESC_STATUS	R/W	See Table 6–11 for descriptions of each bit.

The descriptor processor reads the DESC\_CONTROL fields to determine how to proceed with the DMA transaction. Table 6–11 provides a bit-map for these fields.

<b>Table 6–11. Desc_Control Field Map</b>			
<b>Bits</b>	<b>Field Name</b>	<b>Rd/Wr/Clr</b>	<b>Description</b>
0	Generate_EOP	W	When set, DMA Read should generate an EOP on the final word.
1	Read_Fixed_Address	R/W	For Avalon-MM ports, when set to 1, DMA Read does not increment the memory address. When 0, the read address increments after each read.  When used in Memory-to-Stream mode, the read engine generates a startofpacket signal on the first word.
2	Write_Fixed_Address	R/W	Used only for Avalon-MM ports. When set to 1, DMA Write does not increment the memory address. When 0, the write address increments after each write.
3 .. 6	Avalon-ST_Channel_Number	R/W	DMA Read drives this value onto the Avalon-ST channel port for each word in the transaction. The DMA Write replaces this value with the Avalon-ST channel number for its sink port.
7	Owned_by_HW	R/W	This bit determines whether hardware or software has write access to the descriptor of the SG-DMA control and status register. When Owned_by_HW=1 the hardware can update this pointer. When Owned_by_HW=0, software can update this pointer.

After completing a DMA transaction, the descriptor processor updates the `DESC_STATUS` fields to indicate how the transaction proceeded. The error conditions these fields record can only occur on an Avalon-ST interface. Table 6–12 provides a bit-map for the `DESC_STATUS` fields.

**Table 6–12. Descriptor Desc\_Status Bit Map**

Bit	Bit Name	Rd/Wr/Clr	Description
0	E_CRC	R	When set, indicates that a CRC error occurred on the Avalon-ST interface.
1	E_PARITY	R	When set, indicates that a parity error occurred on the Avalon-ST interface.
2	E_OVERFLOW	R	When set, indicates that an overflow occurred on the Avalon-ST interface.
3	E_SYNC	R	When set, indicates that an out-of-sync error occurred on the Avalon-ST interface.
4	E_UEOP	R	When set, indicates that an unexpected EOP error occurred on the Avalon-ST interface.
5	E_MEOP	R	When set, indicates that a missing EOP error occurred on the Avalon-ST interface.
6	E_MSOP	R	When set, indicates that a missing SOP error occurred on the Avalon-ST interface.
7	Terminated_by_EOP	R	When set, indicates that a write transaction was terminated by EOP.

Macros to access all of the registers are defined in `altera_avalon_sgdma_regs.h`. For example, this file includes macros to access the status register, including the following macros:

```
#define IOADDR_ALTERA_AVALON_SGDMA_STATUS(base)      __IO_CALC_ADDRESS_DYNAMIC(base, 0)
#define IORD_ALTERA_AVALON_SGDMA_STATUS(base)      IORD(base, 0)
#define IOWR_ALTERA_AVALON_SGDMA_STATUS(base, data) IOWR(base, 0, data)
#define ALTERA_AVALON_SGDMA_STATUS_ERROR_MSK (0x1)
#define ALTERA_AVALON_SGDMA_STATUS_ERROR_OFST (0)
#define ALTERA_AVALON_SGDMA_STATUS_EOP_ENCOUNTERED_MSK (0x2)
#define ALTERA_AVALON_SGDMA_STATUS_EOP_ENCOUNTERED_OFST (1)
```

For a complete list of predefined macros and utilities to access the SG-DMA Controller hardware, see:

- `<install_dir>\quartus\sopc_builder\components\altera_avalon_sgdma\inc\altera_avalon_sgdma_regs.h`,
- `<install_dir>\quartus\sopc_builder\components\altera_avalon_sgdma\HAL\inc\altera_avalon_sgdma.h`, and
- `<install_dir>\quartus\sopc_builder\components\altera_avalon_sgdma\HAL\inc\altera_avalon_sgdma_descriptor.h`.

## Timeouts

The SG-DMA controller does not implement internal counters to detect stalls. Software can instantiate a timer component if this functionality is required.

## SG-DMA Controller API

This section describes the application programming interface (API) for the SG-DMA controller core.

---

## alt\_avalon\_sgdma\_do\_async\_transfer()

- Prototype:** `int alt_avalon_do_async_transfer(alt_sgdma_dev *dev,  
alt_sgdma_descriptor *desc)`
- Thread-safe:** No.
- Available from ISR:** Yes.
- Include:** `<altera_avalon_sgdma.h>`, `<altera_avalon_sgdma_descriptor.h>`,  
`<altera_avalon_sgdma_regs.h>`
- Parameters:** `*dev`—a pointer to an SG-DMA device structure.  
`*desc`—a pointer to a single, constructed descriptor. The descriptor must have its "next" descriptor field initialized either to a non-ready descriptor, or to the next descriptor in the chain.
- Returns:** Returns 0 success. Other return codes are defined in `errno.h`.
- Description:** Set up and begin a non-blocking transfer of one or more descriptors or a descriptor chain. If the SG-DMA controller is busy at the time of this call, the routine will immediately return `-EBUSY`; the application can then decide how to proceed without being blocked. If a callback routine has been previously registered with this particular SG-DMA controller, the transfer will be set up to issue an interrupt on error, EOP, or chain completion. Otherwise, no interrupt is registered and it is the responsibility of the application developer to check for and handle errors and completion.

## alt\_avalon\_sgdma\_do\_sync\_transfer()

- Prototype:** `alt_u8 alt_avalon_sgdma_do_sync_transfer(alt_sgdma_dev *dev, alt_sgdma_descriptor *desc)`
- Thread-safe:** No.
- Available from ISR:** Not recommended.
- Include:** `<altera_avalon_sgdma.h>`, `<altera_avalon_sgdma_descriptor.h>`,  
`<altera_avalon_sgdma_regs.h>`
- Parameters:** `*dev`—a pointer to an SG-DMA device structure.  
`*desc`—a pointer to a single, constructed descriptor. The descriptor must have its "next" descriptor field initialized either to a non-ready descriptor, or to the next descriptor in the chain.
- Returns:** Returns the contents of the `status` register.
- Description:** Sends a fully formed descriptor or list of descriptors to the SG-DMA controller for transfer. This function blocks both before transfer, if the SG-DMA controller is busy, and until the requested transfer has completed. If an error is detected during the transfer, it is abandoned and the controller's `status` register contents are returned to the caller. Additional error information is available in the status bits of each descriptor that the SG-DMA processed. It is the responsibility of the user application to search through the descriptor or list of descriptors to gather specific error information.

## alt\_avalon\_sgdma\_construct\_mem\_to\_mem\_desc()

**Prototype:** void  
alt\_avalon\_sgdma\_construct\_mem\_to\_mem\_desc(alt\_sgdma\_descriptor \*desc, alt\_sgdma\_descriptor \*next, alt\_u32 \*read\_addr, alt\_u32 \*write\_addr, alt\_u16 length, int read\_fixed, int write\_fixed)

**Thread-safe:** Yes.

**Available from ISR:** Yes.

**Include:** <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>, <altera\_avalon\_sgdma\_regs.h>

**Parameters:** \*desc—a pointer to the descriptor being constructed.  
\*next—a pointer to the "next" descriptor. This does not need to be a complete or functional descriptor, but must be properly allocated.  
\*read\_addr—the first read address for the SG-DMA transfer.  
\*write\_addr—the first write address for the SG-DMA transfer.  
length—the number of bytes for the transfer.  
read\_fixed—if non-zero, the SG-DMA will read from a fixed address.  
write\_fixed—if non-zero, the SG-DMA will write to a fixed address.

**Returns:** void

**Description:** This function constructs a single SG-DMA descriptor in the memory specified in alt\_avalon\_sgdma\_descriptor \*desc for an Avalon-MM to Avalon-MM transfer. The function sets the OWNED\_BY\_HW bit in the descriptor's control field, marking the completed descriptor as ready to run. The descriptor is processed when the SG-DMA controller receives the descriptor and the RUN bit of the SG-DMA control register is asserted.

The next field of the descriptor being constructed is set to the address in \*next. The OWNED\_BY\_HW bit of the descriptor at \*next is explicitly cleared. Once the SG-DMA completes processing of the \*desc, it will not process the descriptor at \*next until its OWNED\_BY\_HW bit is set. To create a descriptor chain, you can repeatedly call this function using the previous call's \*next pointer in the \*desc parameter.

You are responsible for properly allocating memory for the creation of both the descriptor under construction as well as the next descriptor in the chain.

Descriptors must be in a memory device mastered by the SG-DMA controller's chain read and chain write Avalon master ports. Care must be taken to ensure that both \*desc and \*next point to areas of memory mastered by the controller.

## alt\_avalon\_sgdma\_construct\_stream\_to\_mem\_desc()

**Prototype:**           void  
                   alt\_avalon\_sgdma\_construct\_stream\_to\_mem\_desc(alt\_sgdma\_desc  
                   riptor \*desc, alt\_sgdma\_descriptor \*next, alt\_u32  
                   \*write\_addr, alt\_ul6 length\_or\_eop, int write\_fixed)

**Thread-safe:**        Yes.

**Available from ISR:** Yes.

**Include:**            <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>,  
                   <altera\_avalon\_sgdma\_regs.h>

**Parameters:**        \*desc—a pointer to the descriptor being constructed.  
                   \*next—a pointer to the "next" descriptor. This does not need to be a complete or  
                   functional descriptor, but must be properly allocated.  
                   \*write\_addr—the first write address for the SG-DMA transfer.  
                   length\_or\_eop—the number of bytes for the transfer. If set to zero (0x0), the transfer  
                   will continue until an EOP signal is received from the Avalon-ST interface.  
                   write\_fixed—if non-zero, the SG-DMA will write to a fixed address.

**Returns:**            void

**Description:**       This function constructs a single SG-DMA descriptor in the memory specified in  
                   alt\_avalon\_sgdma\_descriptor \*desc for an Avalon-ST to Avalon-MM transfer. The  
                   source (read) data for the transfer comes from the Avalon-ST interface connected to the  
                   SG-DMA controller's streaming read port.

The function sets the OWNED\_BY\_HW bit in the descriptor's control field, marking the  
 completed descriptor as ready to run. The descriptor is processed when the SG-DMA  
 controller receives the descriptor and the RUN bit of the SG-DMA control register is  
 asserted.

The next field of the descriptor being constructed is set to the address in \*next. The  
 OWNED\_BY\_HW bit of the descriptor at \*next is explicitly cleared. Once the SG-DMA  
 completes processing of the \*desc, it will not process the descriptor at \*next until its  
 OWNED\_BY\_HW bit is set. To create a descriptor chain, you can repeatedly call this  
 function using the previous call's \*next pointer in the \*desc parameter.

You are responsible for properly allocating memory for the creation of both the descriptor  
 under construction as well as the next descriptor in the chain.

Descriptors must be in a memory device mastered by the SG-DMA controller's chain  
 read and chain write Avalon master ports. Care must be taken to ensure that both  
 \*desc and \*next point to areas of memory mastered by the controller.

## alt\_avalon\_sgdma\_construct\_mem\_to\_stream\_desc()

**Prototype:** void  
alt\_avalon\_sgdma\_construct\_mem\_to\_stream\_desc(alt\_sgdma\_desc  
riptor \*desc, alt\_sgdma\_descriptor \*next, alt\_u32 \*read\_addr,  
alt\_ul6 length, int read\_fixed, int generate\_sop, int  
generate\_eop, alt\_u8 atlantic\_channel)

**Thread-safe:** Yes.

**Available from ISR:** Yes.

**Include:** <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>,  
<altera\_avalon\_sgdma\_regs.h>

**Parameters:** \*desc—a pointer to the descriptor being constructed.  
\*next—a pointer to the "next" descriptor. This does not need to be a complete or  
functional descriptor, but must be properly allocated.  
\*read\_addr—the first read address for the SG-DMA transfer.  
length—the number of bytes for the transfer.  
read\_fixed—if non-zero, the SG-DMA will read from a fixed address.  
generate\_sop—if non-zero, the SG-DMA will generate a start-of-packet (SOP) on the  
Avalon Streaming interface when commencing the transfer.  
generate\_eop—if non-zero, the SG-DMA will generate a end-of-packet (EOP) on the  
Avalon Streaming interface when completing the transfer.  
atlantic\_channel—an 8-bit channel identification number that will be passed to the  
Avalon-ST interface.

**Returns:** void

**Description:** This function constructs a single SG-DMA descriptor in the memory specified in  
alt\_avalon\_sgdma\_descriptor \*desc for an Avalon-MM to Avalon-ST transfer. The  
destination (write) data for the transfer goes to the Avalon-ST interface connected to the  
SG-DMA controller's streaming write port. The function sets the OWNED\_BY\_HW bit in  
the descriptor's control field, marking the completed descriptor as ready to run. The  
descriptor is processed when the SG-DMA controller receives the descriptor and the  
RUN bit of the SG-DMA control register is asserted.

The next field of the descriptor being constructed is set to the address in \*next. The  
OWNED\_BY\_HW bit of the descriptor at \*next is explicitly cleared. Once the SG-DMA  
completes processing of the \*desc, it will not process the descriptor at \*next until its  
OWNED\_BY\_HW bit is set. To create a descriptor chain, you can repeatedly call this  
function using the previous call's \*next pointer in the \*desc parameter.

You are responsible for properly allocating memory for the creation of both the descriptor  
under construction as well as the next descriptor in the chain. Descriptors must be in a  
memory device mastered by the SG-DMA controller's chain read and chain write Avalon  
master ports. Care must be taken to ensure that both \*desc and \*next point to areas  
of memory mastered by the controller.

## alt\_avalon\_sgdma\_check\_descriptor\_status()

**Prototype:**            int  
                          alt\_avalon\_sgdma\_check\_descriptor\_status(alt\_sgdma\_descriptor \*desc)

**Thread-safe:**        Yes.

**Available from ISR:** Yes.

**Include:**            <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>,  
                          <altera\_avalon\_sgdma\_regs.h>

**Parameters:**        \*desc—a pointer to the constructed descriptor to examine.

**Returns:**            Returns 0 if the descriptor is error-free, not owned by hardware, or a previously requested transfer completed normally. Other return codes are defined in **errno.h**.

**Description:**        Checks a descriptor previously owned by hardware for any errors reported in a previous transfer. The routine reports: errors reported by the SG-DMA controller, the buffer in use.

---

## alt\_avalon\_sgdma\_register\_callback()

**Prototype:**           void alt\_avalon\_sgdma\_register\_callback(alt\_sgdma\_dev \*dev,  
alt\_avalon\_sgdma\_callback callback, alt\_u16 chain\_control,  
void \*context)

**Thread-safe:**        Yes.

**Available from ISR:** Yes.

**Include:**            <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>,  
<altera\_avalon\_sgdma\_regs.h>

**Parameters:**        \*dev—a pointer to the SG-DMA device structure.  
callback—a pointer to the callback routine to execute at interrupt level.  
chain\_control—the SG-DMA control register contents.  
\*context—a pointer used to pass context-specific information to the  
ISR. context can point to any ISR-specific information.

**Returns:**            void

**Description:**       Associates a user-specific routine with the SG-DMA interrupt handler. If a callback is registered, all non-blocking transfers will enable interrupts that will cause the callback to be executed. The callback runs as part of the interrupt service routine, and great care must be taken to follow the guidelines for acceptable interrupt service routine behavior as described in the *Nios II Software Developer's Handbook*.

To disable callbacks after registering one, call this routine with 0x0 as the callback argument.

## alt\_avalon\_sgdma\_start()

- Prototype:** `void alt_avalon_sgdma_start (alt_sgdma_dev *dev)`
- Thread-safe:** No.
- Available from ISR:** Yes.
- Include:** `<altera_avalon_sgdma.h>`, `<altera_avalon_sgdma_descriptor.h>`,  
`<altera_avalon_sgdma_regs.h>`
- Parameters:** \*dev—a pointer to the SG-DMA device structure.
- Returns:** void
- Description:** Starts the DMA engine and processes the descriptor pointed to in the controller's next descriptor pointer and all subsequent descriptors in the chain. It is not necessary to call this function when `do_sync` or `do_async` is used.

---

## alt\_avalon\_sgdma\_stop()

**Prototype:** void alt\_avalon\_sgdma\_stop(alt\_sgdma\_dev \*dev)

**Thread-safe:** No.

**Available from ISR:** Yes.

**Include:** <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>, <altera\_avalon\_sgdma\_regs.h>

**Parameters:** \*dev—a pointer to the SG-DMA device structure.

**Returns:** void

**Description:** Stops the DMA engine following completion of the current buffer descriptor. It is not necessary to call this function when do\_sync or do\_async is used.

## alt\_avalon\_sgdma\_open()

- Prototype:** alt\_sgdma\_dev\* alt\_avalon\_sgdma\_open(const char\* name)
- Thread-safe:** Yes.
- Available from ISR:** No.
- Include:** <altera\_avalon\_sgdma.h>, <altera\_avalon\_sgdma\_descriptor.h>, <altera\_avalon\_sgdma\_regs.h>
- Parameters:** name—the name of the SG-DMA device to open.
- Returns:** A pointer to the SG-DMA device structure associated with the supplied name, or NULL if no corresponding SG-DMA device structure was found.
- Description:** Retrieves a pointer to a hardware SG-DMA device structure.

## Document Revision History

Table 6–13 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	<ul style="list-style-type: none"><li>• Chapter 6 was formerly Chapter 5.</li><li>• Updated the description for the following sections and APIs: Instantiating the Core in SOPC Builder, Software Control, DMA Descriptors, alt_avalon_sgdma_start() and alt_avalon_sgdma_stop()</li></ul>	—
May 2007 v7.1.0	Initial release.	—

## Core Overview

The direct memory access (DMA) controller core with Avalon® interface performs bulk data transfers, reading data from a source address range and writing the data to a different address range. An Avalon-MM master peripheral, such as a CPU, can offload memory transfer tasks to the DMA controller. While the DMA controller performs memory transfers, the master is free to perform other tasks in parallel.

The DMA controller transfers data as efficiently as possible, reading and writing data at the maximum pace allowed by the source or destination. The DMA controller is capable of performing Avalon transfers with flow control, enabling it to automatically transfer data to or from a slow peripheral with flow control (for example, a universal asynchronous receiver/transmitter [UART]), at the maximum pace allowed by the peripheral.

The DMA controller is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. For the Nios® II processor, device drivers are provided in the HAL system library. See [“Software Programming Model” on page 7-6](#) for details of HAL support.

This chapter contains the following sections:

- [“Functional Description”](#)
- [“Instantiating the Core in SOPC Builder” on page 7-4](#)
- [“Device and Tools Support” on page 7-6](#)
- [“Software Programming Model” on page 7-6](#)

## Functional Description

The DMA controller is used to perform direct memory-access data transfers from a source address-space to a destination address-space. The source and destination may be either an Avalon-MM slave peripheral (i.e., a constant address) or an address range in memory. The DMA controller can be used in conjunction with peripherals with flow control, which allows data transactions of fixed or variable length. The DMA controller can signal an interrupt request (IRQ) when a DMA transaction completes. A transaction is a sequence of one or more Avalon transfers initiated by the DMA controller core.

The DMA controller has two Avalon-MM master ports—a master read port and a master write port—and one Avalon-MM slave port for controlling the DMA as shown in [Figure 7-1](#).

**Figure 7-1. DMA Controller Block Diagram**

A typical DMA transaction proceeds as follows:

1. A CPU prepares the DMA controller for a transaction by writing to the control port.
2. The CPU enables the DMA controller. The DMA controller then begins transferring data without additional intervention from the CPU. The DMA's master read port reads data from the read address, which may be a memory or a peripheral. The master write port writes the data to the destination address, which can also be a memory or peripheral. A shallow FIFO buffers data between the read and write ports.
3. The DMA transaction ends when a specified number of bytes are transferred (i.e., a fixed-length transaction), or an end-of-packet signal is asserted by either the sender or receiver (in other words, a variable-length transaction). At the end of the transaction, the DMA controller generates an interrupt request (IRQ) if it was configured by the CPU to do so.
4. During or after the transaction, the CPU can determine if a transaction is in progress, or if the transaction ended (and how) by examining the DMA controller's status register.

## Setting Up DMA Transactions

An Avalon-MM master peripheral sets up and initiates DMA transactions by writing to registers via the control port. The Avalon-MM master programs the DMA engine using byte addresses which are byte aligned. The master peripheral configures the following options:

- Read (source) address location
- Write (destination) address location

- Size of the individual transfers: Byte (8-bit), halfword (16-bit), word (32-bit), doubleword (64-bit) or quadword (128-bit)
- Enable interrupt upon end of transaction
- Enable source or destination to end the DMA transaction with end-of-packet signal
- Specify whether source and destination are memory or peripheral

The master peripheral then sets a bit in the `control` register to initiate the DMA transaction.

## The Master Read and Write Ports

The DMA controller reads data from the source address through the master read port, and then writes to the destination address through the master write port. The DMA controller is programmed using byte addresses. Read and write start addresses should be aligned to the transfer size. For example, to transfer data words, if the start address is 0, the address will increment to 4, 8 and 12. For heterogeneous systems where a number of different slave devices are of different widths, the data width for read and write masters matches the width of the widest data-width slave addressed by either the read or the write master. For bursting transfers, the burst length is set to the DMA transaction length with the appropriate unit conversion. For example, if a 32-bit data width DMA is programmed for a word transfer of 64 bytes, the length registered is programmed with 64 and the burst count port will be 16. If a 64-bit data width DMA is programmed for a doubleword transfer of 8 bytes, the length register is programmed with 8 and the burst count port will be 1.

There is a shallow FIFO buffer between the master read and write ports. The default depth is 2, which makes the write action depend on the data-available status of the FIFO, rather than on the status of the master read port.

Both the read and write master ports are capable of performing Avalon transfers with flow control, which allows the slave peripheral to control the flow of data and terminate the DMA transaction.

For details about flow control in Avalon-MM data transfers and Avalon-MM peripherals, refer to the *Avalon Memory-Mapped Interface Specification*.

## Addressing and Address Incrementing

When accessing memory, the read (or write) address increments by 1, 2, 4, 8 or 16 after each access, depending on the width of the data. On the other hand, a typical peripheral device (such as UART) has fixed register locations. In this case, the read/write address is held constant throughout the DMA transaction.

The rules for address incrementing are, in order of priority:

- If the `control` register's `RCON` (or `WCON`) bit is set, the read (or write) increment value is 0.
- Otherwise, the read and write increment values are set according to the transfer size specified in the control register, as shown in [Table 7-1](#).

Transfer Width	Increment
byte	1
halfword	2
word	4
doubleword	8
quadword	16

In systems with heterogeneous data widths, care must be taken to present the correct address or offset when configuring the DMA to access native-aligned slaves. For example, in a system using a 32-bit Nios II processor and a 16-bit DMA, the base address for the UART `txdata` register must be divided by the `dma_data_width/cpu_data_width—2` in this example.

## Instantiating the Core in SOPC Builder

Use the MegaWizard® interface for the DMA controller in SOPC Builder to specify the core's configuration. Instantiating the DMA controller in SOPC Builder creates one slave port and two master ports. You must specify which slave peripherals can be accessed by the read and write master ports. Likewise, you must specify which other master peripheral(s) can access the DMA control port and initiate DMA transactions. The DMA controller does not export any signals to the top level of the system module.

## DMA Parameters (Basic)

This section describes the parameters you can configure on the **DMA Parameters** page.

### *Transfer Size*

The parameter **Width of the DMA Length Register** specifies the minimum width of the DMA's transaction length register, which can be between 1 and 32. The `length` register determines the maximum number of transfers possible in a single DMA transaction.

By default, the length register is wide enough to span any of the slave peripherals mastered by the read or write ports. Overriding the length register may be necessary if the DMA master port (read or write) masters only data peripherals, such as a UART. In this case, the address span of each slave is small, but a larger number of transfers may be desired per DMA transaction.

### *Burst Transactions*

When **Enable Burst Transfers** is turned on, the DMA controller performs burst transactions on its master read and write ports. The parameter **Maximum Burst Size** determines the maximum burst size allowed in a transaction.

In burst mode, the length of a transaction must not be longer than the configured maximum burst size. Otherwise, the transaction must be performed as multiple transactions.

### *FIFO Implementation*

This option determines the implementation of the FIFO buffer between the master read and write ports. Select **Construct FIFO from Registers** to implement the FIFO using one register per storage bit. This has a strong impact on logic utilization when the DMA controller's data width is large. See ["Advanced Options" on page 7-6](#).

To implement the FIFO using embedded memory blocks available in the FPGA, select **Construct FIFO from Memory Blocks**.

## Advanced Options

This section describes the parameters you can configure on the **Advanced Options** page.

### *Allowed Transactions*

You can choose the transfer datawidth(s) supported by the DMA controller hardware. The following datawidth options can be enabled or disabled:

- Byte
- Halfword (two bytes)
- Word (four bytes)
- Doubleword (eight bytes)
- Quadword (sixteen bytes)

Disabling unnecessary transfer widths reduces the amount of on-chip logic resources consumed by the DMA controller core. For example, if a system has both 16-bit and 32-bit memories, but the DMA controller will only transfer data to the 16-bit memory, then 32-bit transfers could be disabled to conserve logic resources.

## Device and Tools Support

The DMA Controller Core with Avalon Interface supports all Altera FPGA families.

## Software Programming Model

This section describes the programming model for the DMA controller, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the DMA controller core using the HAL API for DMA devices.

### HAL System Library Support

The Altera-provided driver implements a HAL DMA device driver that integrates into the HAL system library for Nios II systems. HAL users should access the DMA controller via the familiar HAL API, rather than accessing the registers directly.

If your program uses the HAL device driver to access the DMA controller, accessing the device registers directly will interfere with the correct behavior of the driver.

The HAL DMA driver provides both ends of the DMA process; the driver registers itself as both a receive channel (`alt_dma_rxchan`) and a transmit channel (`alt_dma_txchan`). The *Nios II Software Developer's Handbook* provides complete details of the HAL system library and the usage of DMA devices.

### *ioctl() Operations*

`ioctl()` operation requests are defined for both the receive and transmit channels, which allows you to control the hardware-dependent aspects of the DMA controller. Two `ioctl()` functions are defined for the receiver driver and the transmitter driver: `alt_dma_rxchan_ioctl()` and `alt_dma_txchan_ioctl()`. Table 7-2 lists the available operations. These are valid for both the transmit and receive channels.

<b>Request</b>	<b>Meaning</b>
<code>ALT_DMA_SET_MODE_8</code>	Transfers data in units of 8 bits. The value of "arg" is ignored.
<code>ALT_DMA_SET_MODE_16</code>	Transfers data in units of 16 bits. The value of "arg" is ignored.
<code>ALT_DMA_SET_MODE_32</code>	Transfers data in units of 32 bits. The value of "arg" is ignored.
<code>ALT_DMA_SET_MODE_64</code>	Transfers data in units of 64 bits. The value of "arg" is ignored.
<code>ALT_DMA_SET_MODE_128</code>	Transfers data in units of 128 bits. The value of "arg" is ignored.
<code>ALT_DMA_RX_ONLY_ON (1)</code>	Sets a DMA receiver into streaming mode. In this case, data is read continuously from a single location. The "arg" parameter specifies the address to read from.
<code>ALT_DMA_RX_ONLY_OFF (1)</code>	Turns off streaming mode for a receive channel. The value of "arg" is ignored.
<code>ALT_DMA_TX_ONLY_ON (1)</code>	Sets a DMA transmitter into streaming mode. In this case, data is written continuously to a single location. The "arg" parameter specifies the address to write to.
<code>ALT_DMA_TX_ONLY_OFF (1)</code>	Turns off streaming mode for a transmit channel. The value of "arg" is ignored.

**Note to Table 7-2:**

- (1) These macro names changed in version 1.1 of the Nios II Embedded Design Suite (EDS). The old names (`ALT_DMA_TX_STREAM_ON`, `ALT_DMA_TX_STREAM_OFF`, `ALT_DMA_RX_STREAM_ON`, and `ALT_DMA_RX_STREAM_OFF`) are still valid, but new designs should use the new names.

### *Limitations*

Currently the Altera-provided drivers do not support 64-bit and 128-bit DMA transactions.

This function is not thread safe. If you want to access the DMA controller from more than one thread then you should use a semaphore or mutex to ensure that only one thread is executing within this function at any time.

## Software Files

The DMA controller is accompanied by the following software files. These files define the low-level interface to the hardware. Application developers should not modify these files.

- **altera\_avalon\_dma\_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- **altera\_avalon\_dma.h, altera\_avalon\_dma.c**—These files implement the DMA controller's device driver for the HAL system library.

## Register Map

Programmers using the HAL API never access the DMA controller hardware directly via its registers. In general, the register map is only useful to programmers writing a device driver.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 7-3 shows the register map for the DMA controller. Device drivers control and communicate with the hardware through five memory-mapped 32-bit registers.

Offset	Register Name	Read/Write	31 . . 13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	status (1)	RW	(2)									LEN	WEOP	REOP	BUSY	DONE
1	readaddress	RW	Read master start address													
2	writeaddress	RW	Write master start address													
3	length	RW	DMA transaction length (in bytes)													
4	—	—	Reserved (3)													
5	—	—	Reserved (3)													
6	control	RW	(2)	SOFTWARERESET	QUADWORD	DOUBLEWORD	WCON	RCON	LEEN	WEEN	REEN	L_LEN	GO	WORD	HW	BYTE
7	—	—	Reserved (3)													

**Notes to Table 7-3:**

- (1) Writing zero to the status register clears the LEN, WEOP, REOP, and DONE bits.
- (2) These bits are reserved. Read values are undefined. Write zero.
- (3) This register is reserved. Read values are undefined. The result of a write is undefined.

### status Register

The status register consists of individual bits that indicate conditions inside the DMA controller. The status register can be read at any time. Reading the status register does not change its value.

The status register bits are shown in [Table 7-4](#).

Bit Number	Bit Name	Read/Write/Clear	Description
0	DONE	R/C	A DMA transaction is completed. The DONE bit is set to 1 when an end of packet condition is detected or the specified transaction length is completed. Write zero to the status register to clear the DONE bit.
1	BUSY	R	The BUSY bit is 1 when a DMA transaction is in progress.
2	REOP	R	The REOP bit is 1 when a transaction is completed due to an end-of-packet event on the read side.
3	WEOP	R	The WEOP bit is 1 when a transaction is completed due to an end of packet event on the write side.
4	LEN	R	The LEN bit is set to 1 when the length register decrements to zero.

#### *readaddress Register*

The *readaddress* register specifies the first location to be read in a DMA transaction. The *readaddress* register width is determined at system generation time. It is wide enough to address the full range of all slave ports mastered by the read port.

#### *writeaddress Register*

The *writeaddress* register specifies the first location to be written in a DMA transaction. The *writeaddress* register width is determined at system generation time. It is wide enough to address the full range of all slave ports mastered by the write port.

#### *length Register*

The *length* register specifies the number of bytes to be transferred from the read port to the write port. The *length* register is specified in bytes. For example, the value must be a multiple of 4 for word transfers, and a multiple of 2 for halfword transfers.

The *length* register is decremented as each data value is written by the write master port. When *length* reaches 0 the LEN bit is set. The *length* register does not decrement below 0.

The *length* register width is determined at system generation time. It is at least wide enough to span any of the slave ports mastered by the read or write master ports, and it can be made wider if necessary.

*control Register*

The control register is composed of individual bits that control the DMA's internal operation. The control register's value can be read at any time. The control register bits determine which, if any, conditions of the DMA transaction result in the end of a transaction and an interrupt request.

The control register bits are shown in [Table 7-5](#).

<b>Bit Number</b>	<b>Bit Name</b>	<b>Read/Write/Clear</b>	<b>Description</b>
0	BYTE	RW	Specifies byte transfers.
1	HW	RW	Specifies halfword (16-bit) transfers.
2	WORD	RW	Specifies word (32-bit) transfers.
3	GO	RW	Enables DMA transaction. When the GO bit is set to 0, the DMA is prevented from executing transfers. When the GO bit is set to 1 and the length register is non-zero, transfers occur.
4	I_EN	RW	Enables interrupt requests (IRQ). When the I_EN bit is 1, the DMA controller generates an IRQ when the status register's DONE bit is set to 1. IRQs are disabled when the I_EN bit is 0.
5	REEN	RW	Ends transaction on read-side end-of-packet. When the REEN bit is set to 1, a slave port with flow control on the read side may end the DMA transaction by asserting its end-of-packet signal.
6	WEEN	RW	Ends transaction on write-side end-of-packet. When the WEEN bit is set to 1, a slave port with flow control on the write side may end the DMA transaction by asserting its end-of-packet signal.
7	LEEN	RW	Ends transaction when the length register reaches zero. When the LEEN bit is 1, the DMA transaction ends when the length register reaches 0. When this bit is 0, length reaching 0 does not cause a transaction to end. In this case, the DMA transaction must be terminated by an end-of-packet signal from either the read or write master port.

**Table 7–5. control Register Bits (Part 2 of 2)**

Bit Number	Bit Name	Read/Write/Clear	Description
8	RCON	RW	Reads from a constant address. When RCON is 0, the read address increments after every data transfer. This is the mechanism for the DMA controller to read a range of memory addresses. When RCON is 1, the read address does not increment. This is the mechanism for the DMA controller to read from a peripheral at a constant memory address. For details, see <a href="#">“Addressing and Address Incrementing” on page 7–4.</a>
9	WCON	RW	Writes to a constant address. Similar to the RCON bit, when WCON is 0 the write address increments after every data transfer; when WCON is 1 the write address does not increment. For details, see <a href="#">“Addressing and Address Incrementing” on page 7–4.</a>
10	DOUBLEWORD	RW	Specifies doubleword transfers.
11	QUADWORD	RW	Specifies quadword transfers.
12	SOFTWARERESET	RW	Software can reset the DMA engine by writing this bit to 1 twice. Upon the second write of 1 to the SOFTWARERESET bit, the DMA control will be reset identically to a system reset. The logic which sequences the software reset process then resets itself automatically.

The data width of DMA transactions is specified by the BYTE, HW, WORD, DOUBLEWORD, and QUADWORD bits. Only one of these bits can be set at a time. If more than one of the bits is set, the DMA controller behavior is undefined. The width of the transfer is determined by the narrower of the two slaves read and written. For example, a DMA transaction that reads from a 16-bit flash memory and writes to a 32-bit on-chip memory requires a halfword transfer. In this case, HW must be set to 1, and BYTE, WORD, DOUBLEWORD, and QUADWORD must be set to 0.

To successfully perform transactions of a specific width, that width must be enabled in hardware using the **Allowed Transaction** hardware option. For example, the DMA controller behavior is undefined if quadword transfers are disabled in hardware, but the QUADWORD bit is set during a DMA transaction.

Executing a DMA software reset when a DMA transfer is active may result in permanent bus lockup (until the next system reset). The SOFTWARERESET bit should therefore not be written except as a last resort.

## Interrupt Behavior

The DMA controller has a single IRQ output that is asserted when the `status` register's `DONE` bit equals 1 and the control register's `I_EN` bit equals 1.

Writing the `status` register clears the `DONE` bit and acknowledges the IRQ. A master peripheral can read the `status` register and determine how the DMA transaction finished by checking the `LEN`, `REOP`, and `WEOP` bits.

## Referenced Document

This chapter references the [Avalon Memory-Mapped Interface Specification](#) manual.

## Document Revision History

---

This section describes communication peripherals provided by Altera. These components provide communication interfaces for SOPC Builder systems.

See *About This Handbook* for further details.

This section includes the following chapters:

- Chapter 8, JTAG UART Core
- Chapter 9, UART Core
- Chapter 10, SPI Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

### Core Overview

The JTAG universal asynchronous receiver/transmitter (UART) core with Avalon<sup>®</sup> interface implements a method to communicate serial character streams between a host PC and an SOPC Builder system on an Altera<sup>®</sup> FPGA. In many designs, the JTAG UART core eliminates the need for a separate RS-232 serial connection to a host PC for character I/O. The core provides a simple register-mapped Avalon interface that hides the complexities of the JTAG interface from embedded software programmers. Master peripherals (such as a Nios<sup>®</sup> II processor) communicate with the core by reading and writing control and data registers.

The JTAG UART core uses the JTAG circuitry built in to Altera FPGAs, and provides host access via the JTAG pins on the FPGA. The host PC can connect to the FPGA via any Altera JTAG download cable, such as the USB-Blaster<sup>™</sup> cable. Software support for the JTAG UART core is provided by Altera. For the Nios II processor, device drivers are provided in the HAL system library, allowing software to access the core using the ANSI C Standard Library `stdio.h` routines. For the host PC, Altera provides JTAG terminal software that manages the connection to the target, decodes the JTAG data stream, and displays characters on screen.

The JTAG UART core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- “Functional Description” on page 8-2
- “Device and Tools Support” on page 8-4
- “Instantiating the Core in SOPC Builder” on page 8-4
- “Hardware Simulation Considerations” on page 8-7
- “Software Programming Model” on page 8-7

## Functional Description

Figure 8–1 shows a block diagram of the JTAG UART core and its connection to the JTAG circuitry inside an Altera FPGA. The following sections describe the components of the core.

Figure 8–1. JTAG UART Core Block Diagram

### Avalon Slave Interface and Registers

The JTAG UART core provides an Avalon slave interface to the JTAG circuitry on an Altera FPGA. The user-visible interface to the JTAG UART core consists of two 32-bit registers, `data` and `control`, that are accessed through an Avalon slave port. An Avalon master, such as a Nios II processor, accesses the registers to control the core and transfer data over the JTAG connection. The core operates on 8-bit units of data at a time; eight bits of the `data` register serve as a one-character payload.

The JTAG UART core provides an active-high interrupt output that can request an interrupt when read data is available, or when the write FIFO is ready for data. For further details see “[Interrupt Behavior](#)” on [page 8–13](#).

## Read and Write FIFOs

The JTAG UART core provides bidirectional FIFOs to improve bandwidth over the JTAG connection. The FIFO depth is parameterizable to accommodate the available on-chip memory. The FIFOs can be constructed out of memory blocks or registers, allowing you to trade off logic resources for memory resources, if necessary.

## JTAG Interface

Altera FPGAs contain built-in JTAG control circuitry between the device's JTAG pins and the logic inside the device. The JTAG controller can connect to user-defined circuits called "nodes" implemented in the FPGA. Because several nodes may need to communicate via the JTAG interface, a JTAG hub (that is, a multiplexer) is necessary. During logic synthesis and fitting, the Quartus® II software automatically generates the JTAG hub logic. No manual design effort is required to connect the JTAG circuitry inside the device; the process is presented here only for clarity.

## Host-Target Connection

Figure 8–2 shows the connection between a host PC and an SOPC Builder-generated system containing a JTAG UART core.

Figure 8–2. Example System Using the JTAG UART Core

The JTAG controller on the FPGA and the download cable driver on the host PC implement a simple data-link layer between host and target. All JTAG nodes inside the FPGA are multiplexed through the single JTAG connection. JTAG server software on the host PC controls and decodes the JTAG data stream, and maintains distinct connections with nodes inside the FPGA.

The example system in [Figure 8–2](#) contains one JTAG UART core and a Nios II processor. Both agents communicate with the host PC over a single Altera download cable. Thanks to the JTAG server software, each host application has an independent connection to the target. Altera provides the JTAG server drivers and host software required to communicate with the JTAG UART core.

Systems with multiple JTAG UART cores are possible, and all cores communicate via the same JTAG interface. To maintain coherent data streams, only one processor should communicate with each JTAG UART core.

## Device and Tools Support

The JTAG UART core supports the Arria™ GX, Stratix® III, Stratix II, Stratix II GX, Stratix GX, Stratix, Cyclone® III, Cyclone II, and Cyclone device families. The JTAG UART core is supported by the Nios II hardware abstraction layer (HAL) system library. No software support is provided for the first-generation Nios processor.

To view the character stream on the host PC, the JTAG UART core must be used in conjunction with the JTAG terminal software provided by Altera. Nios II processor users access the JTAG UART via the Nios II IDE or the **nios2-terminal** command-line utility.

For further details, refer to the *Nios II Software Developer's Handbook* or the Nios II IDE online help

## Instantiating the Core in SOPC Builder

Designers use the MegaWizard® interface for the JTAG UART core in SOPC Builder to specify the core features. The following sections describe the available options in the MegaWizard interface.

### Configuration Page

The options on this page control the hardware configuration of the JTAG UART core. The default settings are pre-configured to behave optimally with the Altera-provided device drivers and JTAG terminal software. Most designers should not change the default values, except for the **Construct using registers instead of memory blocks** option.

### *Write FIFO Settings*

The write FIFO buffers data flowing from the Avalon interface to the host. The following settings are available:

- **Depth**—The write FIFO depth can be set from 8 to 32,768 bytes. Only powers of two are allowed. Larger values consume more on-chip memory resources. A depth of 64 is generally optimal for performance, and larger values are rarely necessary.
- **IRQ Threshold**—The write IRQ threshold governs how the core asserts its IRQ in response to the FIFO emptying. As the JTAG circuitry empties data from the write FIFO, the core asserts its IRQ when the number of characters remaining in the FIFO reaches this threshold value. For maximum bandwidth, a processor should service the interrupt by writing more data and preventing the write FIFO from emptying completely. A value of 8 is typically optimal. See [“Interrupt Behavior” on page 8–13](#) for further details.
- **Construct using registers instead of memory blocks**—Turning on this option causes the FIFO to be constructed out of on-chip logic resources. This option is useful when memory resources are limited. Each byte consumes roughly 11 logic elements (LEs), so a FIFO depth of 8 (bytes) consumes roughly 88 LEs.

### *Read FIFO Settings*

The read FIFO buffers data flowing from the host to the Avalon interface. Settings are available to control the depth of the FIFO and the generation of interrupts.

- **Depth**—The read FIFO depth can be set from 8 to 32,768 bytes. Only powers of two are allowed. Larger values consume more on-chip memory resources. A depth of 64 is generally optimal for performance, and larger values are rarely necessary.
- **IRQ Threshold**—The IRQ threshold governs how the core asserts its IRQ in response to the FIFO filling up. As the JTAG circuitry fills up the read FIFO, the core asserts its IRQ when the amount of space remaining in the FIFO reaches this threshold value. For maximum bandwidth, a processor should service the interrupt by reading data and preventing the read FIFO from filling up completely. A value of 8 is typically optimal. See [“Interrupt Behavior” on page 8–13](#) for further details.

- **Construct using registers instead of memory blocks**—Turning on this option causes the FIFO to be constructed out of logic resources. This option is useful when memory resources are limited. Each byte consumes roughly 11 LEs, so a FIFO depth of 8 (bytes) consumes roughly 88 LEs.

## Simulation Settings

At system generation time, when SOPC Builder generates the logic for the JTAG UART core, a simulation model is also constructed. The simulation model offers features to simplify simulation of systems using the JTAG UART core. Changes to the simulation settings do not affect the behavior of the core in hardware; the settings affect only functional simulation.

### *Simulated Input Character Stream*

You can enter a character stream that will be simulated entering the read FIFO upon simulated system reset. The MegaWizard interface accepts an arbitrary character string, which is later incorporated into the test bench. After reset, this character string is pre-initialized in the read FIFO, giving the appearance that an external JTAG terminal program is sending a character stream to the JTAG UART core.

### *Prepare Interactive Windows*

At system generation time, the JTAG UART core generator can create ModelSim<sup>®</sup> macros to open interactive windows during simulation. These windows allow the user to send and receive ASCII characters via a console, giving the appearance of a terminal session with the system executing in hardware. The following options are available:

- **Do not generate ModelSim aliases for interactive windows**—This option does not create any ModelSim macros for character I/O.
- **Create ModelSim alias to open a window showing output as ASCII text**—This option creates a ModelSim macro to open a console window that displays output from the write FIFO. Values written to the write FIFO via the Avalon interface are displayed in the console as ASCII characters.
- **Create ModelSim alias to open an interactive stimulus/response window**—This option creates a ModelSim macro to open a console window that allows input and output interaction with the core. Values written to the write FIFO via the Avalon interface are displayed in the console as ASCII characters. Characters typed into

the console are fed into the read FIFO, and can be read via the Avalon interface. When this option is enabled, the simulated character input stream option is ignored.

## Hardware Simulation Considerations

The simulation features were created for easy simulation of Nios II processor systems when using the ModelSim simulator. The simulation model is implemented in the JTAG UART core's top-level HDL file. The synthesizable HDL and the simulation HDL are implemented in the same file. Some simulation features are implemented using "translate on/off" synthesis directives that make certain sections of HDL code visible only to the synthesis tool.

Refer to *AN 351: Simulating Nios II Processor Designs* for complete details about simulating the JTAG UART core in Nios II systems.

Other simulators can be used, but require user effort to create a custom simulation process. You can use the auto-generated ModelSim scripts as references to create similar functionality for other simulators.

Do not edit the simulation directives if you are using Altera's recommended simulation procedures. If you change the simulation directives to create a custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precautions to ensure your changes are not overwritten.

## Software Programming Model

The following sections describe the software programming model for the JTAG UART core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides HAL system library drivers that enable you to access the JTAG UART using the ANSI C standard library functions, such as `printf()` and `getchar()`.

### HAL System Library Support

The Altera-provided driver implements a HAL character-mode device driver that integrates into the HAL system library for Nios II systems. HAL users should access the JTAG UART via the familiar HAL API and the ANSI C standard library, rather than accessing the JTAG UART registers. `ioctl()` requests are defined that allow HAL users to control the hardware-dependent aspects of the JTAG UART.

If your program uses the Altera-provided HAL device driver to access the JTAG UART hardware, accessing the device registers directly will interfere with the correct behavior of the driver.

For Nios II processor users, the HAL system library API provides complete access to the JTAG UART core's features. Nios II programs treat the JTAG UART core as a character mode device, and send and receive data using the ANSI C standard library functions, such as `getchar()` and `printf()`.

**Example 8-1** demonstrates the simplest possible usage, printing a message to `stdout` using `printf()`. In this example, the SOPC Builder system contains a JTAG UART core, and the HAL system library is configured to use this JTAG UART device for `stdout`.

---

**Example 8-1. Printing Characters to a JTAG UART Core as `stdout`**

```
#include <stdio.h>
int main ()
{
    printf("Hello world.\n");
    return 0;
}
```

---

**Example 8-2** demonstrates reading characters from and sending messages to a JTAG UART core using the C standard library. In this example, the SOPC Builder system contains a JTAG UART core named `jtag_uart` that is not necessarily configured as the `stdout` device. In this case, the program treats the device like any other node in the HAL file system.

---

**Example 8–2. Transmitting Characters to a JTAG UART Core**

```
/* A simple program that recognizes the characters 't' and 'v' */
#include <stdio.h>
#include <string.h>
int main ()
{
    char* msg = "Detected the character 't'.\n";
    FILE* fp;
    char prompt = 0;

    fp = fopen ("/dev/jtag_uart", "r+"); //Open file for reading and writing
    if (fp)
    {
        while (prompt != 'v')
        { // Loop until we receive a 'v'.
            prompt = getc(fp); // Get a character from the JTAG UART.
            if (prompt == 't')
            { // Print a message if character is 't'.
                fwrite (msg, strlen (msg), 1, fp);
            }

            if (ferror(fp))// Check if an error occurred with the file pointer
                clearerr(fp);// If so, clear it.
        }

        fprintf(fp, "Closing the JTAG UART file handle.\n");
        fclose (fp);
    }

    return 0;
}
```

---

In this example, the `ferror (fp)` is used to check if an error occurred on the JTAG UART connection, such as a disconnected JTAG connection. In this case, the driver detects that the JTAG connection is disconnected, reports an error (EIO), and discards data for subsequent transactions. If this error ever occurs, the C library latches the value until you explicitly clear it with the `clearerr ()` function.

The *Nios II Software Developer's Handbook* provides complete details of the HAL system library. The Nios II Embedded Design Suite (EDS) provides a number of software example designs that use the JTAG UART core.

### *Driver Options: Fast versus Small Implementations*

To accommodate the requirements of different types of systems, the JTAG UART driver has two variants, a fast version and a small version. The fast behavior is used by default. Both the fast and small drivers fully support the C standard library functions and the HAL API.

The fast driver is an interrupt-driven implementation, which allows the processor to perform other tasks when the device is not ready to send or receive data. Because the JTAG UART data rate is slow compared to the processor, the fast driver can provide a large performance benefit for systems that could be performing other tasks in the interim. In addition, the fast version of the Altera Avalon JTAG UART monitors the connection to the host. The driver discards characters if no host is connected, or if the host is not running an application that handles the I/O stream.

The small driver is a polled implementation that waits for the JTAG UART hardware before sending and receiving each character. The performance of the small driver is poor if you are sending large amounts of data. The small version assumes that the host is always connected, and will never discard characters. Therefore, the small driver will hang the system if the JTAG UART hardware is ever disconnected from the host while the program is sending or receiving data. There are two ways to enable the small footprint driver:

- Enable the small footprint setting for the HAL system library project. This option affects device drivers for all devices in the system.
- Specify the preprocessor option `-DALTERA_AVALON_JTAG_UART_SMALL`. Use this option if you want the small, polled implementation of the JTAG UART driver, but you do not want to affect the drivers for other devices.

### *ioctl() Operations*

The fast version of the JTAG UART driver supports the `ioctl()` function to allow HAL-based programs to request device-specific operations. Specifically, you can use the `ioctl()` operations to control the timeout period, and to detect whether or not a host is connected. The fast driver defines the `ioctl()` operations shown in [Table 8-1](#).

<b>Table 8-1. JTAG UART ioctl() Operations for the Fast Driver Only</b>	
<b>Request</b>	<b>Meaning</b>
TIOCTIMEOUT	Set the timeout (in seconds) after which the driver will decide that the host is not connected. A timeout of 0 makes the target assume that the host is always connected. The <code>ioctl</code> arg parameter passed in must be a pointer to an integer.
TIOCGCONNECTED	Sets the integer arg parameter to a value that indicates whether the host is connected and acting as a terminal (1), or not connected (0). The <code>ioctl</code> arg parameter passed in must be a pointer to an integer.

For details about the `ioctl()` function, refer to the *Nios II Software Developer's Handbook*.

## Software Files

The JTAG UART core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- **altera\_avalon\_jtag\_uart\_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- **altera\_avalon\_jtag\_uart.h, altera\_avalon\_jtag\_uart.c**—These files implement the HAL system library device driver.

## Accessing the JTAG UART Core via a Host PC

Host software is necessary for a PC to access the JTAG UART core. The Nios II IDE supports the JTAG UART core, and displays character I/O in a console window. Altera also provides a command-line utility called **nios2-terminal** that opens a terminal session with the JTAG UART core.

For further details, refer to the *Nios II Software Developer's Handbook* and the Nios II IDE online help.

## Register Map

Programmers using the HAL API never access the JTAG UART core directly via its registers. In general, the register map is only useful to programmers writing a device driver for the core.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 8–2 shows the register map for the JTAG UART core. Device drivers control and communicate with the core through the two 32-bit memory-mapped registers.

Offset	Register Name	R/W	Bit Description																
			31	...	16	15	14	...	11	10	9	8	7	...	2	1	0		
0	data	RW	RAVAIL			RVALID		(1)						DATA					
1	control	RW	WSPACE			(1)				AC	WI	RI	(1)		WE	RE			

Note to Table 8–2:

(1) Reserved. Read values are undefined. Write zero.

### Data Register

Embedded software accesses the read and write FIFOs via the data register. Table 8–3 describes the function of each bit.

Bit Number	Bit/Field Name	Read/Write/Clear	Description
0 .. 7	DATA	R/W	The value to transfer to/from the JTAG core. When writing, the DATA field holds a character to be written to the write FIFO. When reading, the DATA field holds a character read from the read FIFO.
15	RVALID	R	Indicates whether the DATA field is valid. If RVALID=1, then the DATA field is valid, otherwise DATA is undefined.
16 .. 32	RAVAIL	R	The number of characters remaining in the read FIFO (after the current read).

A read from the data register returns the first character from the FIFO (if one is available) in the DATA field. Reading also returns information about the number of characters remaining in the FIFO in the RAVAIL field. A write to the data register stores the value of the DATA field in the write FIFO. If the write FIFO is full, then the character is lost.

### Control Register

Embedded software controls the JTAG UART core's interrupt generation and reads status information via the `control` register. [Table 8-4](#) describes the function of each bit.

Bit Number	Bit/Field Name	Read/Write/Clear	Description
0	RE	R/W	Interrupt-enable bit for read interrupts
1	WE	R/W	Interrupt-enable bit for write interrupts
8	RI	R	Indicates that the read interrupt is pending
9	WI	R	Indicates that the write interrupt is pending
10	AC	R/C	Indicates that there has been JTAG activity since the bit was cleared. Writing 1 to AC clears it to 0.
16 .. 32	WSPACE	R	The number of spaces available in the <code>write</code> FIFO.

A read from the `control` register returns the status of the `read` and `write` FIFOs. Writes to the register can be used to enable/disable interrupts, or clear the AC bit.

The RE and WE bits enable interrupts for the read and write FIFOs, respectively. The WI and RI bits indicate the status of the interrupt sources, qualified by the values of the interrupt enable bits (WE and RE). Embedded software can examine RI and WI to determine the condition that generated the IRQ. See [“Interrupt Behavior” on page 8-13](#) for further details.

The AC bit indicates that an application on the host PC has polled the JTAG UART core via the JTAG interface. Once set, the AC bit remains set until it is explicitly cleared via the Avalon interface. Writing 1 to AC clears it. Embedded software can examine the AC bit to determine if a connection exists to a host PC. If no connection exists, the software may choose to ignore the JTAG data stream. When the host PC has no data to transfer, it can choose to poll the JTAG UART core as infrequently as once per second. Delays caused by other host software using the JTAG download cable could cause delays of up to 10 seconds between polls.

### Interrupt Behavior

The JTAG UART core generates an interrupt when either of the individual interrupt conditions is pending and enabled.

Interrupt behavior is of interest to device driver programmers concerned with the bandwidth performance to the host PC. Example designs and the JTAG terminal program provided with Nios II Embedded Design Suite (EDS) are pre-configured with optimal interrupt behavior.

The JTAG UART core has two kinds of interrupts: write interrupts and read interrupts. The WE and RE bits in the `control` register enable/disable the interrupts.

The core can assert a write interrupt whenever the write FIFO is nearly empty. The “nearly empty” threshold, `write_threshold`, is specified at system generation time and cannot be changed by embedded software. The write interrupt condition is set whenever there are `write_threshold` or fewer characters in the write FIFO. It is cleared by writing characters to fill the write FIFO beyond the `write_threshold`. Embedded software should only enable write interrupts after filling the write FIFO. If it has no characters remaining to send, embedded software should disable the write interrupt.

The core can assert a read interrupt whenever the read FIFO is nearly full. The “nearly full” threshold value, `read_threshold`, is specified at system generation time and cannot be changed by embedded software. The read interrupt condition is set whenever the read FIFO has `read_threshold` or fewer spaces remaining. The read interrupt condition is also set if there is at least one character in the read FIFO and no more characters are expected. The read interrupt is cleared by reading characters from the read FIFO.

For optimum performance, the interrupt thresholds should match the interrupt response time of the embedded software. For example, with a 10-MHz JTAG clock, a new character is provided (or consumed) by the host PC every 1 $\mu$ s. With a threshold of 8, the interrupt response time must be less than 8 $\mu$ s. If the interrupt response time is too long, then performance will suffer. If it is too short, then interrupts will occur too frequently.

For Nios II processor systems, read and write thresholds of 8 are an appropriate default.

### Core Overview

The universal asynchronous receiver/transmitter core with Avalon® interface (UART core) implements a method to communicate serial character streams between an embedded system on an Altera® FPGA and an external device. The core implements the RS-232 protocol timing, and provides adjustable baud rate, parity, stop and data bits, and optional RTS/CTS flow control signals. The feature set is configurable, allowing designers to implement just the necessary functionality for a given system.

The core provides a simple register-mapped Avalon Memory-Mapped (Avalon-MM) slave interface that allows Avalon-MM master peripherals (such as a Nios® II processor) to communicate with the core simply by reading and writing control and data registers.

The UART core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [“Functional Description” on page 9-2](#)
- [“Device and Tools Support” on page 9-4](#)
- [“Instantiating the Core in SOPC Builder” on page 9-5](#)
- [“Hardware Simulation Considerations” on page 9-9](#)
- [“Software Programming Model” on page 9-9](#)

## Functional Description

Figure 9–1 shows a block diagram of the UART core.

Figure 9–1. Block Diagram of the UART Core in a Typical System

The core has two user-visible parts:

- The register file, which is accessed via the Avalon-MM slave port
- The RS-232 signals, RXD, TXD, CTS, and RTS

### Avalon-MM Slave Interface and Registers

The UART core provides an Avalon-MM slave interface to the internal register file. The user interface to the UART core consists of six 16-bit registers: `control`, `status`, `rxdata`, `txdata`, `divisor`, and `endofpacket`. A master peripheral, such as a Nios II processor, accesses the registers to control the core and transfer data over the serial connection.

The UART core provides an active-high interrupt request (IRQ) output that can request an interrupt when new data has been received, or when the core is ready to transmit another character. For further details, refer [“Interrupt Behavior” on page 9–20](#).

The Avalon-MM slave port is capable of transfers with flow control. The UART core can be used in conjunction with a direct memory access (DMA) peripheral with Avalon-MM flow control to automate continuous data transfers between, for example, the UART core and memory.

For more information, refer to the *Timer Core* chapter in volume 5 of the *Quartus II Handbook*. For details about the Avalon-MM interface, refer to the *Avalon Memory-Mapped Interface Specification*.

## RS-232 Interface

The UART core implements RS-232 asynchronous transmit and receive logic. The UART core sends and receives serial data via the TXD and RXD ports. The I/O buffers on most Altera FPGA families do not comply with RS-232 voltage levels, and may be damaged if driven directly by signals from an RS-232 connector. To comply with RS-232 voltage signaling specifications, an external level-shifting buffer is required (for example, Maxim MAX3237) between the FPGA I/O pins and the external RS-232 connector.

The UART core uses a logic 0 for mark, and a logic 1 for space. An inverter inside the FPGA can be used to reverse the polarity of any of the RS-232 signals, if necessary.

## Transmitter Logic

The UART transmitter consists of a 7-, 8-, or 9-bit `txdata` holding register and a corresponding 7-, 8-, or 9-bit transmit shift register. Avalon-MM master peripherals write the `txdata` holding register via the Avalon-MM slave port. The transmit shift register is loaded from the `txdata` register automatically when a serial transmit shift operation is not currently in progress. The transmit shift register directly feeds the TXD output. Data is shifted out to TXD least-significant bit (LSB) first.

These two registers provide double buffering. A master peripheral can write a new value into the `txdata` register while the previously written character is being shifted out. The master peripheral can monitor the transmitter's status by reading the `status` register's transmitter ready (`TRDY`), transmitter shift register empty (`tmt`), and transmitter overrun error (`toe`) bits.

The transmitter logic automatically inserts the correct number of start, stop, and parity bits in the serial TXD data stream as required by the RS-232 specification.

## Receiver Logic

The UART receiver consists of a 7-, 8-, or 9-bit receiver-shift register and a corresponding 7-, 8-, or 9-bit `rxdata` holding register. Avalon-MM master peripherals read the `rxdata` holding register via the Avalon-MM slave port. The `rxdata` holding register is loaded from the receiver shift register automatically every time a new character is fully received.

These two registers provide double buffering. The `rxdata` register can hold a previously received character while the subsequent character is being shifted into the receiver shift register.

A master peripheral can monitor the receiver's status by reading the `status` register's read-ready (`rrdy`), receiver-overflow error (`roe`), break detect (`BRK`), parity error (`pe`), and framing error (`fe`) bits. The receiver logic automatically detects the correct number of start, stop, and parity bits in the serial RXD stream as required by the RS-232 specification. The receiver logic checks for four exceptional conditions in the received data (frame error, parity error, receive overrun error, and break), and sets corresponding status register bits (`fe`, `pe`, `roe`, or `BRK`).

## Baud Rate Generation

The UART core's internal baud clock is derived from the Avalon-MM clock input. The internal baud clock is generated by a clock divider. The divisor value can come from one of the following sources:

- A constant value specified at system generation time
- The 16-bit value stored in the `divisor` register

The `divisor` register is an optional hardware feature. If it is disabled at system generation time, the divisor value is fixed, and the baud rate cannot be altered.

The UART core can target all Altera FPGAs.

## Device and Tools Support

## Instantiating the Core in SOPC Builder

Instantiating the UART in hardware creates at least two I/O ports for each UART core: An RXD input, and a TXD output. Optionally, the hardware may include flow control signals, the CTS input and RTS output.

Designers use the MegaWizard® interface for the UART core in SOPC Builder to configure the hardware feature set. The following sections describe the available options.

### Configuration Settings

This section describes the configuration settings.

#### *Baud Rate Options*

The UART core can implement any of the standard baud rates for RS-232 connections. The baud rate can be configured in one of two ways:

- **Fixed rate**—The baud rate is fixed at system generation time and cannot be changed via the Avalon-MM slave port.
- **Variable rate**—The baud rate can vary, based on a clock divisor value held in the `divisor` register. A master peripheral changes the baud rate by writing new values to the `divisor` register.

The baud rate is calculated based on the clock frequency provided by the Avalon-MM interface. Changing the system clock frequency in hardware without re-generating the UART core hardware will result in incorrect signaling.

#### **Baud Rate (bps) Setting**

The **Baud Rate** setting determines the default baud rate after reset. The **Baud Rate** option offers standard preset values (for example, 9600, 57600, 115200 bps), or you can enter any baud rate manually.

The baud rate value is used to calculate an appropriate clock divisor value to implement the desired baud rate. Baud rate and divisor values are related as follows:

$$(1) \quad \text{divisor} = \frac{\text{int}(\text{clock frequency})}{\text{baud rate}} + 0.5$$

$$(2) \quad \text{baud rate} = \frac{\text{clock frequency}}{(\text{divisor} + 1)}$$

### Baud Rate Can Be Changed By Software Setting

When this setting is on, the hardware includes a 16-bit `divisor` register at address offset 4. The `divisor` register is writable, so the baud rate can be changed by writing a new value to this register.

When this setting is off, the UART hardware does not include a `divisor` register. The UART hardware implements a constant (unchangeable) baud divisor, and the value cannot be changed after system generation. In this case, writing to address offset 4 has no effect, and reading from address offset 4 produces an undefined result.

### Data Bits, Stop Bits, Parity

The UART core's parity, data bits and stop bits are configurable. These settings are fixed at system generation time; they cannot be altered via the register file. The following settings are available.

#### Data Bits Setting

The settings shown in [Table 9-1](#) are available.

Setting	Allowed Values	Description
Data Bits	7, 8, 9	This setting determines the widths of the <code>txdata</code> , <code>rxdata</code> , and <code>endofpacket</code> registers.
Stop Bits	1, 2	This setting determines whether the core transmits 1 or 2 stop bits with every character. The core always terminates a receive transaction at the first stop bit, and ignores all subsequent stop bits, regardless of the Stop Bits setting.
Parity	None, Even, Odd	This setting determines whether the UART transmits characters with parity checking, and whether it expects received characters to have parity checking. Refer to " <a href="#">Parity Setting</a> ".

#### Parity Setting

When **Parity** is set to **None**, the transmit logic sends data without including a parity bit, and the receive logic presumes the incoming data does not include a parity bit. When parity is **None**, the status register's parity error (PE) bit is not implemented; it always reads 0.

When **Parity** is set to **Odd** or **Even**, the transmit logic computes and inserts the required parity bit into the outgoing TXD bitstream, and the receive logic checks the parity bit in the incoming RXD bitstream. If the receiver finds data with incorrect parity, the status register's PE is set to 1. When parity is **Even**, the parity bit is 0 if the character has an even number of 1 bits; otherwise the parity bit is 1. Similarly, when parity is **Odd**, the parity bit is 0 if the character has an odd number of 1 bits.

### *Flow Control*

The following flow control option is available.

#### **Include CTS/RTS Pins and Control Register Bits**

When this setting is on, the UART hardware includes:

- `cts_n` (logic negative CTS) input port
- `rts_n` (logic negative RTS) output port
- CTS bit in the `status` register
- DCTS bit in the `status` register
- RTS bit in the `control` register
- IDCTS bit in the `control` register

Based on these hardware facilities, an Avalon-MM master peripheral can detect CTS and transmit RTS flow control signals. The CTS input and RTS output ports are tied directly to bits in the `status` and `control` registers, and have no direct effect on any other part of the core. When using flow control, be sure the terminal program on the host side is also configured for flow control.

When the **Include CTS/RTS pins and control register bits** setting is off, the core does not include the hardware listed above and continuous writes to the UART may lose data. The control/status bits CTS, DCTS, IDCTS, and RTS are not implemented; they always read as 0.

### *Avalon-MM Transfers with Flow Control (DMA)*

The UART core's Avalon-MM interface optionally implements Avalon-MM transfers with flow control. This allows an Avalon-MM master peripheral to write data only when the UART core is ready to accept another character, and to read data only when the core has data available. The UART core can also optionally include the end-of-packet register.

#### **Include End-of-Packet Register**

When this setting is on, the UART core includes:

- A 7-, 8-, or 9-bit `endofpacket` register at address-offset 5. The data width is determined by the **Data Bits** setting.
- `eop` bit in the `status` register
- `ieop` bit in the `control` register
- `endofpacket` signal in the Avalon-MM interface to support data transfers with flow control to/from other master peripherals in the system

End-of-packet (EOP) detection allows the UART core to terminate a data transaction with a Avalon-MM master with flow control. EOP detection can be used with a DMA controller, for example, to implement a UART that automatically writes received characters to memory until a specified character is encountered in the incoming RXD stream. The terminating (EOP) character's value is determined by the `endOfPacket` register.

When the EOP register is disabled, the UART core does not include the resources listed above. Writing to the `endOfPacket` register has no effect, and reading produces an undefined value.

## Simulation Settings

When the UART core's logic is generated, a simulation model is also constructed. The simulation model offers features to simplify and accelerate simulation of systems that use the UART core. Changes to the simulation settings do not affect the behavior of the UART core in hardware; the settings affect only functional simulation.

For examples of how to use the following settings to simulate Nios II systems, refer to *AN 351: Simulating Nios II Embedded Processor Designs*.

### *Simulated RXD-Input Character Stream*

You can enter a character stream that is simulated entering the RXD port upon simulated system reset. The UART core's MegaWizard interface accepts an arbitrary character string, which is later incorporated into the UART simulation model. After reset in reset, the string is input into the RXD port character-by-character as the core is able to accept new data.

### *Prepare Interactive Windows*

At system generation time, the UART core generator can create ModelSim macros that facilitate interaction with the UART model during simulation. The following options are available:

#### **Create ModelSim Alias to Open Streaming Output Window**

A ModelSim macro is created to open a window that displays all output from the TXD port.

#### **Create ModelSim Alias to Open Interactive Stimulus Window**

A ModelSim macro is created to open a window that accepts stimulus for the RXD port. The window sends any characters typed in the window to the RXD port.

### *Simulated Transmitter Baud Rate*

RS-232 transmission rates are often slower than any other process in the system, and it is seldom useful to simulate the functional model at the true baud rate. For example, at 115,200 bps, it typically takes thousands of clock cycles to transfer a single character. The UART simulation model has the ability to run with a constant clock divisor of 2. This allows the simulated UART to transfer bits at half the system clock speed, or roughly one character per 20 clock cycles. You can choose one of the following options for the simulated transmitter baud rate:

- **accelerated (use divisor = 2)**—TXD emits one bit per 2 clock cycles in simulation.
- **actual (use true baud divisor)**—TXD transmits at the actual baud rate, as determined by the `divisor` register.

## Hardware Simulation Considerations

The simulation features were created for easy simulation of Nios, Nios II or Excalibur™ processor systems when using the ModelSim simulator. The documentation for each processor documents the suggested usage of these features. Other usages may be possible, but will require additional user effort to create a custom simulation process.

The simulation model is implemented in the UART core's top-level HDL file; the synthesizable HDL and the simulation HDL are implemented in the same file. The simulation features are implemented using `translate on` and `translate off` synthesis directives that make certain sections of HDL code visible only to the synthesis tool.

Do not edit the simulation directives if you are using Altera's recommended simulation procedures. If you do change the simulation directives for your custom simulation flow, be aware that SOPC Builder overwrites existing files during system generation. Take precaution so that your changes are not overwritten.

For details about simulating the UART core in Nios II processor systems, refer to *AN 351: Simulating Nios II Processor Designs*. For details about simulating the UART core in Nios embedded processor systems, refer to *AN 189: Simulating Nios Embedded Processor Designs*.

## Software Programming Model

The following sections describe the software programming model for the UART core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides hardware abstraction layer (HAL) system library drivers that enable you to access the UART core using the ANSI C standard library functions, such as `printf()` and `getchar()`.

## HAL System Library Support

The Altera-provided driver implements a HAL character-mode device driver that integrates into the HAL system library for Nios II systems. HAL users should access the UART via the familiar HAL API and the ANSI C standard library, rather than accessing the UART registers. `ioctl()` requests are defined that allow HAL users to control the hardware-dependent aspects of the UART.

If your program uses the HAL device driver to access the UART hardware, accessing the device registers directly will interfere with the correct behavior of the driver.

For Nios II processor users, the HAL system library API provides complete access to the UART core's features. Nios II programs treat the UART core as a character mode device, and send and receive data using the ANSI C standard library functions.

The driver supports the CTS/RTS control signals when they are enabled in SOPC Builder. Refer to [“Driver Options: Fast Versus Small Implementations”](#) on page 9–11.

The following code demonstrates the simplest possible usage, printing a message to `stdout` using `printf()`. In this example, the SOPC Builder system contains a UART core, and the HAL system library has been configured to use this device for `stdout`.

---

### **Example 9–1. Example: Printing Characters to a UART Core as `stdout`**

```
#include <stdio.h>
int main ()
{
    printf("Hello world.\n");
    return 0;
}
```

---

The following code demonstrates reading characters from and sending messages to a UART device using the C standard library. In this example, the SOPC Builder system contains a UART core named `uart1` that is not necessarily configured as the `stdout` device. In this case, the program treats the device like any other node in the HAL file system.

---

**Example 9–2. Example: Sending and Receiving Characters**

```
/* A simple program that recognizes the characters 't' and 'v' */
#include <stdio.h>
#include <string.h>
int main ()
{
    char* msg = "Detected the character 't'.\n";
    FILE* fp;
    char prompt = 0;

    fp = fopen ("/dev/uart1", "r+"); //Open file for reading and writing
    if (fp)
    {
        while (prompt != 'v')
        { // Loop until we receive a 'v'.
            prompt = getc(fp); // Get a character from the UART.
            if (prompt == 't')
            { // Print a message if character is 't'.
                fwrite (msg, strlen (msg), 1, fp);
            }
        }

        fprintf(fp, "Closing the UART file.\n");
        fclose (fp);
    }

    return 0;
}
```

---

For more information about the HAL system library, refer to the *Nios II Software Developer's Handbook*.

### *Driver Options: Fast Versus Small Implementations*

To accommodate the requirements of different types of systems, the UART driver provides two variants: a fast version and a small version. The fast version is the default. Both fast and small drivers fully support the C standard library functions and the HAL API.

The fast driver is an interrupt-driven implementation, which allows the processor to perform other tasks when the device is not ready to send or receive data. Because the UART data rate is slow compared to the processor, the fast driver can provide a large performance benefit for systems that could be performing other tasks in the interim.

The small driver is a polled implementation that waits for the UART hardware before sending and receiving each character. There are two ways to enable the small footprint driver:

- Enable the small footprint setting for the HAL system library project. This option affects device drivers for all devices in the system as well.
- Specify the preprocessor option `-DALTERA_AVALON_UART_SMALL`. You can use this option if you want the small, polled implementation of the UART driver, but do not want to affect the drivers for other devices.

Refer to the help system in the Nios II IDE for details about how to set HAL properties and preprocessor options.

If the CTS/RTS flow control signals are enabled in hardware, the fast driver automatically uses them. The small driver always ignores them.

### *ioctl() Operations*

The UART driver supports the `ioctl()` function to allow HAL-based programs to request device-specific operations. [Table 9-2](#) defines operation requests that the UART driver supports.

<b>Table 9-2. UART ioctl() Operations</b>	
<b>Request</b>	<b>Meaning</b>
TIOCEXCL	Locks the device for exclusive access. Further calls to <code>open()</code> for this device will fail until either this file descriptor is closed, or the lock is released using the <code>TIOCNXCL</code> <code>ioctl</code> request. For this request to succeed there can be no other existing file descriptors for this device. The <code>ioctl</code> "arg" parameter is ignored.
TIOCNXCL	Releases a previous exclusive access lock. The <code>ioctl</code> "arg" parameter is ignored.

Additional operation requests are also optionally available for the fast driver only, as shown in Table 9–3. To enable these operations in your program, you must set the preprocessor option `-DALTERA_AVALON_UART_USE_IOCTL`.

**Table 9–3. Optional UART ioctl() Operations for the Fast Driver Only**

Request	Meaning
TIOCMGET	Returns the current configuration of the device by filling in the contents of the input termios (1) structure. A pointer to this structure is supplied as the value of the <code>ioctl</code> “opt” parameter.
TIOCMSET	Sets the configuration of the device according to the values contained in the input termios structure (1). A pointer to this structure is supplied as the value of the <code>ioctl</code> “arg” parameter.

**Note to Table 9–3:**

- (1) The termios structure is defined by the Newlib C standard library. You can find the definition in the file `<Nios II EDS install path>/components/altera_hal/HAL/inc/sys/termios.h`.

Refer to the *Nios II Software Developer’s Handbook* for details about the `ioctl()` function.

### Limitations

The HAL driver for the UART core does not support the `endofpacket` register. Refer to “[Register Map](#)” for details.

### Software Files

The UART core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- `altera_avalon_uart_regs.h`—This file defines the core’s register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used only by device driver functions.
- `altera_avalon_uart.h`, `altera_avalon_uart.c`—These files implement the UART core device driver for the HAL system library.

### Legacy SDK Routines

The UART core is also supported by the legacy SDK routines for the first-generation Nios processor.

For details about these routines, refer to the UART documentation that accompanied the first-generation Nios processor. For details about upgrading programs based on the legacy SDK to the HAL system library API, refer to *AN 350: Upgrading Nios Processor Systems to the Nios II Processor*.

## Register Map

Programmers using the HAL API or the legacy SDK for the first-generation Nios processor never access the UART core directly via its registers. In general, the register map is only useful to programmers writing a device driver for the core.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver and the HAL driver is active for the same device, your driver will conflict and fail to operate.

Table 9–4 shows the register map for the UART core. Device drivers control and communicate with the core through the memory-mapped registers.

Offset	Register Name	R/W	Description/Register Bits													
			15 . . . 13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	rxdata	RO	(1)					(2)	(2)	Receive Data						
1	txdata	WO	(1)					(2)	(2)	Transmit Data						
2	status (3)	RW	(1)	eop	cts	dcts	(1)	e	rrdy	trdy	tmt	toe	roe	brk	fe	pe
3	control	RW	(1)	ieop	rts	idcts	trbk	ie	irrdy	itrdy	itmt	itoe	iroe	ibrk	ife	ipe
4	divisor (4)	RW	Baud Rate Divisor													
5	endof-packet (4)	RW	(1)					(2)	(2)	End-of-Packet Value						

### Notes to Table 9–4:

- (1) These bits are reserved. Reading returns an undefined value. Write zero.
- (2) These bits may or may not exist, depending on the **Data Width** hardware option. If they do not exist, they read zero, and writing has no effect.
- (3) Writing zero to the status register clears the dcts, e, toe, roe, brk, fe, and PE bits.
- (4) This register may or may not exist, depending on hardware configuration options. If it does not exist, reading returns an undefined value and writing has no effect.

Some registers and bits are optional. These registers and bits exist in hardware only if it was enabled at system generation time. Optional registers and bits are noted in the following sections.

### *rxdata Register*

The `rxdata` register holds data received via the RXD input. When a new character is fully received via the RXD input, it is transferred into the `rxdata` register, and the `status` register's `rrdy` bit is set to 1. The `status` register's `rrdy` bit is set to 0 when the `rxdata` register is read. If a character is transferred into the `rxdata` register while the `rrdy` bit is already set (in other words, the previous character was not retrieved), a receiver-overflow error occurs and the `status` register's `roe` bit is set to 1. New characters are always transferred into the `rxdata` register, regardless of whether the previous character was read. Writing data to the `rxdata` register has no effect.

### *txdata Register*

Avalon-MM master peripherals write characters to be transmitted into the `txdata` register. Characters should not be written to `txdata` until the transmitter is ready for a new character, as indicated by the `TRDY` bit in the `status` register. The `TRDY` bit is set to 0 when a character is written into the `txdata` register. The `TRDY` bit is set to 1 when the character is transferred from the `txdata` register into the transmitter shift register. If a character is written to the `txdata` register when `TRDY` is 0, the result is undefined. Reading the `txdata` register returns an undefined value.

For example, assume the transmitter logic is idle and an Avalon-MM master peripheral writes a first character into the `txdata` register. The `TRDY` bit is set to 0, then set to 1 when the character is transferred into the transmitter shift register. The master can then write a second character into the `txdata` register, and the `TRDY` bit is set to 0 again. However, this time the shift register is still busy shifting out the first character to the TXD output. The `TRDY` bit is not set to 1 until the first character is fully shifted out and the second character is automatically transferred into the transmitter shift register.

### *status Register*

The `status` register consists of individual bits that indicate particular conditions inside the UART core. Each status bit is associated with a corresponding interrupt-enable bit in the `control` register. The `status` register can be read at any time. Reading does not change the value of any of the bits. Writing zero to the `status` register clears the `DCTS`, `E`, `TOE`, `ROE`, `BRK`, `FE`, and `PE` bits.

The status register bits are shown in [Table 9-5](#).

Bit	Bit Name	Read/ Write/ Clear	Description
0 (1)	PE	RC	<p>Parity error. A parity error occurs when the received parity bit has an unexpected (incorrect) logic level. The PE bit is set to 1 when the core receives a character with an incorrect parity bit. The PE bit stays set to 1 until it is explicitly cleared by a write to the status register. When the PE bit is set, reading from the <code>rxdata</code> register produces an undefined value.</p> <p>If the <b>Parity</b> hardware option is not enabled, no parity checking is performed and the PE bit always reads 0. Refer to <a href="#">“Data Bits, Stop Bits, Parity” on page 9-6</a>.</p>
1	FE	RC	<p>Framing error. A framing error occurs when the receiver fails to detect a correct stop bit. The FE bit is set to 1 when the core receives a character with an incorrect stop bit. The FE bit stays set to 1 until it is explicitly cleared by a write to the status register. When the FE bit is set, reading from the <code>rxdata</code> register produces an undefined value.</p>
2	BRK	RC	<p>Break detect. The receiver logic detects a break when the <code>RXD</code> pin is held low (logic 0) continuously for longer than a full-character time (data bits, plus start, stop, and parity bits). When a break is detected, the BRK bit is set to 1. The BRK bit stays set to 1 until it is explicitly cleared by a write to the status register.</p>
3	ROE	RC	<p>Receive overrun error. A receive-overrun error occurs when a newly received character is transferred into the <code>rxdata</code> holding register before the previous character is read (in other words, while the <code>RRDY</code> bit is 1). In this case, the ROE bit is set to 1, and the previous contents of <code>rxdata</code> are overwritten with the new character. The ROE bit stays set to 1 until it is explicitly cleared by a write to the status register.</p>
4	TOE	RC	<p>Transmit overrun error. A transmit-overrun error occurs when a new character is written to the <code>txdata</code> holding register before the previous character is transferred into the shift register (in other words, while the <code>TRDY</code> bit is 0). In this case the TOE bit is set to 1. The TOE bit stays set to 1 until it is explicitly cleared by a write to the status register.</p>
5	TMT	R	<p>Transmit empty. The TMT bit indicates the transmitter shift register's current state. When the shift register is in the process of shifting a character out the <code>TXD</code> pin, TMT is set to 0. When the shift register is idle (in other words, a character is not being transmitted) the TMT bit is 1. An Avalon-MM master peripheral can determine if a transmission is completed (and received at the other end of a serial link) by checking the TMT bit.</p>

**Table 9–5. status Register Bits (Part 2 of 3)**

Bit	Bit Name	Read/ Write/ Clear	Description
6	TRDY	R	Transmit ready. The TRDY bit indicates the <code>txdata</code> holding register's current state. When the <code>txdata</code> register is empty, it is ready for a new character, and TRDY is 1. When the <code>txdata</code> register is full, TRDY is 0. An Avalon-MM master peripheral must wait for TRDY to be 1 before writing new data to <code>txdata</code> .
7	RRDY	R	Receive character ready. The RRDY bit indicates the <code>rxdata</code> holding register's current state. When the <code>rxdata</code> register is empty, it is not ready to be read and <code>rrdy</code> is 0. When a newly received value is transferred into the <code>rxdata</code> register, RRDY is set to 1. Reading the <code>rxdata</code> register clears the RRDY bit to 0. An Avalon-MM master peripheral must wait for RRDY to equal 1 before reading the <code>rxdata</code> register.
8	E	RC	Exception. The E bit indicates that an exception condition occurred. The E bit is a logical-OR of the TOE, ROE, BRK, FE, and PE bits. The <code>e</code> bit and its corresponding interrupt-enable bit (IE) bit in the <code>control</code> register provide a convenient method to enable/disable IRQs for all error conditions.  The E bit is set to 0 by a write operation to the status register.
10 (1)	DCTS	RC	Change in clear to send (CTS) signal. The DCTS bit is set to 1 whenever a logic-level transition is detected on the <code>CTS_N</code> input port (sampled synchronously to the Avalon-MM clock). This bit is set by both falling and rising transitions on <code>CTS_N</code> . The DCTS bit stays set to 1 until it is explicitly cleared by a write to the <code>status</code> register.  If the <b>Flow Control</b> hardware option is not enabled, the DCTS bit always reads 0. Refer to <a href="#">“Flow Control” on page 9–7</a> .
11 (1)	CTS	R	Clear-to-send (CTS) signal. The CTS bit reflects the <code>CTS_N</code> input's instantaneous state (sampled synchronously to the Avalon-MM clock). Because the <code>CTS_N</code> input is logic negative, the CTS bit is 1 when a 0 logic-level is applied to the <code>CTS_N</code> input.  The <code>CTS_N</code> input has no effect on the transmit or receive processes. The only visible effect of the <code>CTS_N</code> input is the state of the CTS and DCTS bits, and an IRQ that can be generated when the control register's <code>idcts</code> bit is enabled.  If the <b>Flow Control</b> hardware option is not enabled, the CTS bit always reads 0. Refer to <a href="#">“Flow Control” on page 9–7</a> .

**Table 9–5. status Register Bits (Part 3 of 3)**

Bit	Bit Name	Read/ Write/ Clear	Description
12 (1)	EOP	R	<p>End of packet encountered. The EOP bit is set to 1 by one of the following events:</p> <ul style="list-style-type: none"> <li>• An EOP character is written to <code>txdata</code></li> <li>• An EOP character is read from <code>rxdata</code></li> </ul> <p>The EOP character is determined by the contents of the <code>endofpacket</code> register. The EOP bit stays set to 1 until it is explicitly cleared by a write to the <code>status</code> register.</p> <p>If the <b>Include End-of-Packet Register</b> hardware option is not enabled, the EOP bit always reads 0. Refer to “<a href="#">Avalon-MM Transfers with Flow Control (DMA)</a>” on page 9–7.</p>

*Note to Table 9–5:*

- (1) This bit is optional and may not exist in hardware.

### *control Register*

The `control` register consists of individual bits, each controlling an aspect of the UART core’s operation. The value in the `control` register can be read at any time.

Each bit in the `control` register enables an IRQ for a corresponding bit in the `status` register. When both a status bit and its corresponding interrupt-enable bit are 1, the core generates an IRQ. For example, the PE bit is bit 0 of the `status` register, and the `ipe` bit is bit 0 of the `control` register. An interrupt request is generated when both PE and `ipe` equal 1.

The control register bits are shown in [Table 9–6](#).

**Table 9–6. control Register Bits (Part 1 of 2)**

Bit	Bit Name	Read/ Write	Description
0	IPE	RW	Enable interrupt for a parity error.
1	IFE	RW	Enable interrupt for a framing error.
2	IBRK	RW	Enable interrupt for a break detect.
3	IROE	RW	Enable interrupt for a receiver overrun error.
4	ITOE	RW	Enable interrupt for a transmitter overrun error.
5	ITMT	RW	Enable interrupt for a transmitter shift register empty.

**Table 9–6. control Register Bits (Part 2 of 2)**

Bit	Bit Name	Read/Write	Description
6	ITRDY	RW	Enable interrupt for a transmission ready.
7	IRRDY	RW	Enable interrupt for a read ready.
8	IE	RW	Enable interrupt for an exception.
9	TRBK	RW	Transmit break. The TRBK bit allows an Avalon-MM master peripheral to transmit a break character over the TXD output. The TXD signal is forced to 0 when the TRBK bit is set to 1. The TRBK bit overrides any logic level that the transmitter logic would otherwise drive on the TXD output. The TRBK bit interferes with any transmission in process. The Avalon-MM master peripheral must set the TRBK bit back to 0 after an appropriate break period elapses.
10	IDCTS	RW	Enable interrupt for a change in CTS signal.
11 (1)	RTS	RW	Request to send (RTS) signal. The RTS bit directly feeds the RTS_N output. An Avalon-MM master peripheral can write the RTS bit at any time. The value of the RTS bit only affects the RTS_N output; it has no effect on the transmitter or receiver logic. Because the RTS_N output is logic negative, when the RTS bit is 1, a low logic-level (0) is driven on the RTS_N output.  If the <b>Flow Control</b> hardware option is not enabled, the RTS bit always reads 0, and writing has no effect. Refer to <a href="#">“Flow Control” on page 9–7</a> .
12	IEOP	RW	Enable interrupt for end-of-packet condition.

**Note to Table 9–6:**

- (1) This bit is optional and may not exist in hardware.

### *divisor Register (Optional)*

The value in the `divisor` register is used to generate the baud rate clock. The effective baud rate is determined by the formula shown in [Equation 3](#):

$$(3) \quad \text{baud rate} = \frac{\text{clock frequency}}{(\text{divisor} + 1)}$$

The `divisor` register is an optional hardware feature. If the **Baud Rate Can Be Changed By Software** hardware option is not enabled, then the `divisor` register does not exist. In this case, writing `divisor` has no effect, and reading `divisor` returns an undefined value. For more information, refer to [“Baud Rate Options” on page 9–5](#).

### *endofpacket Register (Optional)*

The value in the `endofpacket` register determines the end-of-packet character for variable-length DMA transactions. After reset, the default value is zero, which is the ASCII null character (`\0`). For more information, refer to [Table 9–5 on page 9–16](#) for the description for the `eop` bit.

The `endofpacket` register is an optional hardware feature. If the **Include end-of-packet register** hardware option is not enabled, then the `endofpacket` register does not exist. In this case, writing `endofpacket` has no effect, and reading returns an undefined value.

## **Interrupt Behavior**

The UART core outputs a single IRQ signal to the Avalon-MM interface, which can connect to any master peripheral in the system, such as a Nios II processor. The master peripheral must read the `status` register to determine the cause of the interrupt.

Every interrupt condition has an associated bit in the `status` register and an interrupt-enable bit in the `control` register. When any of the interrupt conditions occur, the associated `status` bit is set to 1 and remains set until it is explicitly acknowledged. The IRQ output is asserted when any of the status bits are set while the corresponding interrupt-enable bit is 1. A master peripheral can acknowledge the IRQ by clearing the status register.

At reset, all interrupt-enable bits are set to 0; therefore, the core cannot assert an IRQ until a master peripheral sets one or more of the interrupt-enable bits to 1.

All possible interrupt conditions are listed with their associated status and control (interrupt-enable) bits in [Table 6–5 on page 6–16](#) and [Table 6–6 on page 6–18](#). Details of each interrupt condition are provided in the status bit descriptions.

March 2007 v7.0.0	No change from previous release.	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>Updated Avalon terminology because of changes to Avalon technologies. Changed old “Avalon interface” terms to “Avalon Memory-Mapped interface.”</li> <li>Corrected definition of even and odd parity in section “<i>Data Bits, Stop Bits, Parity</i>” on page 8–6.</li> </ul>	For the 6.1 release, Altera released the Avalon Streaming interface, which necessitated some re-phrasing of existing Avalon terminology. Other changes to the document serve only to clarify existing behavior.
May 2006 v6.0.0	No change from previous release.	—
December 2005 v5.1.1	Changed Avalon “streaming” terminology to “flow control” based on a change to the <i>Avalon Interface Specification</i> .	—
October 2005 v5.1.0	No change from previous release.	—
May 2005 v5.0.0	No change from previous release. Previously in the Nios II Processor Reference Handbook.	—
September 2004 v1.1	Updates for Nios II 1.01 release.	—
May 2004 v1.0	Initial release.	—

## Core Overview

SPI is an industry-standard serial protocol commonly used in embedded systems to connect microprocessors to a variety of off-chip sensor, conversion, memory, and control devices. The SPI core with Avalon® interface implements the SPI protocol and provides an Avalon Memory-Mapped (Avalon-MM) interface on the back end.

The SPI core can implement either the master or slave protocol. When configured as a master, the SPI core can control up to 16 independent SPI slaves. The width of the receive and transmit registers are configurable between 1 and 16 bits. Longer transfer lengths (for example, 24-bit transfers) can be supported with software routines. The SPI core provides an interrupt output that can flag an interrupt whenever a transfer completes.

The SPI core is SOPC Builder ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [“Functional Description”](#)
- [“Instantiating the SPI Core in SOPC Builder”](#) on page 10–7
- [“Device and Tools Support”](#) on page 10–10
- [“Software Programming Model”](#) on page 10–10

## Functional Description

The SPI core communicates using two data lines, a control line, and a synchronization clock:

- **Master Out Slave In** (*mosi*)—Output data from the master to the inputs of the slaves
- **Master In Slave Out** (*miso*)—Output data from a slave to the input of the master
- **Serial Clock** (*sclk*)—Clock driven by the master to slaves, used to synchronize the data bits
- **Slave Select** (*ss\_n*)— Select signal (active low) driven by the master to individual slaves, used to select the target slave

The SPI core has the following user-visible features:

- A memory-mapped register space comprised of five registers: *rxdata*, *txdata*, *status*, *control*, and *slaveselect*
- Four SPI interface ports: *sclk*, *ss\_n*, *mosi*, and *miso*

The registers provide an interface to the SPI core and are visible via the Avalon-MM slave port. The `sclk`, `ss_n`, `mosi`, and `miso` ports provide the hardware interface to other SPI devices. The behavior of `sclk`, `ss_n`, `mosi`, and `miso` depends on whether the SPI core is configured as a master or slave.

Figure 10–1 shows a block diagram of the SPI core in master mode.

**Figure 10–1. SPI Core Block Diagram**

The SPI core logic is synchronous to the clock input provided by the Avalon-MM interface. When configured as a master, the core divides the Avalon-MM clock to generate the SCLK output. When configured as a slave, the core's receive logic is synchronized to SCLK input. The core's Avalon-MM interface is capable of Avalon-MM transfers with flow control. The SPI core can be used in conjunction with a DMA controller with flow control to automate continuous data transfers between, for example, the SPI core and memory. See the *Timer Core* chapter for details.

### Example Configurations

Two possible configurations are shown below. In Figure 10–2, the SPI core provides a slave interface to an off-chip SPI master.

**Figure 10–2. SPI Core Configured as a Slave**

In [Figure 10–3](#) the SPI core provides a master interface driving multiple off-chip slave devices. Each slave device in [Figure 10–3](#) must tristate its `miso` output whenever its select signal is not asserted.

**Figure 10–3. SPI Core Configured as a Master**

The `ss_n` signal is active-low. However, any signal can be inverted inside the FPGA, allowing the slave-select signals to be either active high or active low.

## Transmitter Logic

The SPI core transmitter logic consists of a transmit holding register (`txdata`) and transmit shift register, each  $n$  bits wide. The register width  $n$  is specified at system generation time, and can be any integer value from 1 to 16. After a master peripheral writes a value to the `txdata` register, the value is copied to the shift register and then transmitted when the next operation starts.

The shift register and the `txdata` register provide double buffering during data transmission. A new value can be written into the `txdata` register while the previous data is being shifted out of the shift register. The transmitter logic automatically transfers the `txdata` register to the shift register whenever a serial shift operation is not currently in process.

In master mode, the transmit shift register directly feeds the `mosi` output. In slave mode, the transmit shift register directly feeds the `misso` output. Data shifts out least-significant bit (LSB) first or most-significant bit (MSB) first, depending on the configuration of the SPI core.

## Receiver Logic

The SPI core receive logic consists of a receive holding register (`rxdata`) and receive shift register, each  $n$  bits wide. The register width  $n$  is specified at system generation time, and can be any integer value from 1 to 16. A master peripheral reads received data from the `rxdata` register after the shift register has captured a full  $n$ -bit value of data.

The shift register and the `rxdata` register provide double buffering during data receiving. The `rxdata` register can hold a previously received data value while subsequent new data is shifting into the shift register. The receiver logic automatically transfers the shift register content to the `rxdata` register when a serial shift operation completes.

In master mode, the shift register is fed directly by the `misso` input. In slave mode, the shift register is fed directly by the `mosi` input. The receiver logic expects input data to arrive least-significant bit (LSB) first or most-significant bit (MSB) first, depending on the configuration of the SPI core.

## Master and Slave Modes

At system generation time, the designer configures the SPI core in either master mode or slave mode. The mode cannot be switched at runtime.

### Master Mode Operation

In master mode, the SPI ports behave as shown in [Table 10-1](#).

<b>Name</b>	<b>Direction</b>	<b>Description</b>
<code>mosi</code>	output	Data output to slave(s)
<code>miso</code>	input	Data input from slave(s)
<code>sclk</code>	output	Synchronization clock to all slaves
<code>ss_nM</code>	output	Slave select signal to slave <i>M</i> , where <i>M</i> is a number between 0 and 15.

Only an SPI master can initiate an operation between master and slave. In master mode, an intelligent host (for example, a microprocessor) configures the SPI core using the `control` and `slaveselct` registers, and then writes data to the `txdata` buffer to initiate a transaction. A master peripheral can monitor the status of the transaction by reading the `status` register. A master peripheral can enable interrupts to notify the host whenever new data is received (that is, a transfer has completed), or whenever the transmit buffer is ready for new data.

The SPI protocol is full duplex, so every transaction both sends and receives data at the same time. The master transmits a new data bit on the `mosi` output and the slave drives a new data bit on the `miso` input for each active edge of `sclk`. The SPI core divides the Avalon-MM system clock using a clock divider to generate the `sclk` signal.

When the SPI core is configured to interface with multiple slaves, the core has one `ss_n` signal for each slave, up to a maximum of sixteen slaves. During a transfer, the master asserts `ss_n` to each slave specified in the `slaveselct` register. Note that there can be no more than one slave transmitting data during any particular transfer, or else there will be a conflict on the `miso` input. The number of slave devices is specified at system generation time.

### Slave Mode Operation

In slave mode, the SPI ports behave as shown in [Table 10-2](#).

<b>Table 10-2. Slave Mode Port Configurations</b>		
<b>Name</b>	<b>Direction</b>	<b>Description</b>
<code>mosi</code>	input	Data input from the master
<code>miso</code>	output	Data output to the master
<code>sclk</code>	input	Synchronization clock
<code>ss_n</code>	input	Select signal

In slave mode, the SPI core simply waits for the master to initiate transactions. Before a transaction begins, the slave logic is continuously polling the `ss_n` input. When the master asserts `ss_n` (drives it low), the slave logic immediately begins sending the transmit shift register contents to the `miso` output. The slave logic also captures data on the `mosi` input, and fills the receive shift register simultaneously. Thus, a read and write transaction are carried out simultaneously.

An intelligent host (for example, a microprocessor) writes data to the `txdata` registers, so that it will be transmitted the next time the master initiates an operation. A master peripheral reads received data from the `rxdata` register. A master peripheral can enable interrupts to notify the host whenever new data is received, or whenever the transmit buffer is ready for new data.

### Multi-Slave Environments

When `ss_n` is not asserted, typical SPI cores set their `miso` output pins to high impedance. The Altera<sup>®</sup>-provided SPI slave core drives an undefined high or low value on its `miso` output when not selected. Special consideration is necessary to avoid signal contention on the `miso` output, if the SPI core in slave mode will be connected to an off-chip SPI master device with multiple slaves. In this case, the `ss_n` input should be used to control a tristate buffer on the `miso` signal. [Figure 10-4](#) shows an example of the SPI core in slave mode in an environment with two slaves.

**Figure 10–4. SPI Core in a Multi-Slave Environment**

## Avalon-MM Interface

The SPI core's Avalon-MM interface consists of a single Avalon-MM slave port. In addition to fundamental slave read and write transfers, the SPI core supports Avalon-MM read and write transfers with flow control.

## Instantiating the SPI Core in SOPC Builder

Designers use the MegaWizard® interface for the SPI core in SOPC Builder to configure the hardware feature set. The following sections describe the available options.

### Master/Slave Settings

The designer can select either master mode or slave mode to determine the role of the SPI core. When master mode is selected, the following options are available:

- "Generate Select Signals"
- "SPI Clock (sclk) Rate" on page 10–8
- "Specify Delay" on page 10–8

#### Generate Select Signals

This setting specifies how many slaves the SPI master will connect to. The acceptable range is 1 to 16. The SPI master core presents a unique `ss_n` signal for each slave.

### SPI Clock (sclk) Rate

This setting determines the rate of the `sclk` signal that synchronizes data between master and slaves. The target clock rate can be specified in units of Hz, kHz or MHz. The SPI master core uses the Avalon-MM system clock and a clock divisor to generate `sclk`.

The actual frequency of `sclk` may not exactly match the desired target clock rate. The achievable clock values are:

$$\langle \text{Avalon-MM system clock frequency} \rangle / [2, 4, 6, 8, \dots]$$

The actual frequency achieved will not be greater than the specified target value. For example, if the system clock frequency is 50 MHz and the target value is 25 MHz, then the clock divisor is 2 and the actual `sclk` frequency achieves exactly 25 MHz. However, if the target frequency is 24 MHz, then the clock divisor is 4 and the actual `sclk` frequency becomes 12.5 MHz.

### Specify Delay

Turning on this option causes the SPI master to add a time delay between asserting the `ss_n` signal and shifting the first bit of data. This delay is required by certain SPI slave devices. If the delay option is on, the designer must also specify the delay time in units of ns, us or ms. An example is shown in [Figure 10–5](#).

**Figure 10–5. Time Delay Between Asserting `ss_n` and Toggling `sclk`**

The delay generation logic uses a granularity of half the period of `sclk`. The actual delay achieved is the desired target delay rounded up to the nearest multiple of half the `sclk` period, as shown in the following equations:

$$(1) \quad p = \frac{1}{2}(\text{period of sclk})$$

$$(2) \quad \text{actual delay} = \text{ceiling}\left(\frac{\langle \text{desired delay} \rangle}{p}\right) \times p$$

## Data Register Settings

The data register settings affect the size and behavior of the data registers in the SPI core. There are two data register settings:

- *Width*—This setting specifies the width of `rxdata`, `txdata`, and the receive and transmit shift registers. Acceptable values are from 1 to 16.
- *Shift direction*—This setting determines the direction that data shifts (MSB first or LSB first) into and out of the shift registers.

## Timing Settings

The timing settings affect the timing relationship between the `ss_n`, `sclk`, `mosi` and `miso` signals. In this discussion the `mosi` and `miso` signals are referred to generically as “data”. There are two timing settings:

- *Clock polarity*—This setting can be 0 or 1. When clock polarity is set to 0, the idle state for `sclk` is low. When clock polarity is set to 1, the idle state for `sclk` is high.
- *Clock phase*—This setting can be 0 or 1. When clock phase is 0, data is latched on the leading edge of `sclk`, and data changes on trailing edge. When clock phase is 1, data is latched on the trailing edge of `sclk`, and data changes on the leading edge.

Figures 10–6 through 10–9 demonstrate the behavior of signals in all possible cases of clock polarity and clock phase.

**Figure 10–6. Clock Polarity = 0, Clock Phase = 0**

**Figure 10–7. Clock Polarity = 0, Clock Phase = 1**

**Figure 10–8. Clock Polarity = 1, Clock Phase = 0**

**Figure 10–9. Clock Polarity = 1, Clock Phase = 1**

## Device and Tools Support

The SPI core can target all Altera FPGAs.

## Software Programming Model

The following sections describe the software programming model for the SPI core, including the register map and software constructs used to access the hardware. For Nios<sup>®</sup> II processor users, Altera provides the HAL system library header file that defines the SPI core registers. The SPI core does not match the generic device model categories supported by the HAL, so it cannot be accessed via the HAL API or the ANSI C standard library. Altera provides a routine to access the SPI hardware that is specific to the SPI core.

### Hardware Access Routines

Altera provides one access routine, `alt_avalon_spi_command()`, that provides general-purpose access to an SPI core configured as a master.

## alt\_avalon\_spi\_command()

**Prototype:**

```
int alt_avalon_spi_command(alt_u32 base, alt_u32 slave,
                           alt_u32 write_length,
                           const alt_u8* wdata,
                           alt_u32 read_length,
                           alt_u8* read_data,
                           alt_u32 flags)
```

**Thread-safe:** No.

**Available from ISR:** No.

**Include:** <altera\_avalon\_spi.h>

**Description:** alt\_avalon\_spi\_command() is used to perform a control sequence on the SPI bus. This routine is designed for SPI masters of 8-bit data width or less. Currently, it does not support SPI hardware with data-width greater than 8 bits. A single call to this function writes a data buffer of arbitrary length out the MOSI port, and then reads back an arbitrary amount of data from the MISO port. The function performs the following actions:

- (1) Asserts the slave select output for the specified slave. The first slave select output is numbered 0, the next is 1, etc.
- (2) Transmits write\_length bytes of data from wdata through the SPI interface, discarding the incoming data on MISO.
- (3) Reads read\_length bytes of data, storing the data into the buffer pointed to by read\_data. MOSI is set to zero during the read transaction.
- (4) De-asserts the slave select output, unless the flags field contains the value ALT\_AVALON\_SPI\_COMMAND\_MERGE. If you want to transmit from scattered buffers then you can call the function multiple times, specifying the merge flag on all the accesses except the last.

This function is not thread safe. If you want to access the SPI bus from more than one thread, then you should use a semaphore or mutex to ensure that only one thread is executing within this function at any time.

**Returns:** The number of bytes stored in the read\_data buffer.

## Software Files

The SPI core is accompanied by the following software files. These files provide a low-level interface to the hardware.

- **altera\_avalon\_spi.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_spi.c**—This file implements low-level routines to access the hardware.

## Legacy SDK Routines

The SPI core is also supported by the legacy SDK routines for the first-generation Nios processor. For details about these routines, refer to the SPI documentation that accompanied the first-generation Nios processor.

For details about upgrading programs based on the legacy SDK to the HAL system library API, refer to *AN 350: Upgrading Nios Processor Systems to the Nios II Processor*.

## Register Map

An Avalon-MM master peripheral controls and communicates with the SPI core via the six 16-bit registers, shown in [Table 10-3](#). The table assumes an  $n$ -bit data width for `rxdata` and `txdata`.

Internal Address	Register Name	15...11	10	9	8	7	6	5	4	3	2	1	0
0	<code>rxdata</code> (1)	RXDATA (n-1..0)											
1	<code>txdata</code> (1)	TXDATA (n-1..0)											
2	<code>status</code> (2)				E	RRDY	TRDY	TMT	TOE	ROE			
3	<code>control</code>		sso (3)		IE	IRRDY	ITRDY		ITOE	IROE			
4	Reserved												
5	<code>slaveselect</code> (3)	Slave Select Mask											

### Notes to [Table 10-3](#):

- (1) Bits 15 to  $n$  are undefined when  $n$  is less than 16.
- (2) A write operation to the `status` register clears the `roe`, `toe` and `e` bits.
- (3) Present only in master mode.

Reading undefined bits returns an undefined value. Writing to undefined bits has no effect.

### *rxdata Register*

A master peripheral reads received data from the `rxdata` register. When the receive shift register receives a full  $n$  bits of data, the `status` register's `rrdy` bit is set to 1 and the data is transferred into the `rxdata` register. Reading the `rxdata` register clears the `rrdy` bit. Writing to the `rxdata` register has no effect.

New data is always transferred into the `rxdata` register, whether or not the previous data was retrieved. If `rrdy` is 1 when data is transferred into the `rxdata` register (that is, the previous data was not retrieved), a receive-overflow error occurs and the `status` register's `roe` bit is set to 1. In this case, the contents of `rxdata` are undefined.

### *txdata Register*

A master peripheral writes data to be transmitted into the `txdata` register. When the `status` register's `trdy` bit is 1, it indicates that the `txdata` register is ready for new data. The `trdy` bit is set to 0 whenever the `txdata` register is written. The `trdy` bit is set to 1 after data is transferred from the `txdata` register into the transmitter shift register, which readies the `txdata` holding register to receive new data.

A master peripheral should not write to the `txdata` register until the transmitter is ready for new data. If `trdy` is 0 and a master peripheral writes new data to the `txdata` register, a transmit-overflow error occurs and the `status` register's `toe` bit is set to 1. In this case, the new data is ignored, and the content of `txdata` remains unchanged.

As an example, assume that the SPI core is idle (that is, the `txdata` register and transmitter shift register are empty), when a CPU writes a data value into the `txdata` holding register. The `trdy` bit is set to 0 momentarily, but after the data in `txdata` is transferred into the transmitter shift register, `trdy` returns to 1. The CPU writes a second data value into the `txdata` register, and again the `trdy` bit is set to 0. This time the shift register is still busy transferring the original data value, so the `trdy` bit remains at 0 until the shift operation completes. When the operation completes, the second data value is transferred into the transmitter shift register and the `trdy` bit is again set to 1.

### *status Register*

The `status` register consists of bits that indicate status conditions in the SPI core. Each bit is associated with a corresponding interrupt-enable bit in the `control` register, as discussed in [“control Register” on page 10–14](#).

A master peripheral can read `status` at any time without changing the value of any bits. Writing `status` does clear the `roe`, `toe` and `e` bits. [Table 10-4](#) describes the individual bits of the `status` register.

#	Name	Description
3	ROE	<b>Receive-overflow error</b> The ROE bit is set to 1 if new data is received while the <code>rxdata</code> register is full (that is, while the RRDY bit is 1). In this case, the new data overwrites the old. Writing to the <code>status</code> register clears the ROE bit to 0.
4	TOE	<b>Transmitter-overflow error</b> The TOE bit is set to 1 if new data is written to the <code>txdata</code> register while it is still full (that is, while the TRDY bit is 0). In this case, the new data is ignored. Writing to the <code>status</code> register clears the TOE bit to 0.
5	TMT	<b>Transmitter shift-register empty</b> The TMT bit is set to 0 when a transaction is in progress and set to 1 when the shift register is empty.
6	TRDY	<b>Transmitter ready</b> The TRDY bit is set to 1 when the <code>txdata</code> register is empty.
7	RRDY	<b>Receiver ready</b> The RRDY bit is set to 1 when the <code>rxdata</code> register is full.
8	E	<b>Error</b> The E bit is the logical OR of the TOE and ROE bits. This is a convenience for the programmer to detect error conditions. Writing to the <code>status</code> register clears the E bit to 0.

### *control Register*

The control register consists of data bits to control the SPI core's operation. A master peripheral can read `control` at any time without changing the value of any bits.

Most bits (`IROE`, `ITOE`, `ITRDY`, `IRRDY`, and `IE`) in the `control` register control interrupts for status conditions represented in the `status` register. For example, bit 1 of `status` is ROE (receiver-overflow error), and bit 1 of `control` is `IROE`, which enables interrupts for the ROE condition. The SPI core asserts an interrupt request when the corresponding bits in `status` and `control` are both 1.

The control register bits are shown in [Table 10–5](#).

#	Name	Description
3	IROE	Setting IROE to 1 enables interrupts for receive-overflow errors.
4	ITOE	Setting ITOE to 1 enables interrupts for transmitter-overflow errors.
6	ITRDY	Setting ITRDY to 1 enables interrupts for the transmitter ready condition.
7	IRRDY	Setting IRRDY to 1 enables interrupts for the receiver ready condition.
8	IE	Setting IE to 1 enables interrupts for any error condition.
10	SSO	Setting SSO to 1 forces the SPI core to drive its <code>ss_n</code> outputs, regardless of whether a serial shift operation is in progress or not. The <code>slaveselct</code> register controls which <code>ss_n</code> outputs are asserted. <code>SSO</code> can be used to transmit or receive data of arbitrary size (in other words, greater than 16 bits).

After reset, all bits of the control register are set to 0. All interrupts are disabled and no `ss_n` signals are asserted after reset.

#### *slaveselct Register*

The `slaveselct` register is a bit mask for the `ss_n` signals driven by an SPI master. During a serial shift operation, the SPI master selects only the slave device(s) specified in the `slaveselct` register.

The `slaveselct` register is only present when the SPI core is configured in master mode. There is one bit in `slaveselct` for each `ss_n` output, as specified by the designer at system generation time. For example, to enable communication with slave device 3, set bit 3 of `slaveselct` to 1.

A master peripheral can set multiple bits of `slaveselct` simultaneously, causing the SPI master to simultaneously select multiple slave devices as it performs a transaction. For example, to enable communication with slave devices 1, 5, and 6, set bits 1, 5, and 6 of `slaveselct`. However, consideration is necessary to avoid signal contention between multiple slaves on their `mis0` outputs.

Upon reset, bit 0 is set to 1, and all other bits are cleared to 0. Thus, after a device reset, slave device 0 is automatically selected.

This chapter references [AN 350: Upgrading Nios Processor Systems to the Nios II Processor](#).

## Document Revision History

Table 10–6 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	<ul style="list-style-type: none"> <li>Chapter 10 was formerly chapter 9.</li> <li>Added “Referenced Document” on page 10–15.</li> </ul>	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>Chapter 9 was formerly chapter 7.</li> <li>Added table of contents to Overview section.</li> </ul>	—
March 2007 v7.0.0	No change from previous release.	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>Updated Avalon terminology because of changes to Avalon technologies</li> <li>Changed old “Avalon switch fabric” term to “system interconnect fabric”</li> <li>Changed old “Avalon interface” terms to “Avalon Memory-Mapped interface”</li> </ul>	For the 6.1 release, Altera released the Avalon Streaming interface, which necessitated some re-phrasing of existing Avalon terminology.
May 2006 v6.0.0	No change from previous release.	—
December 2005 v5.1.1	Changed Avalon “streaming” terminology to “flow control” based on a change to the <i>Avalon Interface Specification</i> .	—
October 2005 v5.1.0	No change from previous release.	—
May 2005 v5.0.0	No change from previous release. Previously in the Nios II Processor Reference Handbook.	—
September 2004 v1.1	Updates for Nios II 1.01 release.	—
May 2004 v1.0	Initial release.	—

---

This section describes display interface peripherals provided by Altera®. These components provide interfaces to visual display devices for SOPC Builder systems.

See *About This Handbook* for further details.

This section includes the following chapters:

- [Chapter 11, Optrex 16207 LCD Controller Core](#)
- [Chapter 12, Video Sync Generator and Pixel Converter Cores](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Core Overview

The Optrex 16207 LCD controller core with Avalon<sup>®</sup> Interface (“the LCD controller”) provides the hardware interface and software driver required for a Nios<sup>®</sup> II processor to display characters on an Optrex 16207 (or equivalent) 16×2-character LCD panel. Device drivers are provided in the HAL system library for the Nios II processor. Nios II programs access the LCD controller as a character mode device using ANSI C standard library routines, such as `printf()`. The LCD controller is SOPC Builder-ready, and integrates easily into any SOPC Builder-generated system.

The Nios II Embedded Design Suite (EDS) includes an Optrex LCD module and provide several ready-made example designs that display text on the Optrex 16207 via the LCD controller. For details about the Optrex 16207 LCD module, see the manufacturer’s *Dot Matrix Character LCD Module User’s Manual* available at [www.optrex.com](http://www.optrex.com).

This chapter contains the following sections:

- “Functional Description”
- “Device and Tools Support” on page 11–2
- “Instantiating the Core in SOPC Builder” on page 11–2
- “Software Programming Model” on page 11–2

## Functional Description

The LCD controller hardware consists of two user-visible components:

- Eleven signals that connect to pins on the Optrex 16207 LCD panel — These signals are defined in the Optrex 16207 data sheet.
  - E – Enable (output)
  - RS – Register Select (output)
  - R/W – Read or Write (output)
  - DB0 through DB7 – Data Bus (bidirectional)
- An Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to 4 registers — The HAL device drivers make it unnecessary for users to access the registers directly. Therefore, Altera does not provide details about the register usage. For further details, refer to “Software Programming Model” on page 11–2.

Figure 11-1 shows a block diagram of the LCD controller core.

**Figure 11-1. LCD Controller Block Diagram**

## Device and Tools Support

The LCD controller hardware supports all Altera FPGA families. The LCD controller drivers support the Nios II processor. The drivers do not support the first-generation Nios processor.

## Instantiating the Core in SOPC Builder

In SOPC Builder, the LCD controller component has the name Character LCD (16x2, Optrex 16207). The LCD controller does not have any user-configurable settings. The only choice to make in SOPC Builder is whether or not to add an LCD controller to the system. For each LCD controller included in the system, the top-level system module includes the 11 signals that connect to the LCD module.

## Software Programming Model

This section describes the software programming model for the LCD controller.

### HAL System Library Support

Altera provides HAL system library drivers for the Nios II processor that enable you to access the LCD controller using the ANSI C standard library functions. The Altera-provided drivers integrate into the HAL system library for Nios II systems. The LCD driver is a standard character-mode device, as described in the *Nios II Software Developer's Handbook*. Therefore, using `printf()` is the easiest way to write characters to the display.

The LCD driver requires that the HAL system library include the system clock driver.

## Displaying Characters on the LCD

The driver implements VT100 terminal-like behavior on a miniature scale for the 16×2 screen. Characters written to the LCD controller are stored to an 80-column × 2-row buffer maintained by the driver. As characters are written, the cursor position is updated. Visible characters move the cursor position to the right. Any visible characters written to the right of the buffer are discarded. The line feed character (\n) moves the cursor down one line and to the left-most column.

The buffer is scrolled up as soon as a printable character is written onto the line below the bottom of the buffer. Rows do not scroll as soon as the cursor moves down to allow the maximum useful information in the buffer to be displayed.

If the visible characters in the buffer will fit on the display, then all characters are displayed. If the buffer is wider than the display, then the display scrolls horizontally to display all the characters. Different lines scroll at different speeds, depending on the number of characters in each line of the buffer.

The LCD driver understands a small subset of ANSI and VT100 escape sequences that can be used to control the cursor position, and clear the display as shown in [Table 11–1](#).

<b>Sequence</b>	<b>Meaning</b>
BS (\b)	Moves the cursor to the left by one character.
CR (\r)	Moves the cursor to the start of the current line.
LF (\n)	Moves the cursor to the start of the line and move it down one line.
ESC ( (\x1B)	Starts a VT100 control sequence.
ESC [ <y> ; <x> H	Moves the cursor to the y, x position specified – positions are counted from the top left which is 1;1.
ESC [ K	Clears from current cursor position to end of line.
ESC [ 2 J	Clears the whole screen.

The LCD controller is an output-only device. Therefore, attempts to read from it will return immediately indicating that no characters have been received.

The LCD controller drivers are not included in the system library when the **Reduced device drivers** option is enabled for the system library. If you want to use the LCD controller while using small drivers for other devices, then add the preprocessor option `-DAL_T_USE_LCD_16207` to the preprocessor options.

## Software Files

The LCD controller is accompanied by the following software files. These files define the low-level interface to the hardware and provide the HAL drivers. Application developers should not modify these files.

- **altera\_avalon\_lcd\_16207\_regs.h** — This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_lcd\_16207.h, altera\_avalon\_lcd\_16207.c** — These files implement the LCD controller device drivers for the HAL system library.

## Register Map

The HAL device drivers make it unnecessary for you to access the registers directly. Therefore, Altera does not publish details about the register map. For more information, the **altera\_avalon\_lcd\_16207\_regs.h** file describes the register map, and the *Dot Matrix Character LCD Module User's Manual* from Optrex describes the register usage.

## Interrupt Behavior

The LCD controller does not generate interrupts. However, the LCD driver's text scrolling feature relies on the HAL system clock driver, which uses interrupts for timing purposes.

## Referenced Document

This chapter references the [Nios II Software Developer's Handbook](#).

## Document Revision History

Table 11–2 shows the revision history for this chapter.

## Core Overview

The video sync generator core accepts a continuous stream of pixel data in RGB format, and outputs the data to an off-chip display controller with proper timing. You can configure the video sync generator core to support different display resolutions and synchronization timings.

The pixel converter core transforms the pixel data to the format required by the video sync generator. [Figure 12–1](#) shows a typical placement of the video sync generator and pixel converter cores in a system.

In this example, the video buffer stores the pixel data in 32-bit unpacked format. The extra byte in the pixel data is discarded by the pixel converter core before the data is serialized and sent to the video sync generator core.

**Figure 12–1. Typical Placement in a System**

The video sync generator and pixel converter cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system.

These cores are deployed in the Nios II Embedded Software Evaluation Kit (EEK), which includes an LCD display daughtercard assembly attached via an HSMC connector.

This chapter contains the following sections:

- [“Video Sync Generator” on page 12–2](#)
- [“Pixel Converter” on page 12–5](#)
- [“Device and Tools Support” on page 12–6](#)
- [“Hardware Simulation Considerations” on page 12–7](#)

## Video Sync Generator

This section describes the hardware structure and functionality of the video sync generator core.

### Functional Description

The video sync generator core adds horizontal and vertical synchronization signals to the pixel data that comes through its Avalon-ST input interface and outputs the data to an off-chip display controller. No processing or validation is performed on the pixel data. [Figure 12–2](#) shows a block diagram of the video sync generator.

**Figure 12–2. Video Sync Generator Block Diagram**

You can configure various aspects of the core and its Avalon-ST interface to suit your requirements. You can specify the data width, number of beats required to transfer each pixel and synchronization signals. See [“Instantiating the Core in SOPC Builder”](#) on page 12–3 for more information on the available options.

To ensure incoming pixel data is sent to the display controller with correct timing, the video sync generator core must synchronize itself to the first pixel in a frame. The first active pixel is indicated by an *sop* pulse.

The video sync generator core expects continuous streams of pixel data at its input interface and assumes that each incoming packet contains the correct number of pixels (Number of rows \* Number of columns). Data starvation disrupts synchronization and results in unexpected output on the display.

## Instantiating the Core in SOPC Builder

Use the MegaWizard® interface for the video sync generator core in SOPC Builder to configure the core. Table 12–1 lists the available parameters in the MegaWizard interface.

<i>Table 12–1. Video Sync Generator Parameters</i>	
Parameter Name	Description
<b>Data Stream Bit Width</b>	The width of the inbound and outbound data.
<b>Beats Per Pixel</b>	The number of beats required to transfer one pixel. Valid values are 1 and 3. This parameter, when multiplied by <b>Data Stream Bit Width</b> must be equal to the total number of bits in one pixel.
<b>Number of Columns</b>	The number of active pixels in each line.
<b>Number of Rows</b>	The number of active scan lines in each video frame.
<b>Horizontal Blank Pixels</b>	The number of blanking pixels that precede the active pixels. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
<b>Horizontal Front Porch Pixels</b>	The number of blanking pixels that follow the active pixels. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
<b>Vertical Blank Lines</b>	The number of blanking lines that precede the active lines. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
<b>Vertical Front Porch Pixels</b>	The number of blanking lines that follow the active lines. During this period, there is no data flow from the Avalon-ST sink port to the LCD output data port.
<b>Total Horizontal Scan Pixels</b>	The total number of pixels in one line. The value is the sum of the following parameters: <b>Number of Columns</b> , <b>Horizontal Blank Pixel</b> , and <b>Horizontal Front Porch Pixels</b> .
<b>Total Vertical Scan Lines</b>	The total number of lines in one video frame. The value is the sum of the following parameters: <b>Number of Rows</b> , <b>Vertical Blank Lines</b> , and <b>Vertical Front Porch Lines</b> .

## Signals

Table 12–2 lists the input and output signals for the video sync generator core.

<i>Table 12–2. Video Sync Generator Core Signals (Part 1 of 2)</i>			
Signal Name	Width (Bits)	Direction	Description
<b>Global Signals</b>			
clk	1	Input	System clock.
reset	1	Input	System reset.
<b>Avalon-ST Signals</b>			

<b>Table 12–2. Video Sync Generator Core Signals (Part 2 of 2)</b>			
<b>Signal Name</b>	<b>Width (Bits)</b>	<b>Direction</b>	<b>Description</b>
data	Variable-width	Input	Incoming pixel data. The datawidth is determined by the parameter <b>Data Stream Bit Width</b> .
ready	1	Output	This signal is asserted when the video sync generator is ready to receive the pixel data.
valid	1	Input	This signal is not used by the video sync generator core because the core always expects valid pixel data on the next clock cycle after the <code>ready</code> signal is asserted.
sop	1	Input	Start-of-packet. This signal is asserted when the first pixel is received.
eop	1	Input	End-of-packet. This signal is asserted when the last pixel is received.
<b>LCD Output Signals</b>			
rgb_out	Variable-width	Output	Display data. The datawidth is determined by the parameter <b>Data Stream Bit Width</b> .
hd	1	Output	Horizontal synchronization pulse for display.
vd	1	Output	Vertical synchronization pulse for display.
den	1	Output	This signal is asserted when the video sync generator core outputs valid data for display.

## Timing Diagrams

The horizontal and vertical synchronization timings are determined by the parameters setting. Figure 12–3 shows the horizontal synchronization timing when the parameters **Data Stream Bit Width** and **Beats Per Pixel** are set to 8 and 3, respectively.

**Figure 12–3. Horizontal Synchronization Timing—8 bits DataWidth and 3 Beats Per Pixel**

Figure 12–4 shows the horizontal synchronization timing when the parameters **Data Stream Bit Width** and **Beats Per Pixel** are set to 24 and 1, respectively.

**Figure 12–4. Horizontal Synchronization Timing—24 bits Datwidth and 1 Beat Per Pixel**

Figure 12–5 shows the vertical synchronization timing.

**Figure 12–5. Vertical Synchronization Timing**

## Pixel Converter

This section describes the hardware structure and functionality of the pixel converter core.

### Functional Description

The pixel converter core receives pixel data on its Avalon-ST input interface and transforms the pixel data to the format required by the video sync generator. The least significant byte of the 32-bit wide pixel data is removed and the remaining 24 bits are wired directly to the core's Avalon-ST output interface.

## Instantiating the Core in SOPC Builder

Use the MegaWizard interface for the pixel converter core in SOPC Builder to add the core to a system. There are no user-configurable settings for this core.

## Signals

Table 12-3 lists the input and output signals for the pixel converter core.

<i>Table 12-3. Pixel Converter Input Interface Signals</i>			
Signal Name	Width (Bits)	Direction	Description
<b>Global Signals</b>			
clk	1	Input	Not in use.
reset_n	1	Input	
<b>Avalon-ST Signals</b>			
data_in	32	Input	Incoming pixel data. Contains four 8-bit symbols that are transferred in 1 beat.
data_out	24	Output	Output data. Contains three 8-bit symbols that are transferred in 1 beat.
sop_in	1	Input	Wired directly to the corresponding output signals.
eop_in	1	Input	
ready_in	1	Input	
valid_in	1	Input	
empty_in	1	Input	
sop_out	1	Output	Wired directly from the input signals.
eop_out	1	Output	
ready_out	1	Output	
valid_out	1	Output	
empty_out	1	Output	

## Device and Tools Support

The video sync generator and pixel converter cores support all Altera device families.

## Hardware Simulation Considerations

For a typical 60 Hz refresh rate, set the simulation length for the video sync generator core to at least 16.7 ms to get a full video frame. Depending on the size of the video frame, simulation may take a very long time to complete.

## Referenced Document

This chapter references the *Avalon Streaming Interface Specification*.

## Document Revision History

Table 12–4 shows the revision history for this chapter.

<i>Table 12–4. Document Revision History</i>		
<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	Initial release.	—

## Section IV. Multiprocessor Coordination Peripherals

This section describes multiprocessor coordination peripherals provided by Altera® for SOPC Builder systems. These components provide reliable mechanisms for multiple Nios® II processors to communicate with each other, and coordinate operations.

See *About This Handbook* for further details.

This section includes the following chapters:

- [Chapter 13, Mutex Core](#)
- [Chapter 14, Mailbox Core](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Core Overview

Multiprocessor environments can use the mutex core with Avalon<sup>®</sup> interface to coordinate accesses to a shared resource. The mutex core provides a protocol to ensure mutually exclusive ownership of a shared resource.

The mutex core provides a hardware-based atomic test-and-set operation, allowing software in a multiprocessor environment to determine which processor owns the mutex. The mutex core can be used in conjunction with shared memory to implement additional interprocessor coordination features, such as mailboxes and software mutexes.

The mutex core is designed for use in Avalon-based processor systems, such as a Nios<sup>®</sup> II processor system. Altera provides device drivers for the Nios II processor to enable use of the hardware mutex.

The mutex core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [Functional Description](#)
- [“Device and Tools Support” on page 13–2](#)
- [“Instantiating the Core in SOPC Builder” on page 13–2](#)
- [“Software Programming Model” on page 13–2](#)
- [“Mutex API” on page 13–4](#)

## Functional Description

The mutex core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to two memory-mapped, 32-bit registers. [Table 13–1](#) shows the registers.

<i>Table 13–1. Mutex Core Register Map</i>					
Offset	Register Name	R/W	Bit Description		
			31 ... 16	15 ... 1	0
0	mutex	RW	OWNER	VALUE	
1	reset	RW	–	–	RESET

The mutex core has the following basic behavior. This description assumes there are multiple processors accessing a single mutex core, and each processor has a unique identifier (ID).

- When the VALUE field is 0x0000, the mutex is available (i.e., unlocked). Otherwise, the mutex is unavailable (i.e., locked).
- The mutex register is always readable. A processor (or any Avalon-MM master peripheral) can read the mutex register to determine its current state.
- The mutex register is writable only under specific conditions. A write operation changes the mutex register only if one or both of the following conditions is true:
  - The VALUE field of the mutex register is zero.
  - The OWNER field of the mutex register matches the OWNER field in the data to be written.
- A processor attempts to acquire the mutex by writing its ID to the OWNER field, and writing a non-zero value to VALUE. The processor then checks if the acquisition succeeded by verifying the OWNER field.
- After system reset, the RESET bit in the reset register is high. Writing a one to this bit clears it.

## Device and Tools Support

The mutex core supports all Altera device families supported by SOPC Builder, and provides device drivers for the Nios II hardware abstraction layer (HAL) system library.

## Instantiating the Core in SOPC Builder

Hardware designers use the MegaWizard® interface for the mutex core in SOPC Builder to specify the core's hardware features. The MegaWizard interface provides the following options:

- **Initial Value**—the initial contents of the VALUE field after reset. If the **Initial Value** setting is non-zero, you must also specify **Initial Owner**.
- **Initial Owner**—the initial contents of the OWNER field after reset. When **Initial Owner** is specified, this owner must release the mutex before it can be acquired by another owner.

## Software Programming Model

The following sections describe the software programming model for the mutex core, such as the software constructs used to access the hardware. For Nios II processor users, Altera provides routines to access the mutex core hardware. These functions are specific to the mutex core and directly manipulate low-level hardware. The mutex core cannot be accessed via the HAL API or the ANSI C standard library. In Nios II processor systems, a processor locks the mutex by writing the value of its `cpu_id` control register to the OWNER field of the mutex register.

## Software Files

Altera provides the following software files accompanying the mutex core:

- **altera\_avalon\_mutex\_regs.h**—this file defines the core’s register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_mutex.h**—this file defines data structures and functions to access the mutex core hardware.
- **altera\_avalon\_mutex.c**—this file contains the implementations of the functions to access the mutex core

## Hardware Mutex

This section describes the low-level software constructs for manipulating the mutex core hardware.

The file **altera\_avalon\_mutex.h** declares a structure `alt_mutex_dev` that represents an instance of a mutex device. It also declares functions for accessing the mutex hardware structure, listed in [Table 13–2](#).

<b>Table 13–2. Hardware Mutex Functions</b>	
<b>Function Name</b>	<b>Description</b>
<code>altera_avalon_mutex_open()</code>	Claims a handle to a mutex, enabling all the other functions to access the mutex core.
<code>altera_avalon_mutex_trylock()</code>	Tries to lock the mutex. Returns immediately if it fails to lock the mutex.
<code>altera_avalon_mutex_lock()</code>	Locks the mutex. Will not return until it has successfully claimed the mutex.
<code>altera_avalon_mutex_unlock()</code>	Unlocks the mutex.
<code>altera_avalon_mutex_is_mine()</code>	Determines if this CPU owns the mutex.
<code>altera_avalon_mutex_first_lock()</code>	Tests whether the mutex has been released since reset.

These routines coordinate access to the software mutex structure using a hardware mutex core. For a complete description of each function, see section [“Mutex API” on page 13–4](#).

Example 13-1 demonstrates opening a mutex device handle and locking a mutex:

---

**Example 13-1. Opening and locking a mutex**

```
#include <altera_avalon_mutex.h>

/* get the mutex device handle */
alt_mutex_dev* mutex = altera_avalon_mutex_open( "/dev/mutex" );

/* acquire the mutex, setting the value to one */
altera_avalon_mutex_lock( mutex, 1 );

/*
 * Access a shared resource here.
 */

/* release the lock */
altera_avalon_mutex_unlock( mutex );
```

---

## Mutex API

This section describes the application programming interface (API) for the mutex core.

---

## altera\_avalon\_mutex\_is\_mine()

**Prototype:** `int altera_avalon_mutex_is_mine(alt_mutex_dev* dev)`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mutex.h>`

**Parameters:** `dev`—the mutex device to test.

**Returns:** Returns non zero if the mutex is owned by this CPU.

**Description:** `altera_avalon_mutex_is_mine()` determines if this CPU owns the mutex.

## altera\_avalon\_mutex\_first\_lock()

**Prototype:** `int altera_avalon_mutex_first_lock(alt_mutex_dev* dev)`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mutex.h>`

**Parameters:** `dev`—the mutex device to test.

**Returns:** Returns 1 if this mutex has not been released since reset, otherwise returns 0.

**Description:** `altera_avalon_mutex_first_lock()` determines whether this mutex has been released since reset.

---

## altera\_avalon\_mutex\_lock()

**Prototype:**            `void altera_avalon_mutex_lock(alt_mutex_dev* dev, alt_u32 value)`

**Thread-safe:**        Yes.

**Available from ISR:** No.

**Include:**            `<altera_avalon_mutex.h>`

**Parameters:**        `dev`—the mutex device to acquire.  
`value`—the new value to write to the mutex.

**Returns:**            —

**Description:**        `altera_avalon_mutex_lock()` is a blocking routine that acquires a hardware mutex, and at the same time, loads the mutex with the `value` parameter.

## altera\_avalon\_mutex\_open()

**Prototype:** `alt_mutex_dev* alt_hardware_mutex_open(const char* name)`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mutex.h>`

**Parameters:** `name`—the name of the mutex device to open.

**Returns:** A pointer to the mutex device structure associated with the supplied name, or NULL if no corresponding mutex device structure was found.

**Description:** `altera_avalon_mutex_open()` retrieves a pointer to a hardware mutex device structure.

---

## altera\_avalon\_mutex\_trylock()

**Prototype:** `int altera_avalon_mutex_trylock(alt_mutex_dev* dev, alt_u32 value)`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mutex.h>`

**Parameters:** `dev`—the mutex device to lock.  
`value`—the new value to write to the mutex.

**Returns:** Zero if the mutex was successfully locked, or non zero if the mutex was not locked.

**Description:** `altera_avalon_mutex_trylock()` tries once to lock the hardware mutex, and returns immediately.

## altera\_avalon\_mutex\_unlock()

**Prototype:**            void altera\_avalon\_mutex\_unlock(alt\_mutex\_dev\* dev)

**Thread-safe:**         Yes.

**Available from ISR:** No.

**Include:**             <altera\_avalon\_mutex.h>

**Parameters:**         dev—the mutex device to unlock.

**Returns:**             -

**Description:**        altera\_avalon\_mutex\_unlock() releases a hardware mutex device. Upon release, the value stored in the mutex is set to zero. If the caller does not hold the mutex, the behavior of this function is undefined.

## Document Revision History

## Core Overview

Multiprocessor environments can use the mailbox core with Avalon® interface to send messages between processors.

The mailbox core contains mutexes to ensure that only one processor modifies the mailbox contents at a time. The mailbox core must be used in conjunction with a separate shared memory that is used for storing the actual messages.

The mailbox core is designed for use in Avalon-based processor systems, such as a Nios® II processor system. Altera® provides device drivers for the Nios II processor. The mailbox core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [“Functional Description”](#)
- [“Device and Tools Support” on page 14-2](#)
- [“Instantiating the Core in SOPC Builder” on page 14-2](#)
- [“Software Programming Model” on page 14-3](#)
- [“Mailbox API” on page 14-6](#)

## Functional Description

The mailbox core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to four memory-mapped, 32-bit registers. [Table 14-1](#) shows the registers.

**Table 14-1. Mutex Core Register Map**

Offset	Register Name	R/W	Bit Description		
			31 ... 16	15 ... 1	0
0	mutex0	RW	OWNER	VALUE	
1	reset0	RW	–	–	RESET
2	mutex1	RW	OWNER	VALUE	
3	reset1	RW	–	–	RESET

The mailbox component contains two mutexes: One to ensure unique write access to shared memory and one to ensure unique read access from shared memory. The mailbox core is used in conjunction with a separate memory in the system that is shared among multiple processors.

Mailbox functionality using the mutexes and memory is implemented entirely in the software. Refer to [“Software Programming Model” on page 14–3](#) for details about how to use the mailbox core in software.

For a detailed description of the mutex hardware operation, refer to the Mutex Core chapter in volume 5 of the *Quartus II Handbook*.

## Device and Tools Support

The mailbox core supports all Altera device families supported by SOPC Builder, and provides device drivers for the Nios II hardware abstraction layer (HAL) system library.

## Instantiating the Core in SOPC Builder

Hardware designers instantiate and configure the mailbox core in an SOPC Builder system using the following process:

1. Decide which processors will share the mailbox.
2. On the SOPC Builder **System Contents** tab, instantiate a memory component to serve as the mailbox buffer. Any RAM can be used as the mailbox buffer. The mailbox buffer can share space in an existing memory, such as program memory; it does not require a dedicated memory.
3. On the SOPC Builder **System Contents** tab, instantiate the mailbox component. The mailbox MegaWizard® interface presents the following options:
  - **Memory module**—Specifies which memory to use for the mailbox buffer. If the **Memory module** list does not contain the desired shared memory, the memory is not connected in the system correctly. Refer to Step 4 on [page 14–3](#).
  - **CPUs available with this memory**—Shows all the processors that can share the mailbox. This field is always read-only. Use it to verify that the processor connections are correct. If a processor that needs to share the mailbox is missing from the list, refer to Step 4 on [page 14–3](#).
  - **Shared mailbox memory offset**—Specifies an offset into the memory. The mailbox message buffer starts at this offset.
  - **Mailbox size (bytes)**—Specifies the number of bytes to use for the mailbox message buffer. The Nios II driver software provided by Altera uses eight bytes of overhead to implement the mailbox functionality. For a mailbox capable of passing only

- one message at a time, **Mailbox size (bytes)** must be at least 12 bytes.
- **Maximum available bytes**—Specifies the number of bytes in the selected memory available for use as the mailbox message buffer. This field is always read-only.
4. If not already connected, make component connections on the SOPC Builder **System Contents** tab.
    - a. Connect each processor's data bus master port to the mailbox slave port.
    - b. Connect each processor's data bus master port to the shared mailbox memory.

## Software Programming Model

The following sections describe the software programming model for the mailbox core, such as the software constructs used to access the hardware. For Nios II processor users, Altera provides routines to access the mailbox core hardware. These functions are specific to the mailbox core and directly manipulate low-level hardware.

The mailbox software programming model has the following characteristics and assumes there are multiple processors accessing a single mailbox core and a shared memory:

- Each mailbox message is one 32-bit word.
- There is a predefined address range in shared memory dedicated to storing messages. The size of this address range imposes a maximum limit on the number of messages pending.
- The mailbox software implements a message FIFO between processors. Only one processor can write to the mailbox at a time, and only one processor can read from the mailbox at a time, ensuring message integrity.
- The software on both the sending and receiving processors must agree on a protocol for interpreting mailbox messages. Typically, processors treat the message as a pointer to a structure in shared memory.
- The sending processor can post messages in succession, up to the limit imposed by the size of the message address range.
- When messages exist in the mailbox, the receiving processor can read messages. The receiving processor can block until a message appears, or it can poll the mailbox for new messages.
- Reading the message removes the message from the mailbox.

## Software Files

Altera provides the following software files accompanying the mailbox core hardware:

- **altera\_avalon\_mailbox\_regs.h**—Defines the core’s register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_mailbox.h**—Defines data structures and functions to access the mailbox core hardware.
- **altera\_avalon\_mailbox.c**—Contains the implementations of the functions to access the mailbox core.

## Programming with the Mailbox Core

This section describes the software constructs for manipulating the mailbox core hardware.

The file **altera\_avalon\_mailbox.h** declares a structure `alt_mailbox_dev` that represents an instance of a mailbox device. It also declares functions for accessing the mailbox hardware structure, listed in [Table 14–2](#). For a complete description of each function, refer to [“Mailbox API” on page 14–6](#).

<i>Table 14–2. Mailbox API Functions</i>	
Function Name	Description
<code>altera_avalon_mailbox_close()</code>	Closes the handle to a mailbox.
<code>altera_avalon_mailbox_get()</code>	Returns a message if one is present, but does not block waiting for a message.
<code>altera_avalon_mailbox_open()</code>	Claims a handle to a mailbox, enabling all the other functions to access the mailbox core.
<code>altera_avalon_mailbox_pend()</code>	Blocks waiting for a message to be in the mailbox.
<code>altera_avalon_mailbox_post()</code>	Posts a message to the mailbox.

**Example 14-1** demonstrates writing to and reading from a mailbox. For this example, assume that the hardware system has two processors communicating via mailboxes. The system includes two mailbox cores, which provide two-way communication between the processors.

---

**Example 14-1. Example: Writing to and Reading from a Mailbox**

```
#include <stdio.h>
#include "altera_avalon_mailbox.h"

int main()
{
    alt_u32 message = 0;
    alt_mailbox_dev* send_dev, rcv_dev;
    /* Open the two mailboxes between this processor and another */
    send_dev = altera_avalon_mailbox_open("/dev/mailbox_0");
    rcv_dev = altera_avalon_mailbox_open("/dev/mailbox_1");

    while(1)
    {
        /* Send a message to the other processor */
        altera_avalon_mailbox_post(send_dev, message);

        /* Wait for the other processor to send a message back */
        message = altera_avalon_mailbox_pend(rcv_dev);
    }

    return 0;
}
```

---

## Mailbox API

This section describes the application programming interface (API) for the mailbox core.

## altera\_avalon\_mailbox\_close()

**Prototype:** `void altera_avalon_mailbox_close (alt_mailbox_dev* dev);`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mailbox.h>`

**Parameters:** `dev`—the mailbox to close.

**Returns:** —

**Description:** `altera_avalon_mailbox_close()` closes the mailbox.

## altera\_avalon\_mailbox\_get()

- Prototype:** `alt_u32 altera_avalon_mailbox_get (alt_mailbox_dev* dev, int* err);`
- Thread-safe:** Yes.
- Available from ISR:** No.
- Include:** `<altera_avalon_mailbox.h>`
- Parameters:** `dev`—the mailbox handle,  
`err`—pointer to an error code that is returned.
- Returns:** Returns a message if one is available in the mailbox, otherwise returns 0. The value pointed to by `err` is 0 if the message was read correctly, or `EWOULDBLOCK` if there is no message to read.
- Description:** `altera_avalon_mailbox_get()` returns a message if one is present, but does not block waiting for a message.

---

## altera\_avalon\_mailbox\_open()

**Prototype:** `alt_mailbox_dev* altera_avalon_mailbox_open (const char* name);`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mailbox.h>`

**Parameters:** `name`—the name of the mailbox device to open.

**Returns:** Returns a handle to the mailbox, or NULL if this mailbox does not exist.

**Description:** `altera_avalon_mailbox_open()` opens a mailbox.

## altera\_avalon\_mailbox\_pend()

**Prototype:** `alt_u32 altera_avalon_mailbox_pend (alt_mailbox_dev* dev);`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mailbox.h>`

**Parameters:** `dev`—the mailbox device to read a message from.

**Returns:** Returns the message.

**Description:** `altera_avalon_mailbox_pend()` is a blocking routine that waits for a message to appear in the mailbox and then reads it.

---

## altera\_avalon\_mailbox\_post()

**Prototype:** `int altera_avalon_mailbox_post (alt_mailbox_dev* dev, alt_u32 msg);`

**Thread-safe:** Yes.

**Available from ISR:** No.

**Include:** `<altera_avalon_mailbox.h>`

**Parameters:** `dev`—the mailbox device to post a message to  
`msg`—the value to post.

**Returns:** Returns 0 on success, or `EWOULDBLOCK` if the mailbox is full.

**Description:** `altera_avalon_mailbox_post()` posts a message to the mailbox.

This section describes other peripherals provided by Altera® for SOPC Builder systems.

See *About This Handbook* for further details.

This section includes the following chapters:

- Chapter 15, PIO Core
- Chapter 16, Timer Core
- Chapter 17, System ID Core
- Chapter 18, PLL Core
- Chapter 19, Performance Counter Core

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

## Core Overview

The parallel input/output (PIO) core with Avalon® interface provides a memory-mapped interface between an Avalon Memory-Mapped (Avalon-MM) slave port and general-purpose I/O ports. The I/O ports connect either to on-chip user logic, or to I/O pins that connect to devices external to the FPGA.

The PIO core provides easy I/O access to user logic or external devices in situations where a “bit banging” approach is sufficient. Some example uses are:

- Controlling LEDs
- Acquiring data from switches
- Controlling display devices
- Configuring and communicating with off-chip devices, such as application-specific standard products (ASSP)

The PIO core interrupt request (IRQ) output can assert an interrupt based on input signals. The PIO core is SOPC Builder ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [Functional Description](#)
- [“Example Configurations” on page 15–4](#)
- [“Instantiating the PIO Core in SOPC Builder” on page 15–5](#)
- [“Device and Tools Support” on page 15–6](#)
- [“Software Programming Model” on page 15–6](#)

## Functional Description

Each PIO core can provide up to 32 I/O ports. An intelligent host such as a microprocessor controls the PIO ports by reading and writing the register-mapped Avalon-MM interface. Under control of the host, the PIO core captures data on its inputs and drives data to its outputs. When the PIO ports are connected directly to I/O pins, the host can tristate the pins by writing control registers in the PIO core. [Figure 15–1](#) shows an example of a processor-based system that uses multiple PIO cores to blink LEDs, capture edges from on-chip reset-request control logic, and control an off-chip LCD display.

Figure 15–1. An Example System Using Multiple PIO Cores

When integrated into an SOPC Builder-generated system, the PIO core has two user-visible features:

- A memory-mapped register space with four registers: data, direction, interruptmask, and edgecapture.
- 1 to 32 I/O ports.

The I/O ports can be connected to logic inside the FPGA, or to device pins that connect to off-chip devices. The registers provide an interface to the I/O ports via the Avalon-MM interface. See [Table 15–2 on page 15–7](#) for a description of the registers. Some registers are not necessary in certain hardware configurations, in which case the unnecessary registers do not exist. Reading a non-existent register returns an undefined value, and writing a non-existent register has no effect.

## Data Input and Output

The PIO core I/O ports can connect to either on-chip or off-chip logic. The core can be configured with inputs only, outputs only, or both inputs and outputs. If the core will be used to control bidirectional I/O pins on the device, the core provides a bidirectional mode with tristate control.

The hardware logic is separate for reading and writing the data register. Reading the data register returns the value present on the input ports (if present). Writing data affects the value driven to the output ports (if present). These ports are independent; reading the data register does not return previously-written data.

## Edge Capture

The PIO core can be configured to capture edges on its input ports. It can capture low-to-high transitions, high-to-low transitions, or both. Whenever an input detects an edge, the condition is indicated in the edgecapture register. The type of edges to detect is specified at system generation time, and cannot be changed via the registers.

## IRQ Generation

The PIO core can be configured to generate an IRQ on certain input conditions. The IRQ conditions can be either:

- *Level-sensitive*—The PIO core hardware can detect a high level. A NOT gate can be inserted external to the core to provide negative sensitivity.
- *Edge-sensitive*—The core's edge capture configuration determines which type of edge causes an IRQ

Interrupts are individually maskable for each input port. The interrupt mask determines which input port can generate interrupts.

## Example Configurations

Figure 15–2 shows a block diagram of the PIO core configured with input and output ports, as well as support for IRQs.

**Figure 15–2. PIO Core with Input Ports, Output Ports and IRQ Support**

Figure 15–3 shows a block diagram of the PIO core configured in bidirectional mode, without support for IRQs.

**Figure 15–3. PIO Core with Bidirectional Ports**

### Avalon-MM Interface

The PIO core’s Avalon-MM interface consists of a single Avalon-MM slave port. The slave port is capable of fundamental Avalon-MM read and write transfers. The Avalon-MM slave port provides an IRQ output so that the core can assert interrupts.

## Instantiating the PIO Core in SOPC Builder

Designers use the MegaWizard® interface for the PIO core in SOPC Builder to configure the hardware feature set. The following sections describe the available options.

The MegaWizard interface has two tabs, **Basic Settings** and **Input Options**.

### Basic Settings

The **Basic Settings** page allows the designer to specify the width and direction of the I/O ports.

- The **Width** setting can be any integer value between 1 and 32. For a value of  $n$ , the I/O ports become  $n$ -bits wide.
- The **Direction** setting has four options, as shown in [Table 15–1](#).

Setting	Description
Bidirectional (tristate) ports	In this mode, each PIO bit shares one device pin for driving and capturing data. The direction of each pin is individually selectable. To tristate an FPGA I/O pin, set the direction to input.
Input ports only	In this mode the PIO ports can capture input only.
Output ports only	In this mode the PIO ports can drive output only.
Both input and output ports	In this mode, the input and output ports buses are separate, unidirectional buses of $n$ bits wide.

### Input Options

The **Input Options** page allows the designer to specify edge-capture and IRQ generation settings. The **Input Options** page is not available when **Output ports only** is selected on the **Basic Settings** page.

#### *Edge Capture Register*

#### Synchronously Capture

When **Synchronously capture** is on, the PIO core contains the edge capture register, `edgecapture`. The user must further specify what type of edge(s) to detect:

- **Rising Edge**
- **Falling Edge**
- **Either Edge**

The edge capture register allows the core to detect and (optionally) generate an interrupt when an edge of the specified type occurs on an input port.

When **Synchronously capture** is off, the `edgecapture` register does not exist.

#### Enable Bit Clearing for Edge Capture Register

Turning on **Enable bit-clearing for edge capture register** allows you to clear individual bit(s) in the edge capture register. To clear a given bit, write 1 to the bit in the edge capture register. Example—To clear bit 6 in the edge capture register, write 01000000 to the register.

#### *Interrupt*

When **Generate IRQ** is on, the PIO core is able to assert an IRQ output when a specified event occurs on input ports. The user must further specify the cause of an IRQ event:

- **Level**—The core generates an IRQ whenever a specific input is high and interrupts are enabled for that input in the `interruptmask` register.
- **Edge**—The core generates an IRQ whenever a specific bit in the edge capture register is high and interrupts are enabled for that bit in the `interruptmask` register.

When **Generate IRQ** is off, the `interruptmask` register does not exist.

## Device and Tools Support

The PIO core supports all Altera® FPGA families.

## Software Programming Model

This section describes the software programming model for the PIO core, including the register map and software constructs used to access the hardware. For Nios® II processor users, Altera provides the HAL system library header file that defines the PIO core registers. The PIO core does not match the generic device model categories supported by the HAL, so it cannot be accessed via the HAL API or the ANSI C standard library.

The Nios II Embedded Design Suite (EDS) provides several example designs that demonstrate usage of the PIO core. In particular, the `count_binary.c` example uses the PIO core to drive LEDs, and detect button presses using PIO edge-detect interrupts.

## Software Files

The PIO core is accompanied by one software file, `altera_avalon_pio_regs.h`. This file defines the core's register map, providing symbolic constants to access the low-level hardware.

## Legacy SDK Routines

The PIO core is supported by the legacy SDK routines for the first-generation Nios processor. For details about these routines, refer to the PIO documentation that accompanied the first-generation Nios processor.

For details about upgrading programs based on the legacy SDK to the HAL system library API, refer to *AN 350: Upgrading Nios Processor Systems to the Nios II Processor*.

## Register Map

An Avalon-MM master peripheral, such as a CPU, controls and communicates with the PIO core via the four 32-bit registers, shown in [Table 15–2](#). The table assumes that the PIO core's I/O ports are configured to a width of  $n$  bits.

Offset	Register Name		R/W	(n-1)	...	2	1	0
0	data	read access	R	Data value currently on PIO inputs				
		write access	W	New value to drive on PIO outputs				
1	direction (1)		R/W	Individual direction control for each I/O port. A value of 0 sets the direction to input; 1 sets the direction to output.				
2	interruptmask (1)		R/W	IRQ enable/disable for each input port. Setting a bit to 1 enables interrupts for the corresponding port.				
3	edgecapture (1), (2)		R/W	Edge detection for each input port.				

### Notes to [Table 15–2](#):

- (1) This register may not exist, depending on the hardware configuration. If a register is not present, reading the register returns an undefined value, and writing the register has no effect.
- (2) Writing any value to `edgecapture` clears all bits to 0.

### *data Register*

Reading from `data` returns the value present at the input ports. If the PIO core hardware is configured in output-only mode, reading from `data` returns an undefined value.

Writing to `data` stores the value to a register that drives the output ports. If the PIO core hardware is configured in input-only mode, writing to `data` has no effect. If the PIO core hardware is in bidirectional mode, the registered value appears on an output port only when the corresponding bit in the `direction` register is set to 1 (output).

### *direction Register*

The `direction` register controls the data direction for each PIO port, assuming the port is bidirectional. When bit  $n$  in `direction` is set to 1, port  $n$  drives out the value in the corresponding bit of the `data` register.

The `direction` register only exists when the PIO core hardware is configured in bidirectional mode. The mode (input, output, or bidirectional) is specified at system generation time, and cannot be changed at runtime. In input-only or output-only mode, the `direction` register does not exist. In this case, reading `direction` returns an undefined value, writing `direction` has no effect.

After reset, all bits of `direction` are 0, so that all bidirectional I/O ports are configured as inputs. If those PIO ports are connected to device pins, the pins are held in a high-impedance state. In bi-directional mode, to change the direction of the PIO port re-program the `direction` register.

### *interruptmask Register*

Setting a bit in the `interruptmask` register to 1 enables interrupts for the corresponding PIO input port. Interrupt behavior depends on the hardware configuration of the PIO core. See [“Interrupt Behavior” on page 15–9](#).

The `interruptmask` register only exists when the hardware is configured to generate IRQs. If the core cannot generate IRQs, reading `interruptmask` returns an undefined value, and writing to `interruptmask` has no effect.

After reset, all bits of `interruptmask` are zero, so that interrupts are disabled for all PIO ports.

### *edgecapture Register*

Bit  $n$  in the `edgecapture` register is set to 1 whenever an edge is detected on input port  $n$ . An Avalon-MM master peripheral can read the `edgecapture` register to determine if an edge has occurred on any of the PIO input ports. Writing any value to `edgecapture` clears all bits in the register.

The type of edge(s) to detect is fixed in hardware at system generation time. The `edgecapture` register only exists when the hardware is configured to capture edges. If the core is not configured to capture edges, reading from `edgecapture` returns an undefined value, and writing to `edgecapture` has no effect.

## Interrupt Behavior

The PIO core outputs a single IRQ signal that can connect to any master peripheral in the system. The master can read either the `data` register or the `edgecapture` register to determine which input port caused the interrupt.

When the hardware is configured for level-sensitive interrupts, the IRQ is asserted whenever corresponding bits in the `data` and `interruptmask` registers are 1. When the hardware is configured for edge-sensitive interrupts, the IRQ is asserted whenever corresponding bits in the `edgecapture` and `interruptmask` registers are 1. The IRQ remains asserted until explicitly acknowledged by disabling the appropriate bit(s) in `interruptmask`, or by writing to `edgecapture`.

## Software Files

The PIO core is accompanied by the following software file. This file provide low-level access to the hardware. Application developers should not modify the file.

- **`altera_avalon_pio_regs.h`**—This file defines the core’s register map, providing symbolic constants to access the low-level hardware. The symbols in this file are used by device driver functions.

## Core Overview

The timer core with Avalon® interface is a 32-bit interval timer for Avalon-based processor systems, such as a Nios® II processor system. The timer provides the following features:

- Controls to start, stop, and reset the timer
- Two count modes: count down once and continuous count-down
- Count-down period register
- Maskable interrupt request (IRQ) upon reaching zero
- Optional watchdog timer feature that resets the system if timer ever reaches zero
- Optional periodic pulse generator feature that outputs a pulse when timer reaches zero
- Compatible with 32-bit and 16-bit processors

Device drivers are provided in the HAL system library for the Nios II processor. The timer core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- [“Functional Description” on page 16–2](#)
- [“Device and Tools Support” on page 16–3](#)
- [“Instantiating the Core in SOPC Builder” on page 16–3](#)
- [“Software Programming Model” on page 16–6](#)

## Functional Description

Figure 16–1 shows a block diagram of the timer core.

Figure 16–1. Timer Core Block Diagram

The timer core has two user-visible features:

- The Avalon Memory-Mapped (Avalon-MM) interface that provides access to six 16-bit registers
- An optional pulse output that can be used as a periodic pulse generator

All registers are 16-bits wide, making the timer compatible with both 16-bit and 32-bit processors. Certain registers only exist in hardware for a given configuration. For example, if the timer is configured with a fixed period, the period registers do not exist in hardware.

The basic behavior of the timer is described below:

- An Avalon-MM master peripheral, such as a Nios II processor, writes the timer core's `control` register to:
  - Start and stop the timer
  - Enable/disable the IRQ
  - Specify count-down once or continuous count-down mode
- A processor reads the `status` register for information about current timer activity.
- A processor can specify the timer period by writing a value to the period registers, `periodl` and `periodh`.
- An internal counter counts down to zero, and whenever it reaches zero, it is immediately reloaded from the period registers.

- A processor can read the current counter value by first writing to either `snapl` or `snaph` to request a coherent snapshot of the counter, and then reading `snapl` and `snaph` for the full 32-bit value.
- When the count reaches zero:
  - If IRQs are enabled, an IRQ is generated
  - The (optional) pulse-generator output is asserted for one clock period
  - The (optional) watchdog output resets the system

## Avalon-MM Slave Interface

The timer core implements a simple Avalon-MM slave interface to provide access to the register file. The Avalon-MM slave port uses the `resetrequest` signal to implement watchdog timer behavior. This signal is a non-maskable reset signal, and it drives the reset input of all Avalon-MM peripherals in the SOPC Builder system. When the `resetrequest` signal is asserted, it forces any processor connected to the system to reboot. For more information, refer to [“Configuring the Timer as a Watchdog Timer” on page 16–5](#).

## Device and Tools Support

The timer core supports all Altera® FPGA families.

## Instantiating the Core in SOPC Builder

Designers use the MegaWizard® interface for the timer core in SOPC Builder to specify the hardware features. This section describes the options available in the MegaWizard interface.

### Timeout Period

The **Timeout Period** setting determines the initial value of the `periodl` and `periodh` registers. When the **Writeable period** setting is enabled, a processor can change the value of the period by writing `periodl` and `periodh`. When **Writeable period** (see below) is off, the period is fixed and cannot be updated at runtime.

The **Timeout Period** is an integer multiple of the **Timer Frequency**. The **Timer Frequency** is fixed at the frequency setting of the system clock associated with the timer. The **Timeout Period** setting can be specified in units of **µs** (microseconds), **ms** (milliseconds), **seconds**, or **clocks** (number of cycles of the system clock associated with the timer). The actual period depends on the frequency of the system clock associated with the timer. If the period is specified in **µs**, **ms**, or **seconds**, the true period will be the smallest number of clock cycles that is greater or equal

to the specified **Timeout Period** value. For example, if the associated system clock has a frequency of 30 ns, and the specified **Timeout Period** value is 1  $\mu$ s, then the true timeout period will be 1.020 microseconds.

## Hardware Options

The following options affect the hardware structure of the timer core. As a convenience, the **Preset Configurations** list offers several pre-defined hardware configurations, such as:

- **Simple periodic interrupt**—This configuration is useful for systems that require only a periodic IRQ generator. The period is fixed and the timer cannot be stopped, but the IRQ can be disabled.
- **Full-featured**—This configuration is useful for embedded processor systems that require a timer with variable period that can be started and stopped under processor control.
- **Watchdog**—This configuration is useful for systems that require watchdog timer to reset the system in the event that the system has stopped responding. Refer to “[Configuring the Timer as a Watchdog Timer](#)” on page 16–5.

### Register Options

Table 16–1 shows the settings that affect the timer core’s registers.

<b>Option</b>	<b>Description</b>
Writeable period	When this option is enabled, a master peripheral can change the count-down period by writing <code>periodl</code> and <code>periodh</code> . When disabled, the count-down period is fixed at the specified <b>Timeout Period</b> , and the <code>periodl</code> and <code>periodh</code> registers do not exist in hardware.
Readable snapshot	When this option is enabled, a master peripheral can read a snapshot of the current count-down. When disabled, the status of the counter is detectable only via other indicators, such as the <code>status</code> register or the IRQ signal. In this case, the <code>snaph</code> and <code>snaph</code> registers do not exist in hardware, and reading these registers produces an undefined value.
Start/Stop control bits	When this option is enabled, a master peripheral can start and stop the timer by writing the START and STOP bits in the <code>control</code> register. When disabled, the timer runs continuously. When the <b>System reset on timeout (watchdog)</b> option is enabled, the START bit is also present, regardless of the <b>Start/Stop control bits</b> option.

## Output Signal Options

Table 16–2 shows the settings that affect the timer core’s output signals.

Option	Description
Timeout pulse (1 clock wide)	When this option is enabled, the timer core outputs a signal <code>timeout_pulse</code> . This signal pulses high for one clock cycle whenever the timer reaches zero. When disabled, the <code>timeout_pulse</code> signal does not exist.
System reset on timeout (watchdog)	When this option is enabled, the timer core’s Avalon-MM slave port includes the <code>resetrequest</code> signal. This signal pulses high for one clock cycle (causing a system-wide reset) whenever the timer reaches zero. When this option is enabled, the internal timer is stopped at reset. Explicitly writing the <code>START</code> bit of the <code>control</code> register starts the timer. When this option is disabled, the <code>resetrequest</code> signal does not exist. Refer to “ <a href="#">Configuring the Timer as a Watchdog Timer</a> ”.

## Configuring the Timer as a Watchdog Timer

To configure the timer for use as a watchdog, in the MegaWizard interface select **Watchdog** in the **Preset Configurations** list, or choose the following settings:

- Set the **Timeout Period** to the desired “watchdog” period.
- Turn off **Writeable period**.
- Turn off **Readable snapshot**.
- Turn off **Start/Stop control bits**.
- Turn off **Timeout pulse**.
- Turn on **System reset on timeout (watchdog)**.

A watchdog timer wakes up (i.e., comes out of reset) stopped. A processor later starts the timer by writing a 1 to the `control` register’s `START` bit. Once started, the timer can never be stopped. If the internal counter ever reaches zero, the watchdog timer resets the system by generating a pulse on its `resetrequest` output. To prevent the system from resetting, the processor must periodically reset the timer’s count-down value by writing either the `periodl` or `periodh` registers (the written value is ignored). If the processor fails to access the timer because, for example, software stopped executing normally, then the watchdog timer resets the system and returns the system to a defined state.

## Software Programming Model

The following sections describe the software programming model for the timer core, including the register map and software declarations to access the hardware. For Nios II processor users, Altera provides hardware abstraction layer (HAL) system library drivers that enable you to access the timer core using the HAL application programming interface (API) functions.

### HAL System Library Support

The Altera-provided drivers integrate into the HAL system library for Nios II systems. When possible, HAL users should access the timer via the HAL API, rather than accessing the timer registers.

Altera provides a driver for both the HAL timer device models: system clock timer, and timestamp timer.

#### *System Clock Driver*

When configured as the system clock, the timer runs continuously in periodic mode, using the default period set in SOPC builder. The system clock services are then run as a part of the interrupt service routine for this timer. The driver is interrupt-driven, and therefore must have its interrupt signal connected in the system hardware.

The Nios II integrated development environment (IDE) allows you to specify system library properties that determine which timer device will be used as the system clock timer.

#### *Timestamp Driver*

The timer core may be used as a timestamp device if it meets the following conditions:

- The timer has a writeable `period` register, as configured in SOPC Builder.
- The timer is not selected as the system clock.

The Nios II IDE allows you to specify system library properties that determine which timer device will be used as the timestamp timer.

If the timer hardware is not configured with writeable `period` registers, then calls to the `alt_timestamp_start()` API function will not reset the timestamp counter. All other HAL API calls will perform as expected.

For more information about using the system clock and timestamp features that use these drivers, refer to the *Nios II Software Developer's Handbook*. The Nios II Embedded Design Suite (EDS) also provides several example designs that use the timer core.

### Limitations

The HAL driver for the timer core does not support the watchdog reset feature of the timer core.

### Software Files

The timer core is accompanied by the following software files. These files define the low-level interface to the hardware, and provide the HAL drivers. Application developers should not modify these files.

- **altera\_avalon\_timer\_regs.h**—This file defines the core's register map, providing symbolic constants to access the low-level hardware.
- **altera\_avalon\_timer.h, altera\_avalon\_timer\_sc.c, altera\_avalon\_timer\_ts.c, altera\_avalon\_timer\_vars.c**—These files implement the timer device drivers for the HAL system library.

### Register Map

A programmer should never have to directly access the timer via its registers if using the standard features provided in the HAL system library for the Nios II processor. In general, the register map is only useful to programmers writing a device driver.

The Altera-provided HAL device driver accesses the device registers directly. If you are writing a device driver, and the HAL driver is active for the same device, your driver will conflict and fail to operate correctly.

Table 16–3 shows the register map for the timer.

Offset	Name	R/W	Description of Bits						
			15	...	4	3	2	1	0
0	status	RW	(1)					RUN	TO
1	control	RW	(1)		STOP	START	CONT	ITO	
2	periodl	RW	Timeout Period – 1 (bits 15..0)						
3	periodh	RW	Timeout Period – 1 (bits 31..16)						

**Table 16–3. Register Map (Part 2 of 2)**

Offset	Name	R/W	Description of Bits						
			15	...	4	3	2	1	0
4	snapl	RW	Counter Snapshot (bits 15..0)						
5	snaph	RW	Counter Snapshot (31..16)						

Note to [Table 16–3](#):

- (1) Reserved. Read values are undefined. Write zero.

### *status Register*

The `status` register has two defined bits, as shown in [Table 16–4](#).

**Table 16–4. status Register Bits**

Bit	Name	Read/Write/Clear	Description
0	TO	RC	The TO (timeout) bit is set to 1 when the internal counter reaches zero. Once set by a timeout event, the TO bit stays set until explicitly cleared by a master peripheral. Write zero to the <code>status</code> register to clear the TO bit.
1	RUN	R	The RUN bit reads as 1 when the internal counter is running; otherwise this bit reads as 0. The RUN bit is not changed by a write operation to the <code>status</code> register.

### *control Register*

The `control` register has four defined bits, as shown in [Table 16–5](#).

**Table 16–5. control Register Bits (Part 1 of 2)**

Bit	Name	Read/Write/Clear	Description
0	ITO	RW	If the ITO bit is 1, the timer core generates an IRQ when the <code>status</code> register's TO bit is 1. When the ITO bit is 0, the timer does not generate IRQs.
1	CONT	RW	The CONT (continuous) bit determines how the internal counter behaves when it reaches zero. If the CONT bit is 1, the counter runs continuously until it is stopped by the STOP bit. If CONT is 0, the counter stops after it reaches zero. When the counter reaches zero, it reloads with the 32-bit value stored in the <code>periodl</code> and <code>periodh</code> registers, regardless of the CONT bit.

**Table 16–5. control Register Bits (Part 2 of 2)**

Bit	Name	Read/ Write/ Clear	Description
2	START (1)	W	Writing a 1 to the START bit starts the internal counter running (counting down). The START bit is an event bit that enables the counter when a write operation is performed. If the timer is stopped, writing a 1 to the START bit causes the timer to restart counting from the number currently held in its counter. If the timer is already running, writing a 1 to START has no effect. Writing 0 to the START bit has no effect.
3	STOP (1)	W	Writing a 1 to the STOP bit stops the internal counter. The STOP bit is an event bit that causes the counter to stop when a write operation is performed. If the timer is already stopped, writing a 1 to STOP has no effect. Writing a 0 to the stop bit has no effect. Writing 0 to the STOP bit has no effect. If the timer hardware is configured with <b>Start/Stop control bits</b> off, writing the STOP bit has no effect.

**Note to Table 16–5:**

(1) Writing 1 to both START and STOP bits simultaneously produces an undefined result.

*periodl and periodh Registers*

The `periodl` and `periodh` registers together store the timeout period value. `periodl` holds the least-significant 16 bits, and `periodh` holds the most-significant 16 bits. The internal counter is loaded with the 32-bit value stored in `periodh` and `periodl` whenever one of the following occurs:

- A write operation to either the `periodh` or `periodl` register
- The internal counter reaches 0

The timer's actual period is one cycle greater than the value stored in `periodh` and `periodl`, because the counter assumes the value zero (0x00000000) for one clock cycle.

Writing to either `periodh` or `periodl` stops the internal counter, except when the hardware is configured with **Start/Stop control bits** off. If **Start/Stop control bits** is off, writing either register does not stop the counter. When the hardware is configured with **Writeable period** disabled, writing to either `periodh` or `periodl` causes the counter to reset to the fixed **Timeout Period** specified at system generation time.

### *snapl and snaph Registers*

A master peripheral may request a coherent snapshot of the current 32-bit internal counter by performing a write operation (write-data ignored) to either the `snapl` or `snaph` registers. When a write occurs, the value of the counter is copied to `snapl` and `snaph`. `snapl` holds the least-significant 16 bits of the snapshot and `snaph` holds the most-significant 16 bits. The snapshot occurs whether or not the counter is running. Requesting a snapshot does not change the internal counter's operation.

### **Interrupt Behavior**

The timer core generates an IRQ whenever the internal counter reaches zero and the ITO bit of the `control` register is set to 1. Acknowledge the IRQ in one of two ways:

- Clear the TO bit of the `status` register
- Disable interrupts by clearing the ITO bit of the `control` register

Failure to acknowledge the IRQ produces an undefined result.

## Core Overview

The system ID core with Avalon<sup>®</sup> interface is a simple read-only device that provides SOPC Builder systems with a unique identifier. Nios<sup>®</sup> II processor systems use the system ID core to verify that an executable program was compiled targeting the actual hardware image configured in the target FPGA. If the expected ID in the executable does not match the system ID core in the FPGA, it is possible that the software will not execute correctly.

This chapter contains the following sections:

- “Functional Description” on page 17-1
- “Device and Tools Support” on page 17-2
- “Instantiating the Core in SOPC Builder” on page 17-2
- “Software Programming Model” on page 17-3

## Functional Description

The system ID core provides a read-only Avalon Memory-Mapped (Avalon-MM) slave interface. This interface has two registers, as shown in [Table 17-1](#).

<i>Table 17-1. System ID Core Register Map</i>			
Offset	Register Name	R/W	Bit Description
			31...0
0	id	R	SOPC Builder System ID (1)
1	timestamp	R	SOPC Builder Generation Time (1)

*Note to Table 17-1:*

(1) Return value is constant.

The value of each register is determined at system generation time, and always returns a constant value. The meaning of the values is:

- `id`— A unique 32-bit value that is based on the contents of the SOPC Builder system. The `id` is similar to a check-sum value; SOPC Builder systems with different components, different configuration options, or both, produce different `id` values.

- `timestamp`—A unique 32-bit value that is based on the system generation time. The value is equivalent to the number of seconds after Jan. 1, 1970.

There are two basic ways to use the system ID core:

- Verify the system ID before downloading new software to a system. This method is used by software development tools, such as the Nios II integrated development environment (IDE). There is little point in downloading a program to a target hardware system, if the program is compiled for different hardware. Therefore, the Nios II IDE checks that the system ID core in hardware matches the expected system ID of the software before downloading a program to run or debug.
- Check system ID after reset. If a program is running on hardware other than the expected SOPC Builder system, then the program may fail to function altogether. If the program does not crash, it can behave erroneously in subtle ways that are difficult to debug. To protect against this case, a program can compare the expected system ID against the system ID core, and report an error if they do not match.

## Device and Tools Support

The system ID core supports all device families supported by SOPC Builder. The system ID core provides a device driver for the Nios II hardware abstraction layer (HAL) system library. No software support is provided for any other processor, including the first-generation Nios processor.

## Instantiating the Core in SOPC Builder

The System ID core has no user-configurable features. The `id` and `timestamp` register values are determined at system generation time based on the configuration of the SOPC Builder system and the current time. You can add only one system ID core to an SOPC Builder system, and its name is always `sysid`.

After system generation, you can examine the values stored in the `id` and `timestamp` registers by opening the MegaWizard® Plug-In Manager interface for the System ID core. Hovering the mouse over the component in SOPC Builder also displays a tool-tip showing the values.

## Software Programming Model

This section describes the software programming model for the system ID core. For Nios II processor users, Altera provides the HAL system library header file that defines the system ID core registers.

The System ID core comes with the following software files. These files provide low-level access to the hardware. Application developers should not modify these files.

- **alt\_avalon\_sysid\_regs.h**—Defines the interface to the hardware registers.
- **alt\_avalon\_sysid.c, alt\_avalon\_sysid.h**—Header and source files defining the hardware access functions.

Altera provides one access routine, `alt_avalon_sysid_test()`, that returns a value indicating whether the system ID expected by software matches the system ID core.

## alt\_avalon\_sysid\_test()

<b>Prototype:</b>	<code>alt_32 alt_avalon_sysid_test(void)</code>
<b>Thread-safe:</b>	No.
<b>Available from ISR:</b>	Yes.
<b>Include:</b>	<code>&lt;altera_avalon_sysid.h&gt;</code>
<b>Description:</b>	Returns 0 if the values stored in the hardware registers match the values expected by software. Returns 1 if the hardware timestamp is greater than the software timestamp. Returns -1 if the software timestamp is greater than the hardware timestamp.

## Core Overview

The Avalon® memory-mapped (Avalon-MM) phase locked loop (PLL) core with Avalon interface provides a means of accessing the dedicated on-chip PLL circuitry in Altera’s Stratix® and Cyclone® series FPGAs. The PLL core is a component wrapper around the Altera® altpll Megafunction.

The core takes an SOPC Builder system clock as its input and generates PLL output clocks locked to that reference clock.

The PLL core supports the following features:

- All PLL features provided by Altera’s altpll megafunction. The exact feature set depends on the device family.
- Access to status and control signals via Avalon-MM registers or top-level signals on the SOPC Builder system module.

The PLL output clocks are made available in two ways:

- As sources to system-wide clocks in your SOPC Builder system
- As output signals on your SOPC Builder system module

For details about the altpll megafunction, refer to the *altpll Megafunction User Guide*.

The PLL core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. This chapter contains the following sections:

- “Functional Description” on page 18–2
- “Device and Tools Support” on page 18–3
- “Instantiating the Core in SOPC Builder” on page 18–4
- “Hardware Simulation Considerations” on page 18–6
- “Register Definitions and Bit List” on page 18–6

## Functional Description

Figure 18–1 shows a block diagram of the PLL core and its connection to the PLL circuitry inside an Altera FPGA. The following sections describe the components of the core.

Figure 18–1. PLL Core Block Diagram

### altpll Megafunction

The PLL core consists of an altpll megafunction instantiation and an Avalon-MM slave interface. This interface can optionally provide access to status and control registers within the core. The altpll Megafunction takes an SOPC Builder system clock as its reference, and generates one or more phase-locked output clocks.

## Clock Outputs

Depending on the target device family, the *altpll* Megafunction can produce two types of output clock:

- internal (c)—clock outputs that can drive logic either inside or outside the SOPC Builder system module. Internal clock outputs can also be mapped to top-level FPGA pins. Internal clock outputs are available on all device families.
- external (e)—clock outputs that can only drive dedicated FPGA pins. They can not be used as on-chip clock sources. External clock outputs are not available on all device families.

To determine the exact number and type of output clocks available on your target device, refer to the *altpll Megafunction User Guide*.

## PLL Status and Control Signals

Depending on how the *altpll* megafunction is parameterized, there can be a variable number of status and control signals. You can choose to export certain status and control signals to the top-level SOPC Builder system module. Alternatively, Avalon-MM registers can provide access to the signals. Any status or control signals which are not mapped to registers are exported to the top-level module. For details, refer to the [“Instantiating the Core in SOPC Builder” on page 18-4](#).

## System Reset Considerations

At FPGA configuration, the PLL core resets automatically. PLL-specific reset circuitry guarantees that the PLL locks before releasing reset for the overall SOPC Builder system module.

Resetting the PLL resets the entire SOPC Builder system module.

## Device and Tools Support

The PLL core is supported by the Quartus II software version 5.1 and later. The core supports any Altera FPGA family supported by the *altpll* megafunction.

For more information about the *altpll* megafunction, refer to the *altpll Megafunction User Guide*.

## Instantiating the Core in SOPC Builder

The PLL core contains an instantiation of the `altpll` Megafunction. The MegaWizard® interface for the PLL core allows you to configure the `altpll`, and specify connections to selected `altpll` status and control signals. The PLL core appears in the **Other** category in the SOPC Builder list of available components.

The following sections describe the options available in the MegaWizard interface for the Avalon-MM PLL core in SOPC Builder.

### PLL Settings Page

The **PLL Settings** page contains a button that launches Altera's `altpll` MegaWizard Plug-In Manager. Use the MegaWizard interface to parameterize the `altpll` megafunction. The set of available parameters depends on the target device family.

For details about using the `altpll` MegaWizard interface, refer to the *altpll Megafunction User Guide*.

You cannot click **Finish** in the Avalon-MM PLL wizard nor configure the PLL interface until you parameterize the `altpll` megafunction.

### Interface Page

The **Interface** page configures the access modes for the optional advanced PLL status and control signals.

For each advanced signal present on the `altpll`, you can select one of the following access modes:

- **Export**—Exports the signal to the top level of the SOPC builder system module.
- **Register**—Maps the signal to a bit in a status or control register.

The advanced signals are optional. If you choose not to create any of them in the `altpll` MegaWizard, the PLL's default behavior will be as shown in [Table 18-1](#).

You can specify the access mode for the advanced signals shown in [Table 18–1](#). The `altpll` core signals, not displayed in this table, are automatically exported to the top level of the SOPC Builder system module.

**Table 18–1. altpll Advanced Signals**

altpll Name	Input / Output	Avalon-MM PLL Wizard Name	Default Behavior	Description
<code>areset</code>	input	PLL Reset Input	The PLL is reset only at device configuration.	This signal resets the entire SOPC Builder system module, and restores the PLL to its initial settings.
<code>pllenna</code>	input	PLL Enable Input	The PLL is enabled.	This signal enables the PLL. <code>pllenna</code> is always exported.
<code>pfdena</code>	input	PFD Enable Input	The phase-frequency detector is enabled.	This signal enables the phase-frequency detector in the PLL, allowing it to lock on to changes in the clock reference.
<code>locked</code>	output	PLL Locked Output	—	This signal is asserted when the PLL is locked to the input clock.

Asserting `areset` resets the entire SOPC Builder system module, not just the PLL.

## Finish

Click **Finish** to insert the PLL into the SOPC Builder system. The PLL clock output(s) appear in the clock settings table on the SOPC Builder **System Contents** tab.

If the PLL has external output clocks, they appear in the clock settings table like other clocks; however, you cannot use them to drive components within the SOPC Builder system.

For details about using external output clocks, refer to the *altpll Megafunction User Guide*.

The SOPC Builder automatically connects the PLL's reference clock input to the first available clock in the clock settings table.

If there is more than one SOPC Builder system clock available, verify that the PLL is connected to the appropriate reference clock.

## Hardware Simulation Considerations

The HDL files generated by SOPC Builder for the PLL core are suitable for both synthesis and simulation. The PLL core supports the standard SOPC Builder simulation flow, so there are no special considerations for hardware simulation.

## Register Definitions and Bit List

Table 18–2 shows the register map for the PLL core. Device drivers can control and communicate with the core through two 16-bit memory-mapped registers, `status` and `control`.

Note that the status and control bits shown below are present only if they have been created in the altpll MegaWizard, and set to **Register** on the **Interface** page in the PLL wizard.

Offset	Register Name	R/W	Bit Description			
			15	...	2	1
0	<code>status</code>	R/O	(1)			LOCKED
1	<code>control</code>	R/W	(1)		PFDENA	ARESET

*Note to Table 18–2:*

(1) Reserved. Read values are undefined. When writing, set reserved bits to zero.

## Status Register

Embedded software can access the PLL status via the `status` register. Writing to `status` has no effect. Table 18–3 describes the function of each bit.

Bit Number	Bit Name	Value after reset	Description
0	LOCKED	1	Connects to the <code>locked</code> signal on the altpll. The LOCKED bit is high when valid clocks are present on the output of the PLL.
1 .. 15	—	—	Reserved. Read values are undefined.

## Control Register

Embedded software can control the PLL via the `control` register. Software can also read back the status of control bits. [Table 18–4](#) describes the function of each bit.

<i>Table 18–4. Control Register Bits</i>			
Bit Number	Bit Name	Value after reset	Description
0	ARESET	0	Connects to the <code>areset</code> signal on the <code>altpll</code> . Writing a 1 to this bit asserts the <code>areset</code> signal for one clock cycle.
1	PFDENA	1	Connects to the <code>pfdena</code> signal on the <code>altpll</code> .
2 .. 15	—	—	Reserved. Read values are undefined. When writing, set reserved bits to zero.

## Referenced Document

This chapter references the [altpll Megafunction User Guide](#).

## Document Revision History

Table 18–5 shows the revision history for this chapter.

## Core Overview

The performance counter core with Avalon<sup>®</sup> interface enables relatively unobtrusive, real-time profiling of software programs. With the performance counter, you can accurately measure execution time taken by multiple sections of code. You need only add a single instruction at the beginning and end of each section to be measured.

The main benefit of using the performance counter core is the accuracy of the profiling results. Alternatives include the following approaches:

- GNU profiler, `gprof`—`gprof` provides broad low-precision timing information about the entire software system. It uses a substantial amount of RAM, and degrades the real-time performance. For many embedded applications, `gprof` distorts real-time behavior too much to be useful.
- Interval timer peripheral—The interval timer is less intrusive than `gprof`. It can provide good results for narrowly targeted sections of code.

The performance counter core is unobtrusive, requiring only a single instruction to start and stop profiling, and no RAM. It is appropriate for high-precision measurements of narrowly targeted sections of code.

For further discussion of all three profiling methods, refer to *AN 391: Profiling Nios II Systems*.

The performance counter core is SOPC Builder-ready and integrates easily into any SOPC Builder-generated system. The core is designed for use in Avalon-based processor systems, such as a Nios<sup>®</sup> II processor system. Altera<sup>®</sup> provides device drivers to enable the Nios II processor to use the performance counters.

This chapter contains the following sections:

- “Functional Description” on page 19–2
- “Device and Tools Support” on page 19–4
- “Instantiating the Core in SOPC Builder” on page 19–4
- “Hardware Simulation Considerations” on page 19–4
- “Software Programming Model” on page 19–5
- “Performance Counter API” on page 19–8

## Functional Description

The performance counter core is a set of counters which track clock cycles, timing multiple sections of your software. You can start and stop these counters in your software, individually or as a group. You can read cycle counts from hardware registers.

The core contains two counters for every section:

- Time: A 64-bit clock cycle counter
- Events: A 32-bit event counter

### Section Counters

Each 64-bit time counter records the aggregate number of clock cycles spent in a section of code. The 32-bit event counter records the number of times the section executes.

The performance counter core can have up to seven section counters.

### Global Counter

The global counter controls all section counters. The section counters are enabled only when the global counter is running.

The 64-bit global clock cycle counter tracks the aggregate time for which the counters were enabled. The 32-bit global event counter tracks the number of global events, that is, the number of times the performance counter core has been enabled.

## Register Map

The performance counter core has a simple Avalon Memory-Mapped (Avalon-MM) slave interface that provides access to memory-mapped registers. Reading from the registers retrieves the current times and event counts. Writing to the registers starts, stops and resets the counters.

Table 19–1 shows the registers in detail.

<b>Table 19–1. Performance Counter Core Register Map</b>				
Offset	Register Name	Bit Description		
		Read	Write	
		31 ... 0	31 ... 1	0
0	T[0] <sub>lo</sub>	global clock cycle counter [31: 0]	(1)	0 = STOP 1 = RESET
1	T[0] <sub>hi</sub>	global clock cycle counter [63:32]	(1)	0 = START
2	Ev[0]	global event counter	(1)	(1)
3	–	(1)	(1)	(1)
4	T[1] <sub>lo</sub>	section 1 clock cycle counter [31: 0]	(1)	0 = STOP
5	T[1] <sub>hi</sub>	section 1 clock cycle counter [63:32]	(1)	0 = START
6	Ev[1]	section 1 event counter	(1)	(1)
7	–	(1)	(1)	(1)
8	T[2] <sub>lo</sub>	section 2 clock cycle counter [31: 0]	(1)	0 = STOP
9	T[2] <sub>hi</sub>	section 2 clock cycle counter [63:32]	(1)	0 = START
10	Ev[2]	section 2 event counter	(1)	(1)
11	–	(1)	(1)	(1)
.	.	.	.	.
.	.	.	.	.
.	.	.	.	.
4n + 0	T[n] <sub>lo</sub>	section n clock cycle counter [31: 0]	(1)	0 = STOP
4n + 1	T[n] <sub>hi</sub>	section n clock cycle counter [63:32]	(1)	0 = START
4n + 2	Ev[n]	section n event counter	(1)	(1)
4n + 3	–	(1)	(1)	(1)

Note to Table 19–1:

(1) Reserved. Read values are undefined. When writing, set reserved bits to zero.

## System Reset Considerations

After system reset, the performance counter core is stopped and disabled, and all counters contain zero.

## Device and Tools Support

The performance counter core supports all Altera device families supported by SOPC Builder, and provides device drivers for the Nios II hardware abstraction layer (HAL) system library.

## Instantiating the Core in SOPC Builder

Designers use the MegaWizard® interface for the performance counter core in SOPC Builder to specify the core's hardware features.

### Define Counters

Choose the number of section counters you want to generate by selecting from the "**Number of simultaneously-measured sections**" list. The performance counter core may have up to seven sections. If you require more than seven sections, you can instantiate multiple performance counter cores.

### Multiple Clock Domain Considerations

If your SOPC Builder system uses multiple clocks, place the performance counter core in the same clock domain as the CPU. Otherwise, it is not possible to convert cycle counts to seconds correctly.

## Hardware Simulation Considerations

You can use this core in simulation with no special considerations.

## Software Programming Model

The following sections describe the software programming model for the performance counter core.

### Software Files

Altera provides the following software files for Nios II systems. These files define the low-level access to the hardware and provide control and reporting functions. Do not modify these files.

- `altera_avalon_performance_counter.h`, `altera_avalon_performance_counter.c`—The header and source code for the functions and macros needed to control the performance counter core and retrieve raw results.
- `perf_print_formatted_report.c`—The source code for simple profile reporting.

### Using the Performance Counter

In a Nios II system, you can control the performance counter core with a set of highly efficient C macros, and extract the results with C functions.

#### API Summary

The Nios II application program interface (API) for the performance counter core consists of functions, macros and constants.

#### Functions and macros

Table 19–2 lists macros and functions for accessing the performance counter hardware structure.

<b>Name</b>	<b>Summary</b>
<code>PERF_RESET()</code>	Stops and disables all counters, resetting them to 0.
<code>PERF_START_MEASURING()</code>	Starts the global counter and enables section counters.
<code>PERF_STOP_MEASURING()</code>	Stops the global counter and disables section counters.
<code>PERF_BEGIN()</code>	Starts timing a code section.
<code>PERF_END()</code>	Stops timing a code section.
<code>perf_print_formatted_report()</code>	Sends a formatted summary of the profiling results to stdout.
<code>perf_get_total_time()</code>	Returns the aggregate global profiling time in clock cycles.
<code>perf_get_section_time()</code>	Returns the aggregate time for one section in clock cycles.

**Table 19–2. Performance Counter Macros and Functions**

Name	Summary
perf_get_num_starts()	Returns the number of counter events.
alt_get_cpu_freq()	Returns the CPU frequency in Hz.

For a complete description of each macro and function, see “Performance Counter API” on page 19–8.

**Hardware constants**

You can get the performance counter hardware parameters from constants defined in **system.h**. The constant names are based on the performance counter instance name, specified on the **System Contents** tab in SOPC Builder. Table 19–3 lists the hardware constants.

**Table 19–3. Performance Counter Constants**

Name (1)	Meaning
PERFORMANCE_COUNTER_BASE	Base address of core
PERFORMANCE_COUNTER_SPAN	Number of hardware registers
PERFORMANCE_COUNTER_HOW_MANY_SECTIONS	Number of section counters

*Note to Table 19–3:*

- (1) Example based on instance name performance\_counter

*Startup*

Before using the performance counter core, invoke PERF\_RESET to stop, disable and zero all counters.

*Global Counter Usage*

Use the global counter to enable and disable the entire performance counter core. For example, you might choose to leave profiling disabled until your software has completed its initialization.

*Section Counter Usage*

To measure a section in your code, surround it with the macros PERF\_BEGIN() and PERF\_END(). These macros consist of a single write to the performance counter core.

You can simultaneously measure as many code sections as you like, up to the number specified in SOPC Builder. See “[Define Counters](#)” on [page 19–4](#) for details. You can start and stop counters individually, or as a group.

Typically, you assign one counter to each section of code you intend to profile. However, in some situation you may wish to group several sections of code in a single section counter. As an example, to measure general interrupt overhead, you can measure all interrupt service routines (ISRs) with one counter.

To avoid confusion, assign a mnemonic symbol for each section number.

For an example, refer to the performance checksum design files accompanying *AN 391: Profiling Nios II Systems*. These files may be found on the Altera Nios II literature page at [www.altera.com/literature/lit-nio2.jsp](http://www.altera.com/literature/lit-nio2.jsp).

### *Viewing Counter Values*

Library routines allow you to retrieve and analyze the results. Use `perf_print_formatted_report()` to list the results to `stdout` as shown in [Example 19–1](#).

---

#### **Example 19–1.**

```
perf_print_formatted_report(  
    (void *)PERFORMANCE_COUNTER_BASE, // Peripheral's HW base address  
    alt_get_cpu_freq(),               // defined in "system.h"  
    3,                                // How many sections to print  
    "1st checksum_test",              // Display-names of sections  
    "pc_overhead",  
    "ts_overhead");
```

---

[Example 19–2](#) creates a table similar to this result.

**Example 19–2.**

```
--Performance Counter Report--
Total Time: 2.07711 seconds (103855534 clock-cycles)
+-----+-----+-----+-----+-----+
| Section          |      % | Time (sec) | Time (clocks) | Occurrences |
+-----+-----+-----+-----+-----+
| 1st_checksum_test |     50 | 1.03800    | 51899750      | 1           |
+-----+-----+-----+-----+-----+
| pc_overhead      | 1.73e-05 | 0.00000    | 18            | 1           |
+-----+-----+-----+-----+-----+
| ts_overhead      | 4.24e-05 | 0.00000    | 44            | 1           |
+-----+-----+-----+-----+-----+
```

For full documentation of `perf_print_formatted_report()`, see [“Performance Counter API” on page 19–8](#).

### Interrupt Behavior

The performance counter core does not generate interrupts.

You can start and stop performance counters, and read raw performance results, in an interrupt service routine (ISR). Do not call function `perf_print_formatted_report()` from an ISR.

If an interrupt occurs during the measurement of a section of code, the time taken by the CPU to process the interrupt and return to the section is added to the measurement time. The same applies to context switches in a multithreaded environment. Your software must take appropriate measures to avoid or handle these situations.

## Performance Counter API

This section describes the application programming interface (API) for the performance counter core.

For Nios II processor users, Altera provides routines to access the performance counter core hardware. These functions are specific to the performance counter core and directly manipulate low level hardware. The performance counter core cannot be accessed via the HAL API or the ANSI C standard library.

## PERF\_RESET()

**Prototype:** `PERF_RESET(p)`

**Thread-safe:** Yes

**Available from ISR:** Yes

**Include:** `<altera_avalon_performance_counter.h>`

**Parameters:** `p`—performance counter core base address

**Returns:** —

**Description:** Macro `PERF_RESET()` stops and disables all counters, resetting them to 0.

## PERF\_START\_MEASURING()

<b>Prototype:</b>	<code>PERF_START_MEASURING (p)</code>
<b>Thread-safe:</b>	Yes
<b>Available from ISR:</b>	Yes
<b>Include:</b>	<code>&lt;altera_avalon_performance_counter.h&gt;</code>
<b>Parameters:</b>	<code>p</code> —performance counter core base address
<b>Returns:</b>	—
<b>Description:</b>	Macro <code>PERF_START_MEASURING ()</code> starts the global counter, enabling the performance counter core. The behavior of individual section counters is controlled by <code>PERF_BEGIN ()</code> and <code>PERF_END ()</code> . <code>PERF_START_MEASURING ()</code> defines the start of a global event, and increments the global event counter. This macro is a single write to the performance counter core.

## PERF\_STOP\_MEASURING()

<b>Prototype:</b>	PERF_STOP_MEASURING (p)
<b>Thread-safe:</b>	Yes
<b>Available from ISR:</b>	Yes
<b>Include:</b>	<altera_avalon_performance_counter.h>
<b>Parameters:</b>	p—performance counter core base address
<b>Returns:</b>	—
<b>Description:</b>	Macro PERF_STOP_MEASURING () stops the global counter, disabling the performance counter core. This macro is a single write to the performance counter core.

## PERF\_BEGIN()

<b>Prototype:</b>	PERF_BEGIN( <i>p</i> , <i>n</i> )
<b>Thread-safe:</b>	Yes
<b>Available from ISR:</b>	Yes
<b>Include:</b>	<altera_avalon_performance_counter.h>
<b>Parameters:</b>	<i>p</i> —performance counter core base address <i>n</i> —counter section number. Section counter numbers start at 1. Do not refer to counter 0 in this macro.
<b>Returns:</b>	—
<b>Description:</b>	Macro PERF_BEGIN() starts the timer for a code section, defining the beginning of a section event, and incrementing the section event counter. If you subsequently use PERF_STOP_MEASURING() and PERF_START_MEASURING() to disable and re-enable the core, the section counter will resume. This macro is a single write to the performance counter core.

## PERF\_END()

<b>Prototype:</b>	PERF_END (p, n)
<b>Thread-safe:</b>	Yes
<b>Available from ISR:</b>	Yes
<b>Include:</b>	<altera_avalon_performance_counter.h>
<b>Parameters:</b>	p—performance counter core base address n—counter section number. Section counter numbers start at 1. Do not refer to counter 0 in this macro.
<b>Returns:</b>	—
<b>Description:</b>	Macro PERF_END () stops timing a code section. The section counter does not run, regardless whether the core is enabled or not. This macro is a single write to the performance counter core.

## perf\_print\_formatted\_report()

**Prototype:**

```
int perf_print_formatted_report (
    void* perf_base,
    alt_u32 clock_freq_hertz,
    int num_sections, ...)
```

**Thread-safe:** No

**Available from ISR:** No

**Include:** <altera\_avalon\_performance\_counter.h>

**Parameters:**

- `perf_base`—performance counter core base address
- `clock_freq_hertz`—clock frequency
- `num_sections`—The number of section counters to display. This must not exceed <instance\_name>\_HOW\_MANY\_SECTIONS.

**Returns:** 0

**Description:** Function `perf_print_formatted_report()` reads the profiling results from the performance counter core, and prints a formatted summary table. This function disables all counters. However, for predictable results in a multi-threaded or interrupt environment, invoke `PERF_STOP_MEASURING()` when you reach the end of the code to be measured, rather than relying on `perf_print_formatted_report()`.

This function requires the C standard library. Do not use the small C library with this function.

## perf\_get\_total\_time()

<b>Prototype:</b>	<code>alt_u64 perf_get_total_time(void* hw_base_address)</code>
<b>Thread-safe:</b>	No
<b>Available from ISR:</b>	Yes
<b>Include:</b>	<code>&lt;altera_avalon_performance_counter.h&gt;</code>
<b>Parameters:</b>	<code>hw_base_address</code> —base address of performance counter core
<b>Returns:</b>	Aggregate global time in clock cycles
<b>Description:</b>	Function <code>perf_get_total_time()</code> reads the raw global time. This is the aggregate time, in clock cycles, that the performance counter core has been enabled. This function has the side effect of stopping the counters.

## perf\_get\_section\_time()

**Prototype:** `alt_u64 perf_get_section_time  
(void* hw_base_address, int which_section)`

**Thread-safe:** No

**Available from ISR:** Yes

**Include:** `<altera_avalon_performance_counter.h>`

**Parameters:** `hw_base_address`—performance counter core base address  
`which_section`—counter section number

**Returns:** Aggregate section time in clock cycles

**Description:** Function `perf_get_section_time()` reads the raw time for a given section. This is the time, in clock cycles, that the section has been running. This function has the side effect of stopping the counters.

## perf\_get\_num\_starts()

**Prototype:** `alt_u32 perf_get_num_starts  
(void* hw_base_address, int which_section)`

**Thread-safe:** Yes

**Available from ISR:** Yes

**Include:** `<altera_avalon_performance_counter.h>`

**Parameters:** `hw_base_address`—performance counter core base address  
`which_section`—counter section number

**Returns:** Number of counter events

**Description:** Function `perf_get_num_starts()` retrieves the number of counter events (or times a counter has been started). If `which_section = 0`, it retrieves the number of global events (times the performance counter core has been enabled). This function does not stop the counters.

## alt\_get\_cpu\_freq()

**Prototype:** alt\_u32 alt\_get\_cpu\_freq()  
**Thread-safe:** Yes.  
**Available from ISR:** Yes.  
**Include:** <altera\_avalon\_performance\_counter.h>  
**Parameters:**  
**Returns:** CPU frequency in Hz  
**Description:** Function alt\_get\_cpu\_freq() returns the CPU frequency in Hz.

## Document Revision History

Table 19–4 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>
October 2007 v7.2.0	<ul style="list-style-type: none"> <li>Chapter 19 was formerly chapter 17</li> <li>Removed incorrect statement about granularity of the timer.</li> </ul>	—
May 2007 v7.1.0	<ul style="list-style-type: none"> <li>Chapter 17 was formerly chapter 15.</li> <li>Added table of contents to Overview section.</li> <li>Added Referenced Documents section.</li> </ul>	—
March 2007 v7.0.0	No change from previous release.	—
November 2006 v6.1.0	<ul style="list-style-type: none"> <li>Updated Avalon terminology because of changes to Avalon technologies</li> <li>Changed old “Avalon switch fabric” term to “system interconnect fabric”</li> <li>Changed old “Avalon interface” terms to “Avalon Memory-Mapped interface”</li> </ul>	For the 6.1 release, Altera released the Avalon Streaming interface, which necessitated some re-phrasing of existing Avalon terminology.
May 2006 v6.0.0	No change from previous release.	—
December 2005 v5.1.0	Initial release.	—

---

This section describes streaming peripherals provided by Altera® for SOPC Builder systems. These components allow you to optimize streaming applications.

Refer to *About This Handbook* for further details.

This section includes the following chapter:

- [Chapter 20, Avalon Streaming Channel Multiplexer and Demultiplexer Cores](#)
- [Chapter 21, Avalon Streaming Test Pattern Generator and Checker Cores](#)

For information about the revision history for chapters in this section, refer to each individual chapter for that chapter's revision history.

### Core Overview

The Avalon® streaming (Avalon-ST) channel multiplexer receives data from a number of input interfaces and multiplexes the data into a single output interface, using the optional `channel` signal to indicate which input the output data is from. The Avalon-ST channel demultiplexer receives data from a channelized input interface and drives that data to multiple output interfaces, where the output interface is selected by the input `channel` signal.

The multiplexer and demultiplexer can transfer data between interfaces on cores that support the unidirectional flow of data. The multiplexer and demultiplexer allow you to create multiplexed or demultiplexed datapaths without having to write custom HDL code to perform these functions. The multiplexer includes a round-robin scheduler. Both cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system. This chapter contains the following sections:

- “Multiplexer” on page 20–3
- “Demultiplexer” on page 20–6
- “Device and Tools Support” on page 20–8
- “Installation and Licensing” on page 20–9
- “Hardware Simulation Considerations” on page 20–9
- “Software Programming Model” on page 20–9

## Resource Usage and Performance

Resource utilization for the cores depends upon the number of input and output interfaces, the width of the datapath and whether the streaming data uses the optional packet protocol. For the multiplexer, the parameterization of the scheduler also effects resource utilization.

Table 20–1 provides estimated resource utilization for eleven different configurations of the multiplexer.

**Table 20–1. Multiplexer Estimated Resource Usage and Performance**

No. of Inputs	Data Width	Scheduling Size (Cycles)	Stratix® II and Stratix II GX (Approximate LEs)		Cyclone® II		Stratix	
			f <sub>MAX</sub> (MHz)	ALM Count	f <sub>MAX</sub> (MHz)	Logic Cells	f <sub>MAX</sub> (MHz)	Logic Cells
2	Y	1	500	31	420	63	422	80
2	Y	2	500	36	417	60	422	58
2	Y	32	451	43	364	68	360	49
8	Y	2	401	150	257	233	228	298
8	Y	32	356	151	219	207	211	123
16	Y	2	262	333	174	533	170	284
16	Y	32	310	337	161	471	157	277
2	N	1	500	23	400	48	422	52
2	N	9	500	30	420	52	422	56
11	N	9	292	275	197	397	182	287
16	N	9	262	295	182	441	179	224

Table 20–2 provides estimated resource utilization for six different configurations of the demultiplexer. The core operating frequency varies with the device, the number of interfaces and the size of the datapath.

**Table 20–2. Demultiplexer Estimated Resource Usage**

No. of Inputs	Data Width (Symbols per Beat)	Stratix II (Approximate LEs)		Cyclone II		Stratix II GX (Approximate LEs)	
		f <sub>MAX</sub> (MHz)	ALM Count	f <sub>MAX</sub> (MHz)	Logic Cells	f <sub>MAX</sub> (MHz)	Logic Cells
2	1	500	53	400	61	399	44
15	1	349	171	235	296	227	273
16	1	363	171	233	294	231	290
2	2	500	85	392	97	381	71
15	2	352	247	213	450	210	417
16	2	328	280	218	451	222	443

## Multiplexer

This section describes the hardware structure and functionality of the multiplexer component.

### Functional Description

The Avalon-ST multiplexer takes data from a number of input data interfaces, and multiplexes the data onto a single output interface. The mux includes a simple, round-robin scheduler that selects from the next input interface that has data. Each input interface has the same width as the output interface, so that all other input interfaces are backpressured when the mux is carrying data from a different input interface.

The mux includes an optional `channel` signal that enables each input interface to carry channelized data. When the `channel` signal is present on input interfaces, the mux adds  $\log_2(\text{num\_input\_interfaces})$  bits to make the output channel signal, such that the output channel signal has all of the bits of the input channel plus the bits required to indicate which input interface each cycle of data is from. These bits are appended to either the most or least significant bits of the output `channel` signal as specified in the SOPC Builder MegaWizard® interface (Figure 20–1).

Figure 20–1. Multiplexer

The internal scheduler considers one input interface at a time, selecting it for transfer. Once an input interface has been selected, data from that input interface is sent until one of the following scenarios occurs:

- The specified number of cycles have elapsed
- The input interface has no more data to send and de-asserts `valid` on a ready cycle
- The packets are supported, `endofpacket` is asserted

### *Input Interfaces*

Each input interface is an Avalon-ST data interface that optionally supports packets. The input interfaces are identical; they have the same symbol and data widths, error widths, and channel widths.

### *Output Interface*

The output interface carries the multiplexed data stream with data from all of the inputs. The symbol, data, and error widths are the same as the input interfaces. The width of the `channel` signal is the same as the input interfaces, with the addition of the bits needed to indicate the input each datum was from.

## Instantiating the Multiplexer in SOPC Builder

Use the MegaWizard interface for the multiplexer core in SOPC Builder to specify the core configuration. The following sections list the available options in the MegaWizard interface.

**Functional Parameters**—The following sections outline the options for the multiplexer as a whole:

- **Number of Input Ports**—The number of input interfaces that the multiplexer supports. Valid values are 2 .. 16.
- **Scheduling Size (Cycles)**—The number of cycles that are sent from a single channel before changing to the next channel.
- **Use high bits to indicate source port**—When selected, the high bits of the output channel signal are used to indicate the input interface that the data came from. For example, if the input interfaces have 4-bit channel signals, and the mux has 4 input interfaces, then the output interface has a 6-bit channel signal. If this parameter is true, bits [5:4] of the output channel signal indicate the input interface the data is from, and bits [3:0] are the channel bits that were presented at the input interface.

**Output Interface**—The following sections outline the options for the output interface:

- **Data Bits Per Symbol**—The number of bits per symbol for the input and output interfaces. Valid values are 1 – 32 bits.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat (transfer). Valid values are 1 – 32.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**—The number of bits used for the channel signal for input interfaces. A value of 0 indicates that input interfaces do not have channels. A value of 4 indicates that up to 16 channels share the same input interface. The input channel can have a width between 0-31 bits. A value of 0 means that the optional channel signal is not used.
- **Error Signal Width (bits)**—The width of the `error` signal for input and output interfaces. A value of 0 means the `error` signal is not used.

# Demultiplexer

This section describes the hardware structure and functionality of the demultiplexer component.

## Functional Description

That Avalon-ST demultiplexer takes data from a channelized input data interface and provides that data to multiple output interfaces, where the output interface selected for a particular transfer is specified by the input `channel` signal. The data is delivered to the output interfaces in the same order it was received at the input interface, regardless of the value of `channel`, `packet`, `frame`, or any other signal. Each of the output interfaces has the same width as the input interface, so that each output interface will be idle when the demux is driving data to a different output interface. The demux uses  $\log_2(\text{num\_output\_interfaces})$  bits of the `channel` signal to select the output to which to forward the data; the remainder of the channel bits are forwarded to the appropriate output interface unchanged (Figure 20–2).

**Figure 20–2. The Demultiplexer**

### *Input Interface*

Each input interface is an Avalon-ST data interface that optionally supports packets.

### *Output Interfaces*

Each output interface carries data from a subset of channels from the input interface. Each output interface is identical; all have the same symbol and data widths, error widths, and channel widths. The symbol, data, and error widths are the same as the input interface. The width of the `channel` signal is the same as the input interface, without the bits that were used to select the output interface.

## Instantiating the Demultiplexer in SOPC Builder

Use the MegaWizard interface for the demultiplexer core in SOPC Builder to specify the core configuration. The following sections list the available options in the MegaWizard interface.

**Functional Parameters**—The following sections outline the options for the demultiplexer as a whole:

- **Number of Output Ports**—The number of output interfaces that the multiplexer supports. Valid values are 2 .. 16.
- **High channel bits select output**—When selected, the high bits of the input channel signal are used by the de-multiplexing function and the low order bits are passed to the output. When not selected, the low order bits are used and the high order bits are passed through.

The following example illustrates the significance of the location of these signals. In [Figure 20-3](#) there is one input interface and two output interfaces. If the low-order bits of the channel signal select the output interfaces, the even channels will go to channel 0 and the odd channels will go to channel 1. If the high-order bits of the channel signal select the output interface, channels 0-7 will go to channel 0 and channels 8-15 will go to channel 1.

**Figure 20-3. Select Bits for Demultiplexer**

**Input Interface**—The following sections outline the options for the input interface.

- **Data Bits Per Symbol** - The number of bits per symbol for the input and output interfaces. Valid values are 1 – 32 bits.
- **Data Symbols Per Beat** - The number of symbols (words) that are transferred per beat (transfer). Valid values are 1 – 32.

- **Include Packet Support** - Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Channel Signal Width (bits)**- The number of bits used for the `channel` signal for output interfaces. A value of 0 means that output interfaces do not use the optional `channel` signal.
- **Error Signal Width (bits)** - The width of the `error` signal for input and output interfaces. A value of 0 means the `error` signal is not unused.

## Device and Tools Support

Altera device support for the multiplexer and demultiplexer components is listed in [Table 20-3](#). For each device family, a component provides either full or preliminary support:

- *Full support* means the component meets all functional and timing requirements for the device family and may be used in production designs.
- *Preliminary support* means the component meets all functional requirements, but might still be undergoing timing analysis for the device family; it may be used in production designs with caution.

<b>Table 20-3. Device Family Support</b>		
<b>Device Family</b>	<b>Avalon-ST Multiplexer</b>	<b>Avalon-ST Demultiplexer</b>
Arria™ GX	Preliminary	Preliminary
Cyclone III	Preliminary	Preliminary

Cyclone	Full	Full
HardCopy® II	Full	Full
Stratix III	Preliminary	Preliminary
Stratix II GX	Full	Full
Stratix II	Full	Full
Stratix GX	Full	Full
Stratix	Full	Full

## Installation and Licensing

The multiplexer and demultiplexer components are included in the Altera MegaCore® IP Library, which is an optional part of the Quartus® II software installation. After you install the MegaCore IP Library, SOPC Builder recognizes these components and can instantiate them into a system.

You can use the multiplexer and demultiplexer components for free without a license in any design targeting an Altera device.

## Hardware Simulation Considerations

The multiplexer and demultiplexer components do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

## Software Programming Model

The multiplexer and demultiplexer components do not have any user-visible control or status registers. Therefore software cannot control or configure any aspect of the multiplexer or demultiplexer at run-time. The components cannot generate interrupts.

## Document Revision History

Table 20–4 shows the revision history for this chapter.

<b>Date and Document Version</b>	<b>Changes Made</b>	<b>Summary of Changes</b>

May 2007 v7.1.0	Initial release.	—

## 21. Avalon Streaming Test Pattern Generator and Checker Cores

Q1155007-7.2.0

### Core Overview

The data generation and monitoring solution for Avalon<sup>®</sup> Streaming (Avalon-ST) consists of two components: a test pattern generator core that generates packetized or non-packetized data and sends it out on an Avalon-ST data interface, and a test pattern checker core that receives the same data and checks it for correctness.

The test pattern generator core can insert different error conditions, and the test pattern checker reports these error conditions to the control interface, each via an Avalon Memory-Mapped (Avalon-MM) slave.

Both cores are SOPC Builder-ready and integrate easily into any SOPC Builder-generated system.

This chapter contains the following sections:

- [“Resource Utilization and Performance” on page 21-2](#)
- [“Test Pattern Generator” on page 21-4](#)
- [“Test Pattern Checker” on page 21-6](#)
- [“Device and Tools Support” on page 21-8](#)
- [“Installation and Licensing” on page 21-9](#)
- [“Hardware Simulation Considerations” on page 21-9](#)
- [“Software Programming Model” on page 21-10](#)
- [“Test Pattern Generator API” on page 21-15](#)
- [“Test Pattern Checker API” on page 21-21](#)

## Resource Utilization and Performance

Resource utilization and performance for the test pattern generator and checker cores depend on the datawidth, number of channels, and whether the streaming data uses the optional packet protocol.

Table 21-1 provides estimated resource utilization and performance for the test pattern generator core.

**Table 21-1. Test Pattern Generator Estimated Resource Utilization and Performance**

No. of Channels	Datawidth (No. of 8-bit Symbols Per Beat)	Packet Support	Stratix <sup>®</sup> II and Stratix II GX			Cyclone <sup>®</sup> II			Stratix		
			f <sub>MAX</sub> (MHz)	ALM Count	Memory (bits)	f <sub>MAX</sub> (MHz)	Logic Cells	Memory (bits)	f <sub>MAX</sub> (MHz)	Logic Cells	Memory (bits)
1	4	Yes	284	233	560	206	642	560	202	642	560

## Test Pattern Generator

This section describes the hardware structure and functionality of the test pattern generator core.

### Functional Description

The test pattern generator core accepts commands to generate data via an Avalon-MM command interface, and drives the generated data to an Avalon-ST data interface. You can parameterize most aspects of the Avalon-ST data interface such as the number of error bits and data signal width, thus allowing you to test components with different interfaces. [Figure 21-1](#) shows a block diagram of the test pattern generator core.

**Figure 21-1. Test Pattern Generator Core Block Diagram**

The data pattern is determined by the following equation:  

$$\text{Symbol Value} = \text{Symbol Position in Packet XOR Data Error Mask.}$$
 Non-packetized data is one long stream with no beginning or end.

The test pattern generator core has a throttle register that is set via the Avalon-MM control interface. The value of the throttle register is used in conjunction with a pseudo-random number generator to throttle the data generation rate.

### Command Interface

The command interface is a 32-bit Avalon-MM write slave that accepts data generation commands. It is connected to a 16-element deep FIFO, thus allowing a master peripheral to drive a number of commands into the test pattern generator core.

The command interface maps to the following registers: `cmd_lo` and `cmd_hi`. The command is pushed into the FIFO when the register `cmd_lo` (address 0) is written to. When the FIFO is full, the command

interface asserts the wait request signal. You can create errors by writing to the register `cmd_hi` (address 1). The errors are only cleared when 0 is written to this register or its respective fields. See page “[Test Pattern Generator Command Registers](#)” on page 21–12 for more information on the register fields.

### *Control and Status Interface*

The control and status interface is a 32-bit Avalon-MM slave that allows you to enable or disable the data generation as well as set the throttle.

This interface also provides useful generation-time information such as the number of channels and whether or not packets are supported.

### *Output Interface*

The output interface is an Avalon-ST interface that optionally supports packets. You can configure the output interface to suit your requirements.

Depending on the incoming stream of commands, the output data may contain interleaved packet fragments for different channels. To keep track of the current symbol’s position within each packet, the test pattern generator core maintains an internal state for each channel.

## **Instantiating the Test Pattern Generator in SOPC Builder**

Use the MegaWizard® interface for the test pattern generator core in SOPC Builder to configure the core. The following sections list the available options in the MegaWizard interface.

### *Functional Parameter*

The functional parameter allows you to configure the test pattern generator as a whole: **Throttle Seed**—The starting value for the throttle control random number generator. Altera recommends a value which is unique to each instance of the test pattern generator and checker cores in a system.

### *Output Interface*

You can configure the output interface of the test pattern generator core using the following parameters:

- **Number of Channels**—The number of channels that the test pattern generator core supports. Valid values are 1–256.
- **Data Bits Per Symbol**—The number of bits per symbol for the input and output interfaces. Valid values are 1–256. Example—For typical systems that carry 8-bit bytes, set this parameter to 8.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat. Valid values are 1–256.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Error Signal Width (bits)**—The width of the `error` signal on the output interface. Valid values are 0–31. A value of 0 indicates that the error signal is not in use.

## Test Pattern Checker

This section describes the hardware structure and functionality of the test pattern checker core.

### Functional Description

The test pattern checker core accepts data via an Avalon-ST interface, checks it for correctness against the same predetermined pattern used by the test pattern generator core to produce the data, and reports any exceptions to the control interface. You can parameterize most aspects of the test pattern checker's Avalon-ST interface such as the number of error bits and the data signal width, thus allowing you to test components with different interfaces.

The test pattern checker has a throttle register that is set via the Avalon-MM control interface. The value of the throttle register controls the rate at which data is accepted.

Figure 21–2 shows a block diagram of the test pattern checker core.

**Figure 21–2. Test Pattern Checker**

The test pattern checker core detects exceptions and reports them to the control interface via a 32-element deep internal FIFO. Possible exceptions are data error, missing start-of-packet (SOP), missing end-of-packet (EOP) and signalled error.

As each exception occurs, an exception descriptor is pushed into the FIFO. If the same exception occurs more than once consecutively, only one exception descriptor is pushed into the FIFO. All exceptions are ignored when the FIFO is full. Exception descriptors are deleted from the FIFO after they are read by the control and status interface.

### *Input Interface*

The input interface is an Avalon-ST interface that optionally supports packets. You can configure the input interface to suit your requirements.

Incoming data may contain interleaved packet fragments. To keep track of the current symbol's position, the test pattern checker core maintains an internal state for each channel.

### *Control and Status Interface*

The control and status interface is a 32-bit Avalon-MM slave that allows you to enable or disable data acceptance as well as set the throttle. This interface provides useful generation-time information such as the number of channels and whether the test pattern checker supports packets.

The control and status interface also provides information on the exceptions detected by the test pattern checker core. The interface obtains this information by reading from the exception FIFO.

## Instantiating the Test Pattern Checker in SOPC Builder

Use the MegaWizard interface for the test pattern checker core in SOPC Builder to configure the core. The following sections list the available options in the MegaWizard interface.

### *Functional Parameter*

The functional parameter allows you to configure the test pattern checker as a whole: **Throttle Seed**—The starting value for the throttle control random number generator. Altera recommends a unique value to each instance of the test pattern generator and checker cores in a system.

### *Input Parameters*

You can configure the input interface of the test pattern checker core using the following parameters:

- **Number of Channels**—The number of channels that the test pattern checker core supports. Valid values are 1–256.
- **Data Bits Per Symbol**—The number of bits per symbol for the input interface. Valid values are 1–256.
- **Data Symbols Per Beat**—The number of symbols (words) that are transferred per beat. Valid values are 1–32.
- **Include Packet Support**—Indicates whether or not packet transfers are supported. Packet support includes the `startofpacket`, `endofpacket`, and `empty` signals.
- **Error Signal Width (bits)**—The width of the error signal on the input interface. Valid values are 0–31. A value of 0 indicates that the error signal is not in use.

## Device and Tools Support

For each device family, the test pattern generator and checker cores provide either full or preliminary support:

- *Full support* means the component meets all functional and timing requirements for the device family and may be used in production designs.
- *Preliminary support* means the component meets all functional requirements, but might still be undergoing timing analysis for the device family; it may be used in production designs with caution.

Figure 21–3 shows the level of support offered by the test pattern generator and checker cores to each Altera device family.

**Table 21–3. Device Family Support**

Device Family	Support	
	Test Pattern Generator	Test Pattern Checker
Arria™ GX	Preliminary	Preliminary
Cyclone III	Preliminary	Preliminary
Cyclone II	Full	Full
Cyclone	Full	Full
HardCopy® II	Full	Full
Stratix III	Preliminary	Preliminary
Stratix II GX	Full	Full
Stratix II	Full	Full
Stratix GX	Full	Full
Stratix	Full	Full

## Installation and Licensing

The test pattern generator and checker cores are included in the Altera MegaCore® IP Library, which is an optional part of the Quartus® II software installation. After you install the MegaCore IP Library, SOPC Builder recognizes these components and can instantiate them into a system.

You can use the test pattern generator and checker for free without a license in any design targeting an Altera device.

## Hardware Simulation Considerations

The test pattern generator and checker cores do not provide a simulation testbench for simulating a stand-alone instance of the component. However, you can use the standard SOPC Builder simulation flow to simulate the component design files inside an SOPC Builder system.

## Software Programming Model

This section describes the software programming model for the test pattern generator and checker cores.

### HAL System Library Support

For Nios II processor users, Altera provides HAL system library drivers that enable you to initialize and access the test pattern generator and checker cores. Altera recommends you to use the provided drivers to access the cores instead of accessing the registers directly.

For Nios II IDE users, copy the provided drivers from the following installation folders to your software application directory:

- `<IP installation directory>/ip/sopc_builder_ip/altera_avalon_data_source/HAL`
- `<IP installation directory>/ip/sopc_builder_ip/altera_avalon_data_sink/HAL`

### Software Files

The following software files define the low-level access to the hardware, and provide the routines for the HAL device drivers. Application developers should not modify these files.

- Software files provided with the test pattern generator core:
  - **data\_source\_regs.h**—The header file that defines the test pattern generator's register maps.
  - **data\_source\_util.h, data\_source\_util.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.
- Software files provided with the test pattern checker core:
  - **data\_sink\_regs.h**—The header file that defines the core's register maps.
  - **data\_sink\_util.h, data\_sink\_util.c**—The header and source code for the functions and variables required to integrate the driver into the HAL system library.

### Register Maps

This section describes the register maps for the test pattern generator and checker cores.

### Test Pattern Generator Control and Status Registers

Table 21–4 shows the offset for the test pattern generator control and status registers. Each register is 32 bits wide.

Offset	Register Name
base + 0	status
base + 1	control
base + 2	fill

Table 21–5 describes the status register bits.

Bit(s)	Name	Access	Description
15:0	ID	RO	A constant value of 0x64.
23:16	NUMCHANNELS	RO	The configured number of channels.
30:24	NUMSYMBOLS	RO	The configured number of symbols per beat.
31	SUPPORTPACKETS	RO	A value of 1 indicates packet support.

Table 21–6 describes the control register bits.

Bit(s)	Name	Access	Description
0	ENABLE	RW	Setting this bit to 1 enables the test pattern generator core.
7:1			Reserved
16:8	THROTTLE	RW	Specifies the throttle value which can be between 0 and 256, inclusively. This value is used in conjunction with a pseudorandom number generator to throttle the data generation rate.  Setting THROTTLE to 0 stops the test pattern generator core. Setting it to 256 causes the test pattern generator core to run at full throttle. Values between 0 and 256 result in a data rate proportional to the throttle value.
17	SOFT RESET	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
31:18			Reserved

Table 21–7 describes the fill register bits.

Bit(s)	Name	Access	Description
0	BUSY	RO	A value of 1 indicates that data transmission is in progress, or that there is at least one command in the command queue.
6:1	Reserved		
15:7	FILL	RO	The number of commands currently in the command FIFO.
31:16	Reserved		

### Test Pattern Generator Command Registers

Table 21–8 shows the offset for the command registers. Each register is 32 bits wide.

Offset	Register Name
base + 0	cmd_lo
base + 1	cmd_hi

Table 21–9 describes the cmd\_lo register bits. The command is pushed into the FIFO only when the cmd\_lo register is written to.

Bit(s)	Name	Access	Description
15:0	SIZE	RW	The segment size in symbols. Except for the last segment in a packet, the size of all segments must be a multiple of the configured number of symbols per beat. If this condition is not met, the test pattern generator core inserts additional symbols to the segment to ensure the condition is fulfilled.
29:16	CHANNEL	RW	The channel to send the segment on. If the channel signal is less than 14 bits wide, the low order bits of this register are used to drive the signal.
30	SOP	RW	Set this bit to 1 when sending the first segment in a packet. This bit is ignored when packets are not supported.
31	EOP	RW	Set this bit to 1 when sending the last segment in a packet. This bit is ignored when packets are not supported.

Table 21–10 describes the `cmd_hi` register bits.

Bit(s)	Name	Access	Description
15:0	SIGNALLED ERROR	RW	Specifies the value to drive the <code>error</code> signal. A non-zero value creates a signalled error.
23:16	DATA ERROR	RW	The output data is XORed with the contents of this register to create data errors. To stop creating data errors, set this register to 0.
24	SUPPRESS SOP	RW	Set this bit to 1 to suppress the assertion of the <code>startofpacket</code> signal when the first segment in a packet is sent.
25	SUPPRESS EOP	RW	Set this bit to 1 to suppress the assertion of the <code>endofpacket</code> signal when the last segment in a packet is sent.

### *Test Pattern Checker Control and Status Registers*

Table 21–11 shows the offset for the control and status registers. Each register is 32 bits wide.

Offset	Register Name
base + 0	<code>status</code>
base + 1	<code>control</code>
base + 2	Reserved
base + 3	
base + 4	
base + 5	<code>exception_descriptor</code>
base + 6	<code>indirect_select</code>
base + 7	<code>indirect_count</code>

Table 21–12 describes the status register bits.

Bit(s)	Name	Access	Description
15:0	ID	RO	Contains a constant value of 0x65.
23:16	NUMCHANNELS	RO	The configured number of channels.

**Table 21–12. Status Field Descriptions (Part 2 of 2)**

Bit(s)	Name	Access	Description
30:24	NUMSYMBOLS	RO	The configured number of symbols per beat.
31	SUPPORTPACKETS	RO	A value of 1 indicates packet support.

Table 21–13 describes the control register bits.

**Table 21–13. Control Field Descriptions**

Bit(s)	Name	Access	Description
0	ENABLE	RW	Setting this bit to 1 enables the test pattern checker.
7:1	Reserved		
16:8	THROTTLE	RW	Specifies the throttle value which can be between 0 and 256, inclusively. This value is used in conjunction with a pseudorandom number generator to throttle the data generation rate.  Setting THROTTLE to 0 stops the test pattern generator core. Setting it to 256 causes the test pattern generator core to run at full throttle. Values between 0 and 256 result in a data rate proportional to the throttle value.
17	SOFT RESET	RW	When this bit is set to 1, all internal counters and statistics are reset. Write 0 to this bit to exit reset.
31:18	Reserved		

Table 21–14 describes the exception\_descriptor register bits. If there is no exception, reading this register returns 0.

**Table 21–14. Exception\_descriptor Field Descriptions**

Bit(s)	Name	Access	Description
0	DATA_ERROR	RO	A value of 1 indicates that an error is detected in the incoming data.
1	MISSINGSOP	RO	A value of 1 indicates missing start-of-packet.
2	MISSINGEOP	RO	A value of 1 indicates missing end-of-packet.
7:3	Reserved		
15:8	SIGNALLED ERROR	RO	The value of the error signal.
23:16	Reserved		
31:24	CHANNEL	RO	The channel on which the exception was detected.

Table 21–15 describes the `indirect_select` register bits.

Bit	Bits Name	Access	Description
7:0	INDIRECT CHANNEL	RW	Specifies the channel number that applies to the INDIRECT PACKET COUNT, INDIRECT SYMBOL COUNT, and INDIRECT ERROR COUNT registers.
15:8	Reserved		
31:16	INDIRECT ERROR	RO	The number of data errors that occurred on the channel specified by INDIRECT CHANNEL.

Table 21–16 describes the `indirect_count` register bits.

Bit	Bits Name	Access	Description
15:0	INDIRECT PACKET COUNT	RO	The number of packets received on the channel specified by INDIRECT CHANNEL.
31:16	INDIRECT SYMBOL COUNT	RO	The number of symbols received on the channel specified by INDIRECT CHANNEL.

## Test Pattern Generator API

This section describes the application programming interface (API) for the test pattern generator core. All APIs are currently not available from the interrupt service routine (ISR).

### `data_source_reset()`

**Prototype:** `void data_source_reset(alt_u32 base);`

**Thread-safe:** No.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** `void`

**Description:** This function resets the test pattern generator core including all internal counters and FIFOs. The control and status registers are not reset by this function.

## data\_source\_init()

<b>Prototype:</b>	<code>int data_source_init (alt_u32 base, alt_u32 command_base);</code>
<b>Thread-safe:</b>	No.
<b>Include:</b>	<data_source_util.h>
<b>Parameters:</b>	base—The base address of the control and status slave. command_base—The base address of the command slave.
<b>Returns:</b>	1—Initialization is successful. 0—Initialization is unsuccessful.
<b>Description:</b>	This function performs the following operations to initialize the test pattern generator core: <ul style="list-style-type: none"> <li>• Resets and disables the test pattern generator core.</li> <li>• Sets the maximum throttle.</li> <li>• Clears all inserted errors.</li> </ul>

## data\_source\_get\_id()

<b>Prototype:</b>	<code>int data_source_get_id (alt_u32 base);</code>
<b>Thread-safe:</b>	Yes.
<b>Include:</b>	<data_source_util.h>
<b>Parameters:</b>	base—The base address of the control and status slave.
<b>Returns:</b>	The test pattern generator core's identifier.
<b>Description:</b>	This function retrieves the test pattern generator core's identifier.

## data\_source\_get\_supports\_packets()

<b>Prototype:</b>	<code>int data_source_init (alt_u32 base);</code>
<b>Thread-safe:</b>	Yes.
<b>Include:</b>	<data_source_util.h>
<b>Parameters:</b>	base—The base address of the control and status slave.
<b>Returns:</b>	1—Packets are supported. 0—Packets are not supported.
<b>Description:</b>	This function checks if the test pattern generator core supports packets.

## data\_source\_get\_num\_channels()

**Prototype:**           int  
                          data\_source\_get\_num\_channels(alt\_u32  
                          base);

**Thread-safe:**        Yes.

**Include:**            <data\_source\_util.h>

**Parameters:**       base—The base address of the control and status slave.

**Returns:**            The number of channels supported.

**Description:**       This function retrieves the number of channels supported  
                          by the test pattern generator core.

## data\_source\_get\_symbols\_per\_cycle()

**Prototype:**           int data\_source\_get\_symbols(alt\_u32  
                          base);

**Thread-safe:**        Yes.

**Include:**            <data\_source\_util.h>

**Parameters:**       base—The base address of the control and status slave.

**Returns:**            The number of symbols transferred in a beat.

**Description:**       This function retrieves the number of symbols transferred  
                          by the test pattern generator core in each beat.

## data\_source\_set\_enable()

**Prototype:**           void data\_source\_set\_enable(alt\_u32  
                          base, alt\_u32 value);

**Thread-safe:**        No.

**Include:**            <data\_source\_util.h>

**Parameters:**       base—The base address of the control and status slave.  
                          value—The ENABLE bit is set to the value of this  
                          parameter.

**Returns:**            void

**Description:**       This function enables or disables the test pattern  
                          generator core. When disabled, the test pattern generator  
                          core stops data transmission but continues to accept  
                          commands and stores them in the FIFO.

## data\_source\_get\_enable()

**Prototype:** `int data_source_get_enable(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The value of the `ENABLE` bit.

**Description:** This function retrieves the value of the `ENABLE` bit.

## data\_source\_set\_throttle()

**Prototype:** `void data_source_set_throttle(alt_u32 base, alt_u32 value);`

**Thread-safe:** No.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`value`—The throttle value.

**Returns:** `void`

**Description:** This function sets the throttle value, which can be between 0 and 256 inclusively. The throttle value, when divided by 256 yields the rate at which the test pattern generator sends data.

## data\_source\_get\_throttle()

**Prototype:** `int data_source_get_throttle(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The throttle value.

**Description:** This function retrieves the current throttle value.

## data\_source\_is\_busy()

**Prototype:** `int data_source_is_busy(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** 1—The test pattern generator core is busy.  
0—The core is not busy.

**Description:** This function checks if the test pattern generator is busy. The test pattern generator core is busy when it is sending data or has data in the command FIFO to be sent.

## data\_source\_fill\_level()

**Prototype:** `int data_source_fill_level(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_source_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The number of commands in the command FIFO.

**Description:** This function retrieves the number of commands currently in the command FIFO.

## data\_source\_send\_data()

<b>Prototype:</b>	<pre>int data_source_send_data(alt_u32 cmd_base, alt_u32 channel, alt_u32 size, alt_u32 flags, alt_u32 error, alt_u32 data_error_mask);</pre>
<b>Thread-safe:</b>	No.
<b>Include:</b>	<data_source_util.h>
<b>Parameters:</b>	<p>cmd_base—The base address of the command slave.</p> <p>channel—The channel to send the data on.</p> <p>size—The data size.</p> <p>flags—Specifies whether to send or suppress SOP and EOP signals. Valid values are DATA_SOURCE_SEND_SOP, DATA_SOURCE_SEND_EOP, DATA_SOURCE_SEND_SUPPRESS_SOP and DATA_SOURCE_SEND_SUPPRESS_EOP.</p> <p>error—The value asserted on the error signal on the output interface.</p> <p>data_error_mask—This parameter and the data are XORed together to produce erroneous data.</p>
<b>Returns:</b>	Always returns 1.
<b>Description:</b>	<p>This function sends a data fragment to the specified channel.</p>

If packets are supported, user applications must ensure the following conditions are met:

- SOP and EOP are used consistently in each channel.
- Except for the last segment in a packet, the length of each segment is a multiple of the data width.

If packets are not supported, user applications must ensure the following conditions are met:

- No SOP and EOP indicators in the data.
- The length of each segment in a packet is a multiple of the data width.

## Test Pattern Checker API

This section describes the API for the test pattern checker core. The APIs are currently not available from the ISR.

### data\_sink\_reset()

<b>Prototype:</b>	<code>void data_sink_reset (alt_u32 base);</code>
<b>Thread-safe:</b>	No.
<b>Include:</b>	<code>&lt;data_sink_util.h&gt;</code>
<b>Parameters:</b>	<code>base</code> —The base address of the control and status slave.
<b>Returns:</b>	<code>void</code>
<b>Description:</b>	This function resets the test pattern checker core including all internal counters.

### data\_sink\_init()

<b>Prototype:</b>	<code>int data_source_init (alt_u32 base);</code>
<b>Thread-safe:</b>	No.
<b>Include:</b>	<code>&lt;data_sink_util.h&gt;</code>
<b>Parameters:</b>	<code>base</code> —The base address of the control and status slave.
<b>Returns:</b>	1—Initialization is successful. 0—Initialization is unsuccessful.
<b>Description:</b>	This function performs the following operations to initialize the test pattern checker core: <ul style="list-style-type: none"><li>• Resets and disables the test pattern checker core.</li><li>• Sets the throttle to the maximum value.</li></ul>

### data\_sink\_get\_id()

<b>Prototype:</b>	<code>int data_sink_get_id (alt_u32 base);</code>
<b>Thread-safe:</b>	Yes.
<b>Include:</b>	<code>&lt;data_sink_util.h&gt;</code>
<b>Parameters:</b>	<code>base</code> —The base address of the control and status slave.
<b>Returns:</b>	The test pattern checker core's identifier.
<b>Description:</b>	This function retrieves the test pattern checker core's identifier.

## **data\_sink\_get\_supports\_packets()**

**Prototype:** `int data_sink_init(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** 1—Packets are supported.  
0—Packets are not supported.

**Description:** This function checks if the test pattern checker core supports packets.

## **data\_sink\_get\_num\_channels()**

**Prototype:** `int data_sink_get_num_channels(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The number of channels supported.

**Description:** This function retrieves the number of channels supported by the test pattern checker core.

## **data\_sink\_get\_symbols\_per\_cycle()**

**Prototype:** `int data_sink_get_symbols(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The number of symbols received in a beat.

**Description:** This function retrieves the number of symbols received by the test pattern checker core in each beat.

## data\_sink\_set\_enable()

**Prototype:** `void data_sink_set_enable(alt_u32 base, alt_u32 value);`

**Thread-safe:** No.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`value`—The `ENABLE` bit is set to the value of this parameter.

**Returns:** `void`

**Description:** This function enables the test pattern checker core.

## data\_sink\_get\_enable()

**Prototype:** `int data_sink_get_enable(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The value of the `ENABLE` bit.

**Description:** This function retrieves the value of the `ENABLE` bit.

## data\_sink\_set\_throttle()

**Prototype:** `void data_sink_set_throttle(alt_u32 base, alt_u32 value);`

**Thread-safe:** No.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`value`—The throttle value.

**Returns:** `void`

**Description:** This function sets the throttle value, which can be between 0 and 256 inclusively. The throttle value, when divided by 256 yields the rate at which the test pattern checker receives data.

## data\_sink\_get\_throttle()

**Prototype:** `int data_sink_get_throttle(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The throttle value.

**Description:** This function retrieves the throttle value.

## data\_sink\_get\_packet\_count()

**Prototype:** `int data_sink_get_packet_count(alt_u32 base, alt_u32 channel);`

**Thread-safe:** No.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`channel`—Channel number.

**Returns:** The number of packets received on the given channel.

**Description:** This function retrieves the number of packets received on a given channel.

## data\_sink\_get\_symbol\_count()

**Prototype:** `int data_sink_get_symbol_count(alt_u32 base, alt_u32 channel);`

**Thread-safe:** No.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`channel`—Channel number.

**Returns:** The number of symbols received on the given channel.

**Description:** This function retrieves the number of symbols received on a given channel.

## data\_sink\_get\_error\_count()

**Prototype:** `int data_sink_get_error_count(alt_u32 base, alt_u32 channel);`

**Thread-safe:** No.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.  
`channel`—Channel number.

**Returns:** The number of errors received on the given channel.

**Description:** This function retrieves the number of errors received on a given channel.

## data\_sink\_get\_exception()

**Prototype:** `int data_sink_get_exception(alt_u32 base);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `base`—The base address of the control and status slave.

**Returns:** The first exception descriptor in the exception FIFO.  
0—No exception descriptor found in the exception FIFO.

**Description:** This function retrieves the first exception descriptor in the exception FIFO and pops it off the FIFO.

## data\_sink\_exception\_is\_exception()

**Prototype:** `int data_sink_exception_is_exception(int exception);`

**Thread-safe:** Yes.

**Include:** `<data_sink_util.h>`

**Parameters:** `exception`—Exception descriptor

**Returns:** 1—Indicates an exception.  
0—No exception.

**Description:** This function checks if a given exception descriptor describes a valid exception.

## **data\_sink\_exception\_has\_data\_error()**

**Prototype:**           int  
                  data\_sink\_exception\_has\_data\_error(int  
                  exception);

**Thread-safe:**        Yes.

**Include:**            <data\_sink\_util.h>

**Parameters:**       exception—Exception descriptor

**Returns:**            1—Data has errors.  
                      0—No errors.

**Description:**       This function checks if a given exception indicates  
                      erroneous data.

## **data\_sink\_exception\_has\_missing\_sop()**

**Prototype:**           int  
                  data\_sink\_exception\_has\_missing\_sop(int  
                  exception);

**Thread-safe:**        Yes.

**Include:**            <data\_sink\_util.h>

**Parameters:**       exception—Exception descriptor.

**Returns:**            1—Missing SOP.  
                      0—Other exception types.

**Description:**       This function checks if a given exception descriptor  
                      indicates missing SOP.

## **data\_sink\_exception\_has\_missing\_eop()**

**Prototype:**           int  
                  data\_sink\_exception\_has\_missing\_eop(int  
                  exception);

**Thread-safe:**        Yes.

**Include:**            <data\_sink\_util.h>

**Parameters:**       exception—Exception descriptor.

**Returns:**            1—Missing EOP.  
                      0—Other exception types.

**Description:**       This function checks if a given exception descriptor  
                      indicates missing EOP.

## data\_sink\_exception\_signalled\_error()

**Prototype:**           int  
                           data\_sink\_exception\_signalled\_error(int  
                           exception);

**Thread-safe:**        Yes.

**Include:**            <data\_sink\_util.h>

**Parameters:**       exception—Exception descriptor.

**Returns:**            The signalled error value.

**Description:**       This function retrieves the value of the signalled error  
                           from the exception.

## data\_sink\_exception\_channel()

**Prototype:**           int data\_sink\_exception\_channel(int  
                           exception);

**Thread-safe:**        Yes.

**Include:**            <data\_sink\_util.h>

**Parameters:**       exception—Exception descriptor.

**Returns:**            The channel number on which the given exception  
                           occurred.

**Description:**       This function retrieves the channel number on which a  
                           given exception occurred.
